this study were diagnosed by the veterinarians as dystocia and were unsuccessfully managed by mutations or fetotomy. The inspection data, camel and farm identification and the cause of dystocia were recorded. Information pertaining to the sick camel examined during the study was collected. This includes identity of camel, housing and management, concurrent disease, body weight, age, duration of dystocia, previous dystocia history, feed intake and medication of camel. Seventy two camels presented at the time of operation have poor health status and six camel cases are under shock condition, since they had severe dystocia due to emphysematous (4 cases) and macerated (2 cases) fetus. A new procedure of caesarian section has been applied in Arabian camels. This included preoperative preparation, operative site, restrains and anesthesia, surgical technique, post operative care, operative and post-operative complications of dam. Data were analyzed using Freq procedure of SAS (2004). Frequency and percentages were calculated and tested by chi square test.

Results: Out of seventy eight outpatient camels under caesarian section, the overall percentage of dam survival was 92.31% (72/78), with significant differences among different breeds (P=0.0286). The highest percentage was in Hazmi and Crossbred (100.00%, each respectively) followed by Omani 93.18% and Sudani breed 70.00% (Table. 1). Observations with regard to the percentage of fetal survival after caesarian section were also recorded (Table 1). The percentage of fetal survival was 28.21% (22/78) with no significant differences among breeds (P=0.3390). Data summarized in Table 2 indicated a highly significant differences (P=0.0001) in the fetal survival between the different age groups, while no significant (P=0.2796) differences in the dam survival was found between the age groups. Post operative complications are presented in Table 3. Two suture types (chromic catgut usp 3 and Safil no. 3) were used for caesarean section in the present study. Infected wounds (33.33%) and abdominal hernia (22.22%) were the main postoperative complications. Numerically, Safil no. 3 was more effective suture used in the caesarian sections than chromic catgut usp 3 (P: 0.4075 and 0.079, for infected wounds and abdominal hernia, respectively). The percentage of wound infection (36.73% and 27.59%) and abdominal hernia (28.89% and 11.11%) used chromic catgut usp 3 and Safil no. 3, respectively.

Conclusions: Left ventro-lateral oblique incision is the most preferable approach for caesarian section in camels. Safil no. 3 was more effective suture used in the caesarian sections than chromic catgut usp 3. No significant difference on dam survival was found using the two suture types. The successful outcomes of caesarian section in camels in our study suggested that good health of the dam, adequate pre and post operative preparation, safety anesthesia, and perfect surgical technique are the most important key elements that redound to minimize the detrimental postoperative complications and high dam survival.

Camelids

Dose recommendations for effective treatment of endoparasitism in South American Camelids

Agnes Dadak¹Sonja Franz² and Research group Veterinary Pharmacology and Therapeutics

¹Institute of Pharmacology, Department of Biomedical Sciences, ²Clinic for Ruminants, Department for Farm Animals and Veterinary Public Health, University of Veterinary Medicine Vienna, Vienna, Austria

Objectives: Dicrocoeliosis and nematodiasis are major health concerns in South American Camelids farmed in Europe. Prevalence of resistance was reported against benzimidazoles and macrocyclic lactones. Albendazole which can be used to treat dicrocoeliosis in other species has been reported to be toxic in camelids. In llamas and alpacas, drugs are used in an off-label manner, since no products are licensed for these species. For most drugs no studies on dosing are available. A novel oral formulation enabled a study on dosing praziquantel in llamas infected with *Dicrocoelium dendriticum* and monepantel was evaluated to treat gastrointestinal nematodiasis.

Materials and Methods: Study procedures were discussed and approved by the institutional ethics committee of the University of Veterinary Medicine Vienna in accordance with Good Scientific Practice Guidelines and national legislation.

53 llamas of mixed sex were included in the praziquantel study (S1) and 46 llamas in the monepantel study (S2). Faecal examinations confirmed natural infection with the respective parasite of interest. Animals were weighed and randomly allocated to one of the treatment groups or the control group. Animals of treatment groups in S1 were dosed orally using a praziquantel-containing paste specifically produced for high-dose treatment (250 mg/ml) at a dose of either 25 mg/kg BW PO (group 1) or 50 mg/kg BW PO (group 2). Monepantel (Zolvix, Novartis Healthcare, Denmark) was dosed orally in S2 at the dose rate recommended for sheep (2.5 mg/kg BW, group 1), 5 mg/kg BW (group 2), or 7.5 mg/kg BW (group 3). Untreated control groups were used for monitoring natural changes in egg counts during the studies. Faecal samples were collected directly from the rectum of each animal before and 14 days after treatment and examined on the same day or stored at 4°C for processing next day. The employees performing faecal examinations were not aware of the treatment status of the respective animals. Criteria for efficacy were faecal egg count reduction (FECR %) and extensity effect (EE %). The FEC was determined by using a modified McMaster technique with a lower threshold of 25 eggs per gram.

Results: In S1 the mean BW (\pm SD) of animals of groups 1 and 2 were 122.6 \pm 27.7 kg and 113.6 \pm 25.9 kg, respectively. Llamas of the control group had a mean BW of 104.6 \pm 32.8 kg. In S2 the mean BW (\pm SD) of animals of groups 1, 2 and 3 were 110.4 \pm 43.9, 120.1 \pm 31.7 kg and 113.6 \pm 25.9 kg BW, respectively. Llamas of the control group had a mean BW of 109.4 \pm 41.9 kg.

None of the animals (S1, S2) showed adverse reactions to the treatment including changes in appetite, attitude, physical activity, urination or defecation as reported by the owners.

Praziquantel treatment in S1 led to a mean FECR of 85% in animals of group 1 with an EE of 67% whereas therapy in group 2 led to a mean FECR of 91% with an EE of 81% implying that almost twice the number of animals of group 1 still shed eggs two weeks after treatment compared with group 2.

Monepantel treatment in S2 led to a mean FECR of 84% with an EE of only 25% in group 1. Mean FECR obtained from animals in group 2 was 93% with an EE of 67%. Animals of group 3 were all tested negative for gastrointestinal nematodes two weeks after treatment (FECR: 100%, EE: 100%).

Conclusions: Results of S1 indicate that 50 mg/kg BW oral praziquantel is required for efficacious dosing against *Dicrocoelium dendriticum* in SAC. The novel drug formulation using a high concentration of praziquantel in a small volume of palatable paste is suitable for applying the required high amount of praziquantel safely.

The results of S2 show that monepantel is highly effective when administered at 7.5 mg/kg BW. The dose rate recommended for sheep (2.5 mg/kg BW) did not lead to effective results. Even at a dose rate of 5 mg/kg BW, monepantel turned out to be underdosed. Thus monepantel is recommended at a dose rate of 7.5mg/kg BW in SAC.

Intraocular melanoma in a 10-year-old female llama

Theresa Tschoner¹*Katja Voigt¹Almuth Falkenau²Melanie Feist¹

¹Clinic for Ruminants with Ambulatory and Herd Health Services , Center for Clinical Veterinary Medicine, 85764 Oberschleissheim, ²Institute of Veterinary Pathology, 80539 Munich, Germany

Objectives: The objective of the presented study is the description of the surgical treatment of an intraocular melanoma in a 10-year-old female llama with a continually growing mass associated with the left eye.

Materials and Methods: A female llama was presented to the Clinic for Ruminants with a continually growing mass associated with the left eye, which had first been observed five months previously. The llama's general condition was good; the left eye showed severe exophthalmus. The cornea was completely covered by an ulcerating mass which obstructed the view on deeper ocular structures. The lens could not be seen at all. An ophthalmological examination was performed to exclude the possibilities of a foreign body in the eye, a fungal infection, intraocular cysts or a parasitic disease such as nematodiasis. The suspected diagnosis was an intraocular tumor. As the llama's general condition was good without indication of a spreading of the disease when doing a thorough clinical examination, enucleation of the left eye was considered the best surgical treatment. This operation was performed under general anaesthesia.

Results: Enucleation is a technically easy operation, enabling surgeons to reduce painful processes within the area of the eye and to stop the progression of neoplastic structures. The operation was performed without the occurrence of any complications. After the enucleation, histological examination was carried out. The mass was characterized as an amelanotic melanoma. The Antibiotic and analgesic therapy was continued after the operation for four days, and the patient was discharged to go home 10 days after the enucleation. As these tumors are known to lead to spreading to the regional lymphatic nodes, especially in humans and dogs, a clinical examination was performed seven months later. The llama was in good health and showed no problems in the herd because of the unilateral blindness. An inquiry by telephone 14 months later revealed that the llama is still in good health.

Conclusions: The most common reason for eye diseases in camelids is trauma, but ocular diseases caused by tumors have been increasingly reported in these species. Intraocular tumors can be classified as either melanocytomas (non-malignant) or melanomas (malignant). As the whole eye was affected without any physiological structures left, the possibility of a non-perforating keratectomy was not considered, but an enucleation of the affected eye was performed. The mass was characterized as an amelanotic melanoma. There are only a few publications on melanomas in new world camelids, but spreading metastases of the tumor are also possible in these species.

Comments: The literature lies with the author.

Camel Toxoplasmosis: Seroprevalence and Zoonotic aspects in Cholistan desert Pakistan

Muhammad Avais¹*Hafiz Zia U. Rehman¹Jawaria A. Khan¹Muti U. Rehman Khan²

¹Department of Clinical Medicine and Surgery, University of Veterinary and Animal Sciences, Lahore, Pakistan, ²Department of Pathology, University of Veterinary and Animal Sciences, Lahore, Pakistan, Lahore, Pakistan

Objectives: Toxoplasmosis is a parasitic zoonosis with worldwide distribution caused by *Toxoplasma gondii* and is demonstrated in domestic livestock, wild life, other animals and humans. Camel milk and meat is consumed in Pakistan and Cholistan desert area is considered as a hub and native place for the camels. The present study was carried out to determine the prevalence and zoonotic potential of camel toxoplasmosis in Cholistan desert area, Bahawalpur.

Materials and Methods: Serum samples from 226 camels and 226 humans (n=113 camel keepers; n=113 humans with no contact history to camels) were collected and analyzed for anti-toxoplasma-antibodies. Data about each camel and human were entered in a "data capture form". The serum samples collected from camels and humans were processed for anti-toxoplasma antibodies by using Latex Agglutination Test (LAT) at dilutions 1:16, 1:64, 1:128 and 1:256. Finally percentage prevalence was calculated and analysed statistically by Chi square test.

Results: Of the camels tested, 9.73% were seropositive for anti-toxoplasma antibodies at titers of 1:16 or higher. As to gender, 11.1% female camels and 8.69% male camels were positive for anti-toxoplasma antibodies. The highest prevalence (12%) was observed in camels of 11 year or above age group followed in order by 6-10 year (9.8%) and 1-5 year (4.4%). The prevalence of toxoplasmosis was high in the 3rd trimester of pregnancy (18.1%) while in the 1st and 2nd trimester it was 10.5% and 13.3%, respectively. Overall, 12% humans were seropositive for anti-toxoplasma antibodies. The highest seroprevalence of toxoplasmosis was observed in camel keepers (15.92%) than people with no contact history to camels (7.96%). As to gender, 11.97% women and 11.76% men were seropositive for anti-toxoplasma antibodies. Age related prevalence of anti-toxoplasma antibodies was 15.25% in persons between 31-40 years or above age followed in order by 12.8% in 21-30 years, 9.61% in 15-20 years and 5.88% in ≤15 year old age groups.

Conclusions: It was concluded that toxoplasmosis is prevalent among camels in Cholistan desert area of Bahawalpur, Pakistan and their is high risk of transmission of toxoplasmosis to humans having contact with these camels.

P02-002-223

Chylothorax in an alpaca caused by a granulomatous swelling in the lung

Bonnie Valgaeren ¹Kaya Theys ¹Piet Deprez ¹Bart Pardon ¹Linde Gille ¹Laura Van Driessche ¹

¹Internal Medicine and Clinical Biology of the Large Animals, Ghent University, Merelbeke, Belgium

Objectives: A chylothorax (or chyle leak) is a type of pleural effusion. It results from lymph formed in the digestive system called chyle accumulating in the pleural cavity due to either disruption or obstruction of the thoracic duct.

The objective of the present study was to describe a case of chylothorax in an alpaca.

Materials and Methods: A 3-year old female alpaca, 10 months in gestation, was presented with the complaint of anorexia since 3 days, and a suspicion of a uterine torsion. Rectal ultrasound revealed no abnormalities in the uterus. The animal aborted shortly after admission. Clinical examination, blood examination, ultrasound, radiography and computed tomography (CT) was used in the diagnostic work-up of this case.

Clinical examination revealed muffled heart sounds and dyspnea, but no abnormal sounds on auscultation of the lungs. Hematology, blood gas analysis and ionogram were normal, as were kidney- and liver values. Triglycerids in blood were 0.26 mmol/L (reference <0.11 mmol/L). Ultrasound of the thorax revealed a large amount of anechogenic fluid in the thorax. At the ventral aspect of the lung surface, comet-tail artifacts were noticed, indicative for abnormal lung tissue. Under ultrasound guidance the fluid was punctured. The obtained liquid was white with a bluish aspect, and contained a total protein of 40g/l, triglycerids of 1.72 mmol/L, and no cells.

Results: Radiography revealed a higher opacity of the caudoventral lung parts and an alveolar pattern. CT-images indicated a collapse of the left cranial lung lobe, and a remarkable fluid-opacity in the ventral aspect of the thorax, with local foci of a clear alveolar pattern. On both sides of the thorax, there were several pleural noduli. In the right hemithorax, a large space-occupying structure with a size of 12cm in length, 1 cm in width and 2 cm in height was visible.

The macroscopic aspect and high triglyceride in the pleural effusion confirmed chylothorax in this patient. The large structure and different noduli visible on the CT-image suggested the presence of a neoplastic process, although a granulomatous pathology could not be excluded. Granulomas can be caused by chronic bacterial, fungal or viral infections, by aspiration of foreign bodies or by immune mediated reactions.

Two liters of fluid were drained from the thorax using thoracocentesis. Control-ultrasounds revealed no further accumulation of fluid after initial draining. The animal was treated during 1 months with penicillin to treat a potential chronic bacterial pneumonia. General condition gradually improved, and the animal fully recovered. No signs of relapse occurred in a one year telephonic follow-up period.

Conclusions: The authors did not find any previous cases of chylothorax in alpacas in peer-reviewed literature. There were no indications for a traumatic cause in the anamnesis. Abortion only occurred after diagnosis of the fluid in the thorax. In this particular case, the chylothorax was apparently caused by compression of the ductus thoracicus by a mass of unknown nature. The positive evolution after antimicrobial treatment suggests a chronic bacterial pneumonia as the primary cause of this granulomatous swelling in the lung and consecutive chylothorax.

Genetic Background Of Tibial Hemimelia Syndrome In Galloway Cattle

Markus Freick¹, Ekkehard Schütz², Michael Hardt³, Petra Scheuermann³, Brenig Bertram²

¹Veterinary Practice Zettlitz, Zettlitz/Methau, ²Georg-August-University of Göttingen, Institute of Veterinary Medicine, Göttingen, ³Landesuntersuchungsanstalt für das Gesundheits- und Veterinärwesen Sachsen, Leipzig, Germany

Objectives: Tibial hemimelia syndrome (TH) has been reported in single cases in Galloway, Shorthorn or Bunaji cattle. Affected calves are usually stillborn and exhibit multiple anomalies including shortened or absent tibia, agenesis of the patella, abdominal hernia, cryptorchidism, failed Müllerian duct development, hirsutism, meningoencephalocele, and internal hydrocephalus. We hypothesized that the *Aristaless-Like Homeobox 4 Gene (ALX4)* is a candidate gene for TH in Galloway cattle due to its key role in limb development and the identification of causative mutations within this gene in TH cases in humans, mice and Shorthorn cattle.

Materials and Methods: Two Black Galloway calves affected by TH were born in springtime 2014 in a herd of a part-time farmer in Saxony/Germany. Pathological and microbiological investigations, X-ray analysis and maceration of the hind limbs were performed. Tissue samples of the TH affected Galloway calves and 13 hair or blood samples of their relatives were provided for genetic studies by the breeder.

The bovine *ALX4* gene is located on BTA15q28-q29 between positions 74,452,084–74,486,658 Mb and harbours 4 exons coding for a protein of 397 amino acids. For comparison of sequences, exons and adjacent intronic regions were amplified using PCR. PCR products were purified and sequenced using standard protocols. For sequence comparison and identification of sequence variations seven animals of the cattle family including the two affected calves were used. Raw DNA sequence data were manually checked for ambiguities using NC_007313 (Btau 4.6.1) and AC_000172 (UMD3.1) as reference sequence. For *in silico* prediction of splice site mutation effects NNSPLICE 0.9 and Human Splicing Finder were used.

Furthermore, fluorescence resonance energy transfer (FRET) assays were developed for high throughput genotyping of the detected duplications in exon 2 and 4 of *ALX4*. A total of 1688 DNA samples of the most common Galloway varieties (Black/Red/Belted/Riggitt Galloway: GA), and 289 White Galloway (WGA) as well as 876 German Holstein Friesian (HF) and 86 DNA samples of 21 different cattle breeds were randomly selected from the DNA depository of the Institute of Veterinary Medicine Göttingen/Germany and investigated.

Results: Both TH affected Galloway calves were stillborn and showed multiple malformations, i.e. abdominal hernia, arthrogryposis multiplex, and syndromic acerebral macrocephaly. An X-ray analysis and maceration of the hind legs of one calf revealed a specific aplasia of the tibia and the absence of the pubic bone. Infectious causes for the malformation were excluded by negative microbiological and serological analysis of common protozoa, bacteria and viruses in the dams and calves.

From the pedigree analysis an autosomal recessive inheritance of the defect can be predicted. DNA sequence comparison of the coding and flanking intronic regions of the *ALX4* gene revealed 10 SNPs in seven animals of the Galloway cattle family. The SNPs in the coding regions were synonymous mutations. In exon 2 and exon 4 duplications of 20 bp and 34 bp were detected in the affected animals and their parents. Both duplications result in a frameshift leading to a premature stop codon and

truncated protein. The affected calves were homozygous only for the duplication in exon 2. Both cattle were paternal half-siblings. The sire was heterozygous for the duplication in exon 2. The dam of case 1 was carrying both duplications and the mother of case 2 was heterozygous only for the exon 2 duplication.

The duplications were only detected in Galloway cattle. In GA the exon 2 duplication allele frequency was 0.01 and the exon 4 duplication allele frequency was 0.23. WGA showed higher frequencies for both duplications with 0.06 and 0.38, respectively.

Conclusions: In Shorthorn cattle, a DNA-based test for TH is available based on the US patent US 8,158,356 B2, claiming a large deletion of more than 129 kb of BTA15q (75.18–75.31 Mb) including exon 1 of the bovine *ALX4* gene. Since this deletion differs from the mutation identified here, the test is not applicable in Galloway cattle. We identified a duplication of 20 bp in exon 2 of the *ALX4* gene resulting in a frameshift and disruption of helix III of the homeodomain as causative mutation for TH in Galloway cattle. Now it will be possible to test the population using the established FRET assay and implement genotyping results into breeding programs.

Cerebrospinal fluid analysis of 30 ruminants with central nervous system diseases

Antonio Câmara^{1*}, Jose Renato J. Borges¹, Andre M. D. Vale², Benito Soto-Blanco³

¹Hospital Escola de Grandes Animais da Granja do Torto, Universidade de Brasília, Brasília, ²Universidade Federal Rural do Semi-Árido, Mossoró, ³Escola de Veterinária, Universidade Federal de Minas Gerais, Belo Horizonte, Brazil

Objectives: Ruminants may be affected by a wide variety of central nervous system (CNS) diseases, including bacterial, viral and protozoal diseases; toxic and metabolic disorders, trauma or neoplasms. This paper aimed to report the cerebrospinal fluid (CSF) results from 30 ruminants diagnosed with CNS diseases.

Materials and Methods: The medical records of ruminants with CSF analysis of registration were evaluated. The study included thirteen sheep, twelve cows and five goats, totaling 30 ruminants. The cases were included only when the diagnosis was confirmed by the association of epidemiological, clinical, laboratory and histopathological data. In suspected cases of enzootic ataxia and spinal cord trauma, therapeutic diagnosis through supplementation of copper and positive response to the therapy with anti-inflammatory and esteroideais thiamine, confirmed the clinical suspicion, respectively. CSF samples were obtained by puncture of the cerebellomedullary cistern (n=26) or at the lumbosacral site (n=4) after surgical preparation.

Results: In the 30 ruminants examined, the conclusive diagnosis consisted of botulism (8 cases, 26.7%) polioencephalomalacia (5 cases, 16.7%), conidiobolomycosis (3 cases, 10%), suppurative meningitis (3 cases, 10%), pituitary abscesses (3 cases, 10%), spinal cord trauma (3 cases, 10%), meningoencephalitis (2 cases, 6.6%), and single cases of thalamus abscess, myelitis and enzootic ataxia (1 each case, 3.3%). Neutrophilic pleocytosis (20-997 leukocytes/ μ L), presence of fibrin clots and turbid aspect were seen in cases of bacterial infection of the CNS, such as meningoencephalitis, meningitis, cerebral abscesses, myelitis and a case of conidiobolomycosis (fungal infection). In two cases of medullar trauma, CSF analysis showed xanthochromia and presence of phagocytosed red blood cells. All cases of polioencephalomalacia, enzootic ataxia, botulism and two cases of conidiobolomycosis showed no CSF alterations (2-9 leukocytes/ μ L). A case of cervical abscess causing pathological fracture between C5 and T1 vertebrae revealed no changes in CSF analysis, probably because the abscess did not infiltrate to the *dura mater*.

Conclusions: Authors reiterate that evaluation of CSF is a valuable diagnostic tool in association with epidemiological and clinical data for diagnose of CNS diseases in ruminants. The infectious component remains as a important cause of CNS disease in ruminants from Northeastern Brazil.

Biomedical Treatment With The Extract Of Mangosteen To Promote Beneficial Microbiota And Increase Voluntary Feed Intake Of Lactating Calves.

Alejandro Sierra Rizo^{1*} and Eligio Rafael Moreno Gómez, Salvador

Mireles Flores, Cecilia Neri Luna, Gerardo Salazar-Gutiérrez, Jacinto Bañuelos Pineda, Luis Alfonso Guerrero-Quiroz

¹Animal production, Universidad de Guadalajara, Guadalajara, Jalisco, Mexico

Objectives: It is objective was observed in group two effects of mangosteen extract and xanthone 9-xanthene providing greater nutrient intake, important in the physical development of calves when they enter the stage productive area. The perspective with the mangosteen extract and xanthone 9-xanthene pretend stimulated activity against Enterobacteria of the gastrointestinal tract that promotes the intestinal health of nursing calves.

Materials and Methods: Herbal extract the aqueous ethanol solvent, whose components and / or fractions obtained from the mangosteen plant, with antibacterial ability was selected for its effect in vitro inhibition of bacterial group; enterobacteria face in the gastrointestinal tract (GIT) of the animals. The extract of mangosteen (*Garcinia mangostana* Lynn) have antibacterial properties against infections of the respiratory and digestive tract. In this paper the antibacterial activity in vitro was observed for these selected bacteria, the value of the minimum inhibitory concentration (MIC) of mangosteen extract and its fractions; supernatant and precipitate precipitate dehydrated. The farnesiana nanocellulose from Acacia XG® commercial product, 9-xanthene® xanthone and between these and the mixture ranged biomedicamentosos compounds 25, 50 and 100% concentration and 5 to 10 mg / mL respectively. In this work the effect of mangosteen extract administered orally in calves of Holstein-Friesian breed in the infancy period was also observed. Control calves fed milk replacer kalbermilch-premium (trow balance®) group, called three treatments were used. Group 2 calves fed mangosteen extract 25% and 5 mg of xanthone 9-xanthene® in milk replacer, and Group 3 with calves fed 50% mangosteen extract. Weight gain, height calves and quantification of colony forming units (CFU) of pathogenic and non-pathogenic bacteria in infancy: the variables were recorded

Results: The results showed that in the halos of bacterial inhibition for enterobacteria significant difference (P <0.05); The highest value (mm) was in the XG® commercial product (20 \pm 0.6) followed by the mangosteen extract (16 \pm 1.15) xanthone 9-xanthene® (7 \pm 0.73) and nanocellulose (1 \pm 0.12). The results showed that consumption of food concentrate weight per day in group 2 (40.2 \pm 0.1 kg) was significant (P <0.05) than that recorded in the control group (32 \pm 2.3g), but similar to group 3 (36.2 \pm 0.1 kg). Consumption of milk replacer in aqueous solution exists significant difference (P <0.05) in the control group (166 \pm 3.5 L versus 152 \pm 1.2 \pm 2.9 L and 145 L) for group 2 and 3, respectively. The daily weight gain of calves (883 \pm 88.2g, 600 \pm 572 \pm 57.7g 36.5g), no significant difference (P <0.05) between treatments was recorded; Group 2, Group 3 and control, respectively. At the height increase was not significant (P <0.05), it is recorded (89.7 \pm 2.0 cm day⁻¹, 85.7 \pm 3.7 cm day⁻¹ and 85 \pm 0.6 cm day⁻¹) for group 2, the control group and group 3, respectively. Same no significant effect (P <0.05) in the final chest circumference (100.3 \pm 2.3 cm day⁻¹, 95.7 \pm 1.3 cm day⁻¹ and 93.7 \pm 0.9 cm day⁻¹), group 2, group 3 and group control, respectively. In bacterial cultures there was significant difference in UFC mesophilic bacteria (P <0.005). The highest value was in group 3 (4639 \pm 1425), followed by 2 group (3279 \pm 1312) and the control group (1961 \pm 684). What coliforms face identified in animal feces (CFU) were recorded in percentage.

Conclusions: It is concluded that the greatest achievement in the consumption of concentrate was observed in group 2 effects of mangosteen extract and xanthone 9-xanthene® providing greater nutrient intake, important in the physical development of calves when they enter the stage productive. Also with mangosteen extract the xanthone 9-xanthene® stimulates activity against enterobacteria of the gastrointestinal tract that promotes intestinal health of nursing calves

Complementary Veterinary Medicine

P03-003-065

Comparison of Radioimmunoassay and VIDAS methods for progesterone and estradiol determination in dairy cow serum.

Jacek Mrowiec¹, Jan Twardon¹, Agnieszka Antonczyk², Agnieszka Bartoszewicz¹

¹Department of Reproduction and Clinic of Farm Animals, ²Department of Surgery, Wrocław University of Environmental and Life Sciences, Wrocław, Poland

Objectives: Radioimmunoassay method (RIA) is the most important method for measurement of steroid hormones levels. It is easy, cheap, and sensitive but needs special equipment and laboratories to perform because of using radioactive agents. Evaluation of P4 and E2 using VIDAS method is based on enzyme-linked fluorescent assay (ELFA). This method is very easy, rapid, safe, comparable in price with RIA (but equipment is much cheaper and easier to calibrate) and it could be used in field conditions. The aim of this study was to compare RIA and VIDAS methods for P4 and E2 bovine serum concentrations.

Materials and Methods: The study was performed on 38 dairy Holstein-Friesian cows and heifers ranged from 18 months to 9 years of age. All animals included to the study did not show any signs of clinical diseases. Eight animals were pregnant (1 heifer, 7 cows) in different stages of gestation (ranged from 49 days to 6 months). Additionally 6 of them showed oestrus behaviour during pregnancy without any disturbances of gestation.

The blood samples were collected from jugular vein in 10 ml syringe and immediately put to the test-tube. After transport to the laboratory within 2 hours all samples were centrifuged and serum was stored at -80 °C until evaluation was performed (within 4 weeks).

Progesterone and estradiol concentrations in every sample were evaluated using two methods: enzyme-linked fluorescent assay (VIDAS) and radioimmunoassay method (Wizard) to compare results.

Statistical Analysis

The Shapiro-Wilk test was performed to determine whether the data was normally distributed. The non-parametric Wilcoxon matched pairs test was used to assess differences between estrogen and progesterone level results obtained by RIA and VIDAS methods. A Bland-Altman [Bland and Altman 1986] assessment for agreement was calculated to compare the two methods. A range of agreement was defined as mean bias $\pm 2SD$. Correlations were evaluated using the Spearman test. A value of $p < 0.05$ was chosen as the limit for statistical significance.

Results: Mean estrogen concentrations obtained by RIA and VIDAS methods were 5.47 ± 5.20 pg/ml and 12.99 ± 9.47 pg/ml, respectively. Paired Wilcoxon test confirmed significant differences between the two methods in estrogen level results ($p < 0.0001$). Mean progesterone concentration obtained by RIA was also significantly different compared to results obtained by VIDAS ($p < 0.0001$) (table 1). Despite a significant difference between the progesterone level results determined using the two methods, there was a close correlation between the two ($r = 0.973$, $p < 0.0001$) (figure 1).

To further examine whether there was an agreement between hormone level measurement methods, the Bland and Altman [1986] plot of the mean versus the difference of the values obtained from these methods was performed.

Conclusions: Differences between estradiol and progesterone concentrations received in ELFA and RIA methods respectively were statistically significant, so we conclude that enzyme-linked fluorescent

assay is no equivalent to RIA method and it couldn't be considered as reference method.

Complementary Veterinary Medicine

Proteinogram And Serum Biochemistry Of Holstein Cows In The Peripartum Period

Thais G. Rocha¹, Camila Bortoletto¹, Daniela G. Silva¹, Claudia Aparecida S. Nogueira¹, Renata L. Nagib Jorge¹, Paulo Cesar Silva¹, Jose Jurandir Fagliari¹

¹Veterinary Clinic and Surgery, FCAV-Unesp, Jaboticabal, Brazil

Objectives: The aim of the present study was to evaluate the kinetics of proteinogram, enzymatic activities and levels of minerals and lipids in blood samples obtained from primiparous and multiparous Holstein cows in the peripartum period.

Materials and Methods: Blood samples were obtained from 24 primiparous and 24 multiparous Holstein cows by jugular venipuncture using vacuum tubes without anticoagulant in three occasions: 60 days (M60), and 30 days (M30) pre-partum and immediately after parturition (M0). Blood samples were centrifuged at $1,000 \times g$ for 10 minutes, and serum samples were stored at -20 °C until analysis. Electrophoretic separation of serum proteins was carried out in polyacrylamide gels containing sodium dodecyl-sulphate (SDS-PAGE) and biochemical analysis of blood serum was performed by spectrophotometry using commercial reagents. Data obtained were analyzed by ANOVA and differences between groups or moments were compared using Tukey's test, considered significant when $P < 0.05$.

Results: Serum concentrations of total protein, albumin, globulins, magnesium, cholesterol, as well as gamma-glutamyl transferase activity were higher in multiparous cows, while serum levels of ceruloplasmin, total calcium and alkaline phosphatase activity were higher in primiparous cows. The moments influenced concentrations of total protein, globulins, immunoglobulin A, immunoglobulin G and transferrin, which were lower in the day of parturition as compared to the other sampling times by 17%, 25%, 43%, 73%, and 25.5%, respectively, in both groups. Concentrations of ceruloplasmin, and haptoglobin increased an average of 54.4% and 28.9%, respectively, in both groups, also in moment 0. Multiparous cows, when compared to primiparous cows, showed a more pronounced decrease in levels of total calcium (13.8% versus 7.2%), phosphorus (10.9% versus 9.88%), cholesterol (34.8% versus 18.4%) and triglycerides (39.5% versus 30.6%) in the day of parturition.

Conclusions: Based on these findings, it can be concluded that the influence of parity should be taken into consideration when evaluating acute phase protein concentrations, enzymatic activities and mineral and lipid concentrations of high yielding transition cows.

Comments: Authors thank Fundação de Amparo à Pesquisa do Estado de São Paulo (FAPESP) for the financial support and scholarship granted (Processes 2010/02414-1 and 2010/10677-0).

Tibial nerve paresis in post partum German Holstein cows - Etiology and Treatment under farm conditions

Anne Kretschmar; Matthias Kaiser; Alexander Starke

Clinic for Ruminants and Swine, Faculty of Veterinary Medicine, University of Leipzig, Germany

Objectives: Peripheral nerve injuries are the most frequent bovine neurological disorder. Further the tibial nerve paresis is the most frequent cause of lameness in milking cows after parturition in modern husbandry systems beside claw diseases. This abnormality in movement is shown in a hyperflexion of the hock and a forward knuckling of the fetlock joint. The aim of the study is to develop a diagnostic and therapeutical procedure and verify these under farm conditions.

Materials and Methods: In a period from July 2013 to January 2016 in 50 cows the diagnosis of a tibial nerve paresis was made. In 28/50 cases the cows were presented on farm visits and in 22/50 cases the cows were stationary patients in the Clinic for Ruminants and Swine in Leipzig. In 20/50 cases no treatment were made, because in twelve cases the owner didn't want any treatment, in six cases the symptoms were present only for 24 hours and in two cases the cows had to be euthanized in consequence of more severe diseases (coma hepaticum, bilateral pyelonephritis). The other 30 cows were treated in the following way. After initial systemic treatment with antibiotics and steroidal antiphlogistics (each cow received an intravascular injection of 0.4 mg/kg BW dexamethasone) the affected leg was stabilized from the coronary band to the distal aspect of the tarsal joint using a cast made of synthetic resin. The cast was removed after 28 days by splitting it laterally and medially into two parts. These two parts were brought together as a new bandage remained for two more weeks. Then a new supporting bandage for more two weeks was applied in the same dimension. In 14/29 cases this treatment was performed completely in the farms and 16/29 were initially treated in the clinic. In nine of the 16 cases the cows were intensively monitored and controlled based on the project design. This included a stationary stay for one to two weeks, daily clinical examination, laboratory diagnostics and partially the sonographic and electrophysiological examination of the hindlimbs.

Results: In 8/30 cases there was too much pressure on the limb from the cast which resulted in decubitus wounds, mostly presented in severe cases of tibial nerve paresis with a high grade of hyperflexion and knuckling. By changing the treatment schedule in form of removing the cast earlier and treating for a longer time with supporting bandages the paresis could be treated in seven cases. In one case the complications were too severe so the cow was brought to the slaughter house. In each of the 30 cases there were no more signs of a tibial nerve paresis after treatment (usually after 56 days, most often after 28 days).

Conclusions: The short regeneration time in each case shows that a low grade damage of the nerve is present. If there is a severe damage of the nerve with following WALLERIAN-degeneration the regeneration would need a time of two month to one year, depending on the localization of the damage. This study presents an way to treat the tibial nerve paresis in case of a lowgrade nerve damage. There are a lot of reasons for the damage of the tibial nerve in post parturient cows. With increasing the collection of data concerning the preliminary reports in following studies it will be possible to find out the cause and prevent tibial nerve paresis.

Ultrasonographic Anatomy of the Bovine Temporomandibular Joint

Johann Kofler^{1,*}

¹Department of Farm Animals and Veterinary Public Health, Clinic for Ruminants, University of Veterinary Medicine Vienna, Vienna, Austria

Objectives: Reports of temporomandibular joint (TMJ) disorders in cattle are rare. The low incidence may possibly be explained by the difficulty in diagnosing TMJ disease. Clinical symptoms are not specific, feed intake and mastication are impaired, and opening of the mouth is painful. Clinical findings may include swelling, pain, and fluctuation. The TMJ is difficult to physically investigate in cattle presenting with a clinical problem in this area.

Therefore the objectives of this study were to report the normal ultrasonographic appearance of the TMJ in cattle, and to delineate sonopathological findings of the TMJ assessed in two patients.

Materials and Methods: A 7.5 MHz linear and a 6.0 MHz convex transducer (Mindray™ DP 50 Vet, Mindray Medical International Ltd., Shenzhen, China) were used for the TMJ examination in twelve healthy Holstein-Friesian cows with a mean age of 68.9 months, in four cadavers and in two cattle showing clinical signs of TMJ disease. Ultrasonography was carried out in standing cattle with the animals restrained in a crush. Each TMJ (n: 24) was scanned in a rostralateral (RL), lateral (L) and the caudolateral (CL) plane. The distance from the surface of the skin to the zygomatic process of the temporal bone and the distance from the skin to the lateral edge of the condylar process (CP) of the mandible were measured. In addition, the echogenicity and characteristics of the bone surfaces, TMJ space, joint capsule, disc, muscles, adjoining blood vessels and the parotid salivary gland were described.

Ultrasonographic images were compared with the findings of gross anatomical dissection and frozen anatomical sections of this region in four cadavers.

Results: The lateral canthus of the eye, the base of the ear, and the visible zygomatic arch in between served as landmarks for palpation of the TMJ region. The transducer was then placed perpendicularly mid-way between the lateral canthus of the eye and the base of the ear over the zygomatic arch, resulting in the L-plane. The ventral tip of the transducer then remained over the CP of the mandible, while the dorsal tip of the transducer was rotated 45° rostrally to obtain the RL-plane or 45° caudally resulting in the CL-plane. The relevant joint-forming bone surfaces, blood vessels, muscles and the parotid salivary gland could be imaged in all normal TMJ. Using the linear transducer the articular disc could never be visualised, and the joint capsule only in 70.8% via the CL-plane. Using the convex transducer, the TMJ capsule could be imaged in 100% of joints in the CL-plane, and in 54% of cases the lateral parts of the disc could be depicted. It was never possible to differentiate the TMJ pouch in healthy cattle.

In contrary, in two bovine patients a marked anechoic and heterogeneous hypoechoic effusion of the TMJ with distension of the joint capsule could be depicted.

Conclusions: This study describes the ultrasonographic appearance of the TMJ region in healthy cattle for the first time. These results provide reference for ultrasonography of pathologic conditions of the TMJ region in cattle. Since other diagnostic imaging techniques, such as CT or MRI, are not feasible for the majority of bovine patients, the authors would recommend that all bovine veterinarians, who are equipped with at least 7.5 MHz linear rectal probes, should use ultrasonography for further investigation of clinical cases with masticatory problems of unclear origin to exclude or diagnose TMJ disorders.

Ultrasonographic Estimation Of Forward Or Backward Rotation Of The Distal Phalanx Within Cow's Claws

Takeshi Tsuka¹ Ryo Nishimura¹ Mitsugu Hishinuma¹ Yusuke Murahata¹ Kazuo Azuma¹ Tomohiro Osaki¹ Norihito Ito¹ Yoshiharu Okamoto¹ Tomohiro Imagawa¹

¹Tottori University, Tottori, Japan

Objectives: Ultrasonography has been previously applied for measuring sole thickness, and the distance between the sole surface and basal surface of the distal phalanx (S-D distance). However, forward or backward rotation of the distal phalanx has not yet been evaluated quantitatively in previous applications of ultrasonography to the claws. The present report included methodological evaluations to quantitatively estimate forward or backward rotation of the distal phalanx using ultrasonography, to clarify correlations with computed tomographic (CT) measurements (Tsuka et al., J Dairy Sci 2014;97:6271-6285).

Materials and Methods: 267 pairs of hind limbs, which were obtained from lactating Holstein cows in a slaughter-house, were used to be examined using CT (Pronto SE or ECLOS; Hitachi, Tokyo, Japan). 150 of 267 pairs of hind limbs were used to be examined using ultrasonographic machine (HI VISION Preirus; Hitachi-Aloka Medical, Tokyo, Japan: measurement accuracy was 0.1 mm). Slight trimming was applied to all claws before CT and ultrasonographic examinations for purpose of making flat, smooth sole surfaces by improving irregularities, and maintaining original hoof shapes. Sole thickness and S-D distance were measured at 2 points on mid-sagittal 2D CT and ultrasonographic images: point A was located on the virtual line from the most apical margin of the distal phalanx to the sole surface; and point B was located on the virtual line from the most caudal margin of the distal phalanx to the sole surface. Data at point A were subtracted from data at point B (B-A sub). The relative angle of the distal phalanx to the sole surface (S-D angle) was calculated from the angle between the virtual line along the apex to the flexor tuberosity in the distal phalanx and sole surface. Estimation accuracies were investigated using Pearson correlation coefficients between S-D angle and B-A sub of the sole thickness, and between S-D angle and B-A sub of the S-D distance on CT and ultrasonographic images. Correlations between B-A subs of S-D distances and S-D angles on CT and ultrasonographic images were investigated using linear regression analysis. A p value of <0.05 was considered statistically significant.

Results: In applications of ultrasonography to the 600 claws of 150 pairs of hindlimbs, the B-A subs of sole thickness, and S-D distance could be evaluated in 531 claws (88.5 %), and 551 claws (91.8 %), respectively. The Pearson correlation coefficient between S-D angles and B-A subs of sole thickness was significantly high at $r = 0.743$ ($p < 0.05$), and $r = 0.582$ ($p < 0.05$), but tended to be lower than those between S-D angles and B-A subs of S-D distances ($r = 0.783$, and $r = 0.684$; $p < 0.05$) in CT and ultrasonographic measurements, respectively. The linear equations describing the relationship between B-A subs of S-D distance and S-D angles were $y = 0.62x + 2.77$ in ultrasonographic measurements, and $y = 0.83x + 2.15$ in CT measurements, where y represents the S-D angle and x is the B-A sub of the S-D distance obtained from ultrasonographic images.

Conclusions: According to the linear equation describing the relationship between B-A subs of S-D distance obtained from ultrasonographic images and S-D angles, the optimal S-D angle of 3.0° (Tsuka et al.,

2014) is likely acquired by hoof trimming as the S-D distance in the region of the heel becomes approximately 0.4 mm thicker than that in the region of the toe. On the other hand, a critical S-D angle of 6.0° (Tsuka et al., 2014) is related to an S-D distance at the heel >5.2 mm thicker than at the toe on ultrasonographic images.

Comments: Rotations of the distal phalanx forwards or backwards to the sole surface inside the bovine claw are well known as the causative factors of sole horn disorders. However, it has not yet been evaluated quantitatively in previous applications of ultrasonography to the claws, although ultrasonography has been useful for measuring sole thickness, and the distance between the sole surface and basal surface of the distal phalanx. The present study indicates that the rotations of the distal phalanx can be estimated by measuring sole thickness, or the distance between the sole surface and basal surface of the distal phalanx in 2 points of the sole surface. For making the linear equations, a great many specimens have been examined using CT and ultrasonography. We believe that the present data will be very reliable, and very useful for field applications of ultrasonography to bovine claws.

Investigation to local complications after the retrograde intravenous regional anesthesia of the toe of dairy cattle

Hendrik Müller^{1*}, M. Reckardt¹, K. Nechanitzky², A. Steiner², A. Starke¹

¹Clinic for Ruminants and Swine, Faculty of Veterinary Medicine, University of Leipzig, Germany

²Clinic for Ruminants, Vetsuisse-Faculty, University of Bern, Switzerland

Objectives: The retrograde intravenous regional anesthesia (RIVA) is a common technique on the distal bovine limb. There are reports about different complications from clinics in the literature. Aim of the study was to prove the innocuousness of the RIVA under field conditions.

Materials and Methods: The investigation was realized in a freestall barn on 44 German Holstein cows (age: 4.8 ± 1.5 years, bodyweight: 610 ± 73 kg, milk yield: 43 ± 10 kg/day). The cows suffered superficial to perforating lesions of the pododerma (N = 33) on one hind limb or were healthy animals (N = 11). After the shave, cleaning, defatting and disinfection of the injection area we performed a RIVA on one hind limb of every cow (plantar common digital vein IV, N = 37; dorsal common digital vein III, N = 7). The tourniquet leaved 25 min in every case. A bandage below the dewclaws was applied. The injection area was checked clinically and with ultrasonography one, four, six and 24 days after the RIVA.

Results: One day after the injection we detected superficial skin irritations (N = 3) and an increase of the skin thickness without (N = 2) and with acute inflammation signs (N = 1) in the injection area. At that time we found edema of the hypoderm on seven animals during the ultrasonographic examination. Four of these animals were also clinical conspicuous (skin irritation N = 1; increased skin thickness N = 3). Overall we detected nine cows with alterations in the injection area. Six of these animals had a pododermatitis and three were healthy cows. In each case of these animals the injection was performed in the plantar common digital vein IV. Hematoma or thromboses were not diagnosed. All superficial skin irritations recovered three and the increased skin thickness in the injection area not later than six days after their first appearance.

Conclusions: The skin irritations are obviously small irritations in connection with the shave of the injection area. Aspect for that is the location of these lesions in the lateral injection area, which was not protected from the bandage. The edema of the hypoderm could be a sign of a local dermatitis or a partial paravenous application of the local anesthetics. We could not find a negative effect for the healing of the claw dermis lesions. The located complications were mild and recovered without any further therapy. In our opinion the RIVA is an excellent and save anesthesia for the veterinarian practice in the farms.

Methodology for mammary thermography in dairy cows

Gertrud Elisa Campos Edler^{1,2}Valentim A. Gheller²Maristela S. Palhares³Alvaro A. Ribeiro⁴

¹Veterinary Clinic and Surgery - Veterinary Clinic Center, UNIPAM, Patos de Minas, ²Adjunct Professor - Department of Clinics and Surgery, ³Adjunct Professor - Department of Clinics, ⁴Graduate Studentery - Department of Clinics and Surgery, Federal University of Minas Gerais, Belo Horizonte, Brazil

Objectives: The objective of this experiment were determine best methodology for conducting the mammary thermography, in environment of production, in 123 crossbreed dairy cows, that are in lactation peak and high milk production.

Materials and Methods: Animals with problems in clinical examination, other than mastitis were treated and exclude from the study, to avoid ambiguous infrared thermography data.

Thermography pictures were made with the Flyer® thermographer, Thermal resolution is automatically calibrated to ambient temperature.

The pictures was performed 0.5 meters away from the udder, lateral images for fore quarters and caudal and side images for rear quarters. The pictures always followed the same sequence that began right fore quarter, right rear quarters, left rear quarter and finally left fore quarter. The caudal projection described by Pezenshke et al. (2010) was performed to compare with the lateral projection to determine the best field projection for rear quarters.

To avoid mastitis influence on thermographic temperatures, mammary quarters were categorized: No changes (0 milk score in strip cup and SCC (somatic cells count) less than 200 × 10³ cells); b) subclinical mastitis (0 milk score in strip cup and SCC greater than 200 × 10³ cells); c) clinical mastitis (milk score 1 or greater in strip cup).

For evaluation mammary thermography, minimum and maximum temperatures of most uniform area of quarter were tabulated, as described by Schmidt (2008), Hovinen et al. (2008), Polat et al. (2010) Pezenshke et al. (2010). Data was subjected to analysis in the statistical program SAS (2003) and IBM SPSS Statistics 19. Comparison of mean temperatures obtained according to the group (no changes, subclinical mastitis and clinical mastitis) was performed by PROC MIXED option REML

Results: When comparing separately maximum and mean of fore quarters with rear quarters, rear quarters was higher (p <0.05), independent of quarter SCC. It's going against reported by Schmidt (2008) who described fore quarters with higher temperature (0.6 ° C) than rear. It probably did not occur in this study due data use from

lateral projection (minimum, maximum and mean temperatures) for the evaluation of rear quarters, which are protected by medial surface of hind limbs, preventing heat loss to environment. However, when evaluating mammary thermography of rear quarters by caudal projection and fore quarters by lateral projection (DIFTOT), the thermal temperature was similar between each categories (p> 0.05) in different times. Likewise, Poikalainen et al. (2008) report a similar (p> 0.05) between the temperature of the udder surface between fore and rear quarters right or left when working with dairy cows.

However, when evaluating DIFTOT or DIFCENT that using the side projection for rear and fore quarters observed similarity (p> 0, 05) between fore and rear quarters, regardless of subclinical or clinical mastitis.

Conclusions: The temperature difference between maximum and minimum enable correction any distortion caused by mammary quarter position and external factors. Because it will increase the minimum and maximum temperature. In this study there was no statistical difference between use of caudal projection for rear quarters and side projection in fore quarters. The recommendation is use caudal view for evaluation of rear quarters to be agile, easy, practical and better suited to production system.

P02-002-060

A new endoscopic approach for bronchoalveolar lavage - compared with traditional transtracheal lavage for bovine respiratory disease diagnostics

Wolfgang Hasseler¹Franz Schlederer²

¹Veterinär Gemeinschaft, Papenburg, Germany, ²Tierarztpraxis Andorf, Andorf, Austria

Objectives: Bronchoalveolar lavage (BAL) is a very common and useful diagnostic approach for bovine respiratory disease (BRD) management. Traditionally the lavage is carried out through the trachea (trans tracheal lavage – TTL). A new hand held multiscope (endoscope with several different functions; Ivetscope, Quidee, Germany) has been designed for a more convenient way of BAL under field conditions. The aim of this study was to compare two different methods of BAL – the puncture of the trachea with the transtracheal lavage against the oro-laryngeal method.

Materials and Methods: The new endoscope approach was applied on 64 calves (age 2 – 22 weeks) with bovine respiratory disease (BRD) history. Bronchoalveolar liquid was sampled for microbial and virological evaluation. 32 calves were collected by the traditional way (TTL), whereas 32 calves were examined by the use of this new endoscope (BAL). The pistol-shaped, hand-held and cordless endoscope, reaches 40 cm in length, with 2 working tunnels. A camera is positioned next to the corpus, so that a visual adspection can be carried out simultaneously. Calves were sedated (xylazine, 10mg/kg) prior to treatment, kept into sterno-ventral position with the head held manually by the farmer. Each time two samples of broncho-alveolar liquid were collected: From the deeper part of the lung (>50 cm distance) and from the upper part of the bronchus (30-40 cm). They were split equally into a modified New York City medium (NYC medium; Biocheck) and a sterile vessel for further examination.

Results: On average in a total of 15,4% of all cases no agent could be identified. With this new method only in 6,1% (4 times less!) of all cases the responsible microbiological cause could not be identified, whereas

the traditional technique reveals 25% "no agents" ($p < 0.01$).

Single strains of bacteria/virus results were obtained two times more often with the BAL method (60.6% vs. 34.4%) than with the TTL approach.

BRSV was found in total of 9.2% of all analysed samples, with no difference between the two methods.

M. bovis was found three times more often (33.3% vs. 9.4%) with the endoscope lavage (BAL).

P. multocida was the most single prominent bacteria to be found in the lung, in total 9.2%. 15.6 % of all cases monocausal cases are diagnosed with *P. multocida* by TAL vs. 3.0 % by BAL; whereas BAL revealed *P. multocida/M. bovis* 5 times more often than with the TAL method (15.2% vs. 3.1%).

Conclusions: The new BAL method with the Ivetscope seems to result in an obviously more precise identification of relevant respiratory tract bacteria.

M. bovis might be more difficult to collect in traditional TTL and could be overgrown by other bacteria as the mixed infection and contamination rate is significantly higher in TTL sampling.

As the Ivetscope method is also less invasive and more rapid than the TTL method, it offers a more reliable and practical way for BRD diagnostics and herd screenings.

P02-002-061

Assessment of Broad Ligament ultrasonography as a novel technique for endometritis diagnosis in dairy cows.

Tom Lyons ^{1*}

¹Dept Veterinary Medicine, University of Liverpool, Liverpool, United Kingdom

Objectives: The objective of this study was to investigate any possible relationship between the anatomical characteristics of the Broad Ligament, as shown by ultrasound images obtained from dairy cows after calving, and the incidence of endometritis in these same cows. Since ultrasonography is already used by many farm practitioners during cow fertility examinations, extending its use to the diagnosis of endometritis would increase the value of this medium with no extra capital investment for the veterinarian or need for further sampling and laboratory analysis.

Materials and Methods: dairy cows were recruited from six dairy farms, cows and calved heifers that had been calved 9 - 87 days were recruited.

Using a manual vaginal scoop, any vaginal discharge present was noted and graded on the recognised 0-3 scale (Sheldon and Dobson 2004).

A cross-sectional view of the previously pregnant uterine horn 2-4 centimetres anterior to the uterine body was visualised, captured and stored, using a bovine B-mode ultrasound scanner with an 8.5 MHz linear array probe. Similarly, an image of the ipsilateral Broad Ligament ventral to this point was obtained and stored. The ultrasound probe was adjusted to give the greatest degree of Broad Ligament vascular cross-sectional area in each image at the time of examination to produce as consistent a measurement as possible between animals.

The proportion of fluid in the Broad Ligament was determined by delineating the boundaries of the Broad Ligament and setting contrast threshold limits to select the areas within the Broad Ligament that had

a pixel contrast consistent with the echogenicity of fluid. The fluid area was then expressed as a percentage of the area within the boundaries of the Broad Ligament. The three largest vessels in the images of the Broad Ligament were selected and the diameter of each was measured.

Results: The proportion of fluid in the Broad Ligament and the diameters of the three largest lymphatic vessels (vessels 1, 2 and 3) were greater in animals with endometritis compared to controls ($P < 0.001$, $R^2 = 0.34$, 0.22, 0.21 and 0.19 respectively). The mean (\pm SEM) proportion of fluid in the Broad Ligament was $32.0 \pm 1.7\%$ in cows with endometritis and $18.8 \pm 1.2\%$ in cows without endometritis. The mean (\pm SEM) diameters of the three largest vessels in the Broad Ligament of healthy cows were 2.5 ± 0.2 mm, 2.0 ± 0.1 mm, 1.7 ± 0.1 mm but in cows with endometritis the vessels were 1.4 ± 0.3 mm, 0.9 ± 0.1 mm and 0.8 ± 0.2 mm wider respectively.

Conclusions: The Broad Ligament is a novel focus for ultrasonography and specific changes within the images from this structure are indicative of the presence of endometritis. Changes in the fluid content and vascular dimensions can be measured and are a highly significant indicator of the presence of endometritis. Cows with endometritis have almost twice as much Broad Ligament fluid and wider lymphatic vessels than cows without endometritis. Broad Ligament ultrasonography is a cost-effective, non-invasive tool that gives rapid results in the diagnosis of uterine disease and may be able to help determine the location of the infection or inflammation.

Venography In Distal Digits After Intraruminal Oligofructose Administration

Sabrina Freitas ^{1*} Naida Borges ^{1*} Júlio Cardoso ^{1*} Antônio Dionísio Noronha Filho ^{1*} Danilo Ferreira ^{1*} Paulo José Queiroz ^{1*} Luiz Antônio Silva ^{1*}

¹Federal University Of Goias, Goiania, Brazil

Objectives: This study proposed to describe venographic alterations in the pelvic digits of the crossbred (*Bos indicus* X *Bos taurus*) steers after laminitis induced by intraruminal administration of oligofructose.

Materials and Methods: For this study were used seven crossbred (*Bos indicus* X *Bos taurus*) non castrated steers aging 12.6 ± 0.9 months and weighting 156 ± 37.8 kg. The animals were sorted in two groups (GI and GII) receiving 13 and 17 g/kg, respectively, of the oligofructose trough the rumen. Venography of pelvic distal limbs were done in different moments, 36 hours (M1), seven (M2), 15 (M3) and 30 (M4) days after intraruminal administration of oligofructose. With the venography it was intended to evaluate possible changes involving main veins and those observed in coronary corium and bulbar regions of bovine pelvic digits, having M0 as control. The diameters of common digital dorsal vein III, plantar branch to digital cushion and dorsal distal phalanx vein were measured and the values were compared by T test at 5% of significance. The main veins and those from coronary corium, at the different moments, were evaluated descriptively.

Results: Changes in vascularization at different moments were identified, like vasodilation with 36 hours of oligofructose administration and vasoconstriction at other times, in the main veins and at coronary corium and bulbar net. On animals of higher dose of oligofructose changes were more prominent. There were statistical differences for distal dorsal digital vein III between M1 and M4 moments in each group. For GI, the normal diameter of this vein was 0.387 ± 0.023 cm, in M1 was 0.479 ± 0.103 cm and in M4 0.378 ± 0.063 cm. For GII, the

normal diameter for distal dorsal digital vein III was 0.406 ± 0.084 cm, in M1 0.445 ± 0.085 cm and in M4 0.341 ± 0.029 cm. Therefore, there was vasodilation in M1 and vasoconstriction in M4. To the plantar branch of digital cushion of medial digit there was difference between groups at M4, with more vasoconstriction in GII (0.087 ± 0.079 cm) comparing to GI (0.195 ± 0.032 cm).

Conclusions: It could be concluded that venographic examination of the pelvic digits of the crossbred (*Bos indicus* vs *Bos Taurus*) steers, after intraruminal administration of oligofructose, permits the description of the local vascular anatomy and the identification of changes compatible to laminitis.

Biometry Eye Measurements by Ultrasonography in Jersey Breed Cattle: Preliminary Study

Carla Neves¹Naida Borges¹Leandro Arévalo¹Aline Maria Lima¹Júlio Cardoso¹Luiz Antônio Silva¹

¹Federal University of Goias, Goiania, Brazil

Objectives: The aim of this study was determining the normal measurements of the eye chambers of the bovine Jersey breed and describe the features of the eyes, by B-mode ultrasonography, to provide normal references values.

Materials and Methods: The ocular biometry was done in 40 healthy Jersey breed cattle aging between 3-36 months. The young animals were contained manually and adults in the chute. The head should be restrained by two assistants to facilitate the centralization of ocular bulb and minimize any sudden movements. Ultrasound examination of each animal was performed using linear transducer selected in 12 MHz (GE Logic Healthcare®) after topical anesthetic eye drop administration. The sterile acoustic gel was used and the ultrasonographic examination was performed without pressing the transducer against the ocular surface. A single investigator executed all ultrasound examinations. The measurements in the right and left eyes were taken in vertical axial section and horizontal axial section. In the both sections the axial length (AL - distance from the epithelial layer of the cornea to the posterior wall of the eyeocular bulball), the anterior chamber depth (AC - from the Descemet's membrane to the anterior lenticular capsule), the lens thickness (LT - distance between the anterior to the posterior lenticular capsule) and the vitreous chamber depth (VC - distance between the posterior lenticular capsule to the back wall of the ocular fundus) were measured. The means and standard deviation of measurements for the right and left eyes were presented. The means were compared by t test with 5% level of significance.

Results: The cornea was identified as two parallel but convex hyperechoic lines, separated by a thin anechoic line. The lens appeared as two hyperechoic lines, and a convex (anterior capsule) and a concave (posterior capsule) separated by anechoic content. Adjacent to the anterior lens capsule was observed the iris and the ciliary body, both with hypoechoic appearances. The ciliary body is thicker and irregular when compared to other domestic species. The vitreous chamber and the anterior and posterior chambers appeared as an anechoic region. The back wall of the eye was seen as a regular and concave hyperechoic line. Means and standard deviations of the AL, AC, LT and VC observed in the horizontal axial section, to the left vs right eyes, were as follows: (3.07 ± 0.17 vs 3.08 ± 0.17 , $P = 0.99$), (0.49 ± 0.04 vs 0.50 ± 0.04 , $P = 0.87$), (0.98 ± 0.07 vs 0.98 ± 0.07 , $P = 0.99$) and (1.53 ± 0.08 vs $1.54 \pm$

0.07 , $P = 0.74$). For vertical axial section, were found, respectively: (3.07 ± 0.18 vs 3.08 ± 0.18 , $P = 0.97$), (0.49 ± 0.05 vs 0.49 ± 0.05 , $P = 0.92$), (0.98 ± 0.07 vs 0.98 ± 0.07 , $P = 0.82$) and (1.53 ± 0.07 vs 1.54 ± 0.07 , $P = 0.99$).

Conclusions: The dimensions of the right and left eyes are equivalent by ultrasonography biometry. The mode-B ultrasonography is a quick, minimally invasive and safe method which resulted in important information about the intraocular dimensions, making it possible to standardize the eye measurements of specific breeds in different age groups. These results could be useful for diagnosis of diseases that change the size of the chambers of the eye.

Validation of an easy-to-use device for non esterified fatty acids (NEFA) assay in blood in dairy cattle

Louise Gros¹Lucile Peuch²Christian Engel³Jantijn Swinkels⁴Pierre-Hugues Pitel⁵René Fournier⁶Sylvie Chastant-Maillard¹

¹UMR INRA/ENVIT, Toulouse, France, ²Reproduction, UMR INRA/ENVIT, Toulouse, ³Clinique vétérinaire de la Rance, Broons, France, ⁴MSD Animal Health, Boxmeer, Netherlands, ⁵LABEO Franck Duncombe, Caen, ⁶MSD Animal Health, Beaucouzé, France

Objectives: The presence of non esterified fatty acids (NEFA) in blood is an indicator of lipolysis and are thus interesting markers of negative energy balance of post partum dairy cows. NEFA seem more reliable indicators than beta hydroxybutyrate, widely assayed by vet practitioners thanks to the availability of portable cow-side devices. The main limiting factor for NEFA assay in practice is the requirement of an appropriately equipped laboratory. The aim of this study was thus to validate NEFA assay results obtained through a spectrophotometer in field conditions, i.e; of easy use at the veterinary clinic.

Materials and Methods: Blood (5 ml) was collected on dry tubes from the coccygeal vein from 2 weeks before and 2 weeks after calving in 100 cows from 6 herds. Blood was stored at -4°C until centrifugation, and serum separated into two aliquots frozen at -20°C until analysis.

One aliquot was assayed by spectrophotometry at the veterinary clinic (Vetphotometer Diaglobal GmbH, Berlin, Germany) following the manufacturer's instructions. Measurement range indicated by the manufacturer goes from 0.02 to 4 mmol/L.

The second aliquot was analysed by automated colorimetry (RANDOX kit, London, UK), considered as the reference method. Measurement range goes from 0.04 to 2 mmol/L. Intra and inter assay coefficients of variation are below 5%.

Correlation between the results obtained by the two methods was evaluated by a Spearman test with $p < 0.05$ considered as statistically significant.

Results: Intra and inter assay coefficients of variation for the tested spectrophotometry method were respectively 4.3% and 9.6%. Correlation between values obtained by the spectrometer and the reference method is high, with a Spearman's coefficient of 0.96 ($p < 0.001$). Both values were linked by the following equation: $[\text{NEFA}]_{\text{photometer}} = 0.581 [\text{NEFA}]_{\text{reference}} - 0.0018$. The commonly used threshold for NEFA blood concentration defining negative energy balance by the reference method is 0.3 mmol/L (Ospina et al 2010; Chapinal et al, 2011) to 0.5 mmol/L (Leblanc et al 2005) when assayed 2-14 days before calving. After

calving, the threshold value changes to 0.72 mmol/L with the reference method (Ospina et al 2010). These thresholds for the spectrophotometer can be calculated thanks to the equation to respectively 0.17 to 0.29 mmol/l before calving and 0.41 mmol/l after calving.

Conclusions: Measuring NEFA concentration in blood of dairy cows with the spectrophotometer is reliable, simple, quick (results in 20 minutes) method and does not require any specific equipment (except the photometer). The spectrophotometer is thus an appropriate tool in practice for energy balance monitoring of dairy cows during the transition period.

The use of thermography to measure ocular temperature and its correlation with rectal temperature in cattle

Gabriela A. Reis¹Milton Ricardo Azedo^{2*}Juliana A. Bomberdelli¹Caroline H. Seino¹Carolina D. L. Shecaira¹Fernando J. Benesi¹

¹Departament of Medical Clinics, School of Veterinary Medicine and Animal Science, São Paulo, ²School of Veterinary Medicine, Metropolitan University of Santos, Santos, Brazil

Objectives: This study aimed to correlate the temperature of the ocular region recorded by the infrared camera and rectal temperature measured using digital thermometer in healthy calves. Infrared thermography is a modern method, non-invasive and safe to perform a thermal profile. With wide application in human medicine for diagnostic purposes, in veterinary medicine its use is still restricted. In cattle, a key advantage is it does not require direct physical contact with the animal, which would facilitate and expedite the diagnosis of various diseases

Materials and Methods: Thirteen holstein calves, healthy and up to thirty days old were used. The animals were housed within the Cattle Hospital and Small Ruminants FMVZ - USP, in covered and out of direct incidence of sunlight and wind location, taking care to achieve a reliable infrared thermography image, avoiding dirt and moisture in the animal's hair coats, considering the effect of circadian rhythm (the data were collected at the same time), the time after eating, exercise and pre-existing skin lesions. Through a thermographic camera, with colorful palette, images of ocular region was collected and concomitant rectal temperature was measured using a digital thermometer. During the analysis the animals were maintained on station. Eighty-nine data collection were performed and subsequently analyzed by a specific software. Thermal information of each pixel has been processed thus generating the maximum temperature point of the particular area. Therefore, an orbital image was obtained by drawing an oval image including the eyeball. The mean, standard deviation and Pearson correlation coefficient was verified.

Results: Based on the ratio of the results of rectal temperature and temperature of the ocular region, were obtained for the rectal temperature the mean and standard deviation of 39.09 ± 0.53 °C and the temperature of the ocular region obtained through the thermograph of 38.67 ± 0.72 °C. For the Pearson correlation coefficient (r) the value found was 0.58, making it possible to affirm that it is positive and medium. The temperature of the eye region obtained by the thermal imager was an average of 0.42 °C lower than the rectal temperature.

Conclusions: Although the infrared thermography camera is good accuracy tool for determining the temperature of any object in addition to the convenience of its use, enabling the verifying changes in temperature

without direct contact with the animal in this study proved not to be of great value in the accurate check of the parameter in question. Indeed, there needs to be more research and development of standard operating procedures for the use of thermographic camera for this technique to be used reliably.

P02-002-066

Use of infrared thermography for the observation of blood vessels at the outer ear of calves

Carolina De Lara Shecaira¹Juliana A. Bombardelli¹Gabriela Alves Reis¹Caroline H. Seino¹Milton R. Azedo¹Fernando J. Benesi¹

¹Faculdade de Medicina Veterinária e Zootecnia da Universidade de São Paulo, São Paulo, Brazil

Objectives: The thermographic examination is conceptualized as the image obtained through an infrared camera, which detects accurate temperature differences, by means of color variations in a thermogram. Through the assumption that the temperature detected by the camera on the skin surface is related to the blood flow and local metabolism, the aim of this study was to collect pictures of calves' outer ears using a thermal camera (FLIR T620) with a black and white output in order to identify the blood vessels of the region.

Materials and Methods: Through a thermal camera (FLIR T620) with black and white output, images were taken at the outer ear of five black and white Holstein healthy calves. The animals were housed at the Cattle and Small Ruminants Hospital - FMVZ in a covered area, without direct incidence of sunlight and weather. All images were carefully taken to achieve a reliable thermal image, avoiding dirt and moisture at the skin, considering circadian rhythm's effects, if animals had been fed or exercised, the application of topical medications and pre existing scars or lesions.

Results: With images taken with the thermal camera (FLIR T620) at the outer ear is possible to visualize, in a grey scale, the vessels conformation of auricular region in contrast to the cartilage. The blood vessels were visualized in a whitish color, corresponding to a higher temperature area, while the external ear cartilage was visualized in a grayish color, corresponding to a lower temperature area. It can also be seen at the vessels images that there is color homogeneity, demonstrating its integrity and suggesting a fully functional organ.

Conclusions: The study demonstrates that thermography is a reliable method to visualize the blood vessels of the outer ear of calves, as well as its integrity and any possible vascular changes. Moreover, it is a noninvasive method, which allows the examination at a short distance from the animal, which is very important when dealing with cattle. The use of thermal imaging is relatively new in veterinary medicine, however it has shown very good results and it could be widely used as a possible diagnostic method and in assistance to veterinary practice.

P02-002-067

Sonographic evaluation of the involution of umbilical cord components in Holstein calves during the first month of life

Juliana A. Bombardelli ¹Gabriela Alves Reis ¹Caroline H. Seino ¹Carolina de Lara Shecaira ¹Milton R. Azedo ¹Fernando J. Benesi ¹

¹Faculdade de Medicina Veterinária e Zootecnia da Universidade de São Paulo, São Paulo, Brazil

Objectives: The purpose of this study was to evaluate the physiological involution of umbilical components of healthy calves by means of ultrasonography, considering the use of 2% or 5% iodine tincture, used in navel treatment during the first days after birth.

Materials and Methods: Evaluation was performed by ultrasonography of intra and extra-abdominal umbilical components in nine different positions, distributed between the xiphoid cartilage and pelvis, following the paths of the intra-abdominal umbilical components. They were characterized regarding the appearance of the images, the measures of the diameter and thickness of vascular structures and urachus, as well as the peculiarities from the two types of disinfecting. Twenty-three Holstein male calves, reared in dairy property located in the State of Sao Paulo, Brazil, were evaluated from birth to 30 days old and for the examinations, the animals were kept in right lateral decubitus.

Results: Commonly found in calves, diseases of the umbilical components can lead to serious complications. Diagnosis of umbilical diseases is often not fully enlightened by bimanual abdominal palpation, since this semiotic method is not sensitive enough to determine the extent of involvement of the intra-abdominal umbilical structures in part of the cases. Thus, ultrasonography is a valuable complementary test for establishing an accurate diagnosis on the location and extent of intra-abdominal omphalitis. Our results showed that the vein and umbilical arteries lose their blood vessels characteristics, assuming a ligament aspect due to fibrous tissue proliferation. This process followed a pattern, in which the fibrous tissue was initially present in the inner part of the vessel wall, heading toward the center of the vessel lumen as the involution evolved. This process of involution was earlier in the parts of the blood vessels that were farthest from the external navel, with no particular differences with the use of different antiseptic concentrations. Measurements of the diameter of the umbilical components and the thickness of their walls were also standardized during their physiological involution. We also observed that, before the decrease of these measures, there was an increase in the diameter of these structures and the thickness of their walls. As these changes occurred between the 15th and the 20th days after birth, ultrasound observations confirmed that this period corresponds to the time when the vessels are losing their features and turning into a ligament.

Conclusions: Our results confirm the accuracy of ultrasonography for the assessment of intra-abdominal umbilical components during the first 30 days of life the calf and establish references to improve the diagnosis and the choice of treatment of umbilical diseases.

Radiographic examination of Epiphysitis in fattening bulls and corresponding pathological aspects.

Enrico Fiore ¹Massimo Morgante ¹Marilena Bolcato ²Matteo Giancesella ¹Cinzia Benazzi ³Michela Levi ³Sonia Giambelluca ¹Andrea Beltrame ³Arcangelo Gentile ³

¹Department of Animal Medicine, Productions and Health, University of Padua, Legnaro, ²Department of Veterinary Medical Science, University of Bologna, Ozzano Emilia, ³Department of Veterinary Medical Science, University of Bologna, Ozzano dell'Emilia, Italy

Objectives: Epiphysitis is an inflammation of the growth plate frequently detected in young beef cattle at the level of the distal metaphyses in the metatarsophalangeal joint.

In literature, this pathological process is associated with rapid growing and high weight increase, traumatic injuries, inadequate environmental conditions, toxicosis, excess or deficiency in diet, hereditary or genetic causes.

The early diagnosis of this disease is still not easy and new detection methods must be studied to identify epiphysitis. The purpose of this study is to identify and differentiate the grades of epiphysitis through the use of X-ray images.

Materials and Methods: This study carried out radiological and pathological findings performed on 54 legs in young bulls. Twenty-eight young fattening bulls from 3 different farms were included in the study (10 Aubrac breed; 10 Limousine breed; 8 Charolaise breed). The average age was 19±4 months and the body weight mean values were 480±65 kg. All the animals were bred 8 per box on hard slatted floor.

Animals treated with antibiotic and/or antinflammatory medication were not included.

On clinical examination the animals presented a second degree of lameness, swelling of the metatarsophalangeal joint which was not painful or warm, no limb hypertermia, rapid weight loss, difficulty in keeping the standing position.

X-Ray of the limbs were performed for all the animals, both for the clinically normal and lame. The bulls were sedated with Xilazine 0.25 mg/Kg IM.

The radiographic examination was performed at the level of the distal metaphyses in the metatarsophalangeal joint using a portable X-ray unit AJEX Meditec® (140 H).

The growth plate lesions were measured with an imaging software (Carestream®Image Suite 3.02.0.141).

The total metric survey of the epiphysis (Total S), three metric surveys on the medial part of the epiphysis (S1-M, S2-M, S3-M) and three metric surveys on the lateral part of the epiphysis (S1-L; S2-L; S3-L) were measured in the images considering the sub-axial line of the metatarsus perpendicular to the metatarsophalangeal joint.

Post-mortem pathological analysis were performed for all the animals.

The data collected were statistically analyzed with SAS 9.3.

Results: The radiographic and the pathological findings of 54 young bulls limbs showed lesions on the growth plate and the area of the epiphysis in 44 cases, although 10 limbs did not show any alterations.

The growth plate lesions presented 4 grades of epiphysis inflammation. The radiographic changes in the growth plate thickness were the following:

- Grade 0 (G0): No growth plate lesions (10 limbs);
- Grade 1 (G1): Growth plate slightly broadened (11 limbs);
- Grade 2 (G2): Multifocal lesions thickening of the growth plate (11 limbs);
- Grade 3 (G3): Partial thickening of the growth plate. Partial degeneration of the bone tissue with wide margins,

large and irregular epiphysis (11 limbs);

Grade 4 (G4): Severe thickening of the total area of the growth plate.
Very irregular broad and wide growth plates (11 limbs).

These lesions were confirmed comparing the radiographs with the gross pathological aspects of the lesions.

Statistically significant differences ($P < 0.001$) were found in total metric mean values (\pm St. Dev) survey on every stages of epiphysitis (G0 < 1mm; G1 = 5.9 \pm 2.4mm; G2 = 8.5 \pm 1.2mm; G3 = 11.4 \pm 1.05mm; G4 = 14.7 \pm 2.7 mm).

No statistically significant differences were found only for G2 in S1-M versus G1, S2-M, S3M, S1-L versus G3.

Conclusions: In conclusion, our findings on the metric radiographic examination showed that it is possible to distinguish four grades of epiphysitis measuring alterations in the growth plate.

The different grades of epiphysitis had different metric features associated with pathological changes in the growth plate.

The only lesions of epiphysitis indistinguishable in some cases using radiographic metric measures were the G2 from G3. This is due to the presence of multifocal lesions diffuse (G2), not always found in the same location and with variable size in the growth plate.

volume observed in the inspection of the ventral cervical region and the rise of palpable volume in the oropharynx besides the presence of pustular formations and moving deficit epiglottis. In subsequent tests, it was shown that the occurrence of dorsal displacement was intermittent and is not present at all times of the examinations. The conservative treatment of the disease with dexamethasone (20 mg) for three days was successful and was not necessary surgery.

Conclusions: Through the results it was possible to confirm the diagnosis of intermittent dorsal displacement of the soft palate and confirm this case as the first description of this disease in cattle in Brazil and the third case report described in the literature.

Intermittent dorsal displacement of the soft palate in cattle

Rodrigo Souza ^{1,7} Arnaldo Souza ¹ Camila Batista ¹ Fabio Pogliani ¹
¹Stéfano Hagen ¹ Alice Della Libera ¹

¹University of São Paulo, São Paulo, Brazil

Objectives: The objective of this case report is to show that non-routine exams in buiatrics clinic (respiratory system), like endoscopy, can be used to assist the diagnosis of respiratory disease in an adult bovine.

Materials and Methods: An adult cow was referred to the clinic Cattle and Small Ruminants Veterinary Hospital of the Faculty of Veterinary Medicine and Animal Science of the University of São Paulo, with history of cough always when ruminated and progressive loss of weight for about two months. Pulmonary auscultation revealed the presence of pathological noises characterized by bilateral dry rales (wheezing), without changing the respiratory tract (costo-abdominal), increased respiratory rate and the presence of thrills compatible with the occurrence of dyspnoea. With use of open mouths internal inspection was conducted to assess possible changes determined by the increase of cervical volume, being observed changes of dimensions in the oropharynx. By direct palpation the region was examined revealing soft consistency in epiglottis, suggesting sagging structure, but without noticeable relative change to its size. After clinical examination and change in finding epiglottis, there was the indication for rinolaringotracheobroncoscopic examination to assess the anterior and posterior airway. For this procedure the animal was restrained and sedated with xylazine (0.2 mg / kg) and anesthetized locally with spray lidocaine in the nasal cavities to pass of the flexible videogastrosopic apparatus (Fujinon EC250LP5) 11.0 millimeters in diameter and 1.60 meters long.

Results: During endoscopic examination, the animal had yellowish mucous and congested blood vessels throughout the length of the airways, swelling in the oropharynx, compatible with the increase in

The Use Of Photovoice To Assess Livestock Health Needs Of Maasai Pastoralists.

Frank Van Der Meer^{1,2*} Eoin Clancy¹ Adam Thomas² Susan Kutz¹ Jennifer Hatfield² Karin Orsel^{2,3}

¹Ecosystem and Public Health, University of Calgary Veterinary Medicine, ²Community Health Sciences, Cummings School of Medicine, University of Calgary, ³Production Animal Health, University of Calgary Veterinary Medicine, Calgary, Canada

Objectives: The Ngorongoro Conservation Area (NCA) in Tanzania is the homeland of Maasai. Maasai are pastoralistic livestock keepers who depend on their cattle, goat and sheep as sources of income and food. Pastoral livestock production can be significantly improved by addressing the veterinary needs of livestock owners. We initiated a needs assessment using photovoice. Photovoice leads to an enhanced understanding of community assets and needs, and to empowerment and motivation of the participants. The objective was to use photovoice to (i) build relationships with the NCA community and (ii) strengthen our understanding of their animal health needs.

Materials and Methods: The photovoice methodology was adjusted to the NCA setting; participants used digital cameras, interviews were performed using a laptop to display all the pictures taken by the participant for discussion.

The photovoice method consists of several phases: (i) identification of participants, (ii) pre-interview and training in the use of cameras, photography technique and asking consent of subject, (iii) photography period, (iv) larger or smaller group discussions, and (v) data analysis. Participants gave informed consent for the pre-photovoice interview and debrief separately.

An initial interview was performed to understand the perspectives of Maasai on animal health and their relation to animals as well as to introduce the topics for the photography part of the project. All participants were asked the following questions:

1. What are animals to the Maasai, and why are they important?
2. How are animals important for human health?
3. What is important to keep animals healthy?

Equipped with an automatic digital camera, participants were directed to take pictures that best represented animal health over the next 7 days.

After having discussed all the photos in a debrief, participants were requested to select the 10 pictures that best represented their story. In the final step, the participants were invited to reflect on the photovoice process and make a comparison with the regular interview (pre-photovoice).

Results: The number of photos taken ranged from 28 to 597. All photos were discussed, and only one participant was asked to identify the 40 most important photos. Each recording of the debrief sessions was transcribed and read by two researchers. Key words were identified and clustered in three major themes: animals, human health, and social topics. The answers to the interview questions were compared to the outcomes of the post-photovoice debrief.

Discussions arising from the pre-photovoice interview questions covered a broad range of topics directly or indirectly related to animals. Key themes and topics that emerged from the post-photovoice debrief were more extensive and detailed compared to the pre-photovoice interview. Topics discussed were: Nutrition, husbandry, availability of water, vaccination, diseases and antiparasitic treatment. The role of cattle in cultural and social aspects of the Maasai society as well as human

health themes were also extensively discussed.

Results from this project were brought back to the communities through workshop style community presentations. In response to the concerns about East Coast Fever, bloat and gastrointestinal parasitism identified during the photovoice project, we developed and delivered workshops on the cause, signs, economics, and treatment of these diseases. Additionally in collaboration with animal health workers and local veterinary staff visual information material was developed and distributed to facilitate these workshops. More than 15 workshops were delivered in different regions of the NCA between 2013–2015.

Conclusions: Photovoice provided the researchers with a community generated list of concerns and priorities to improve livestock health and production. It resulted in an expanded breadth and depth of discussions and knowledge transfer, and participants indicated that they found it an empowering process. In addition, the outcomes directly informed us about research and outreach needs and critically re-enforced the importance of a One Health approach. The use of photography provided a new medium for Maasai to express their needs and a focus for researcher–participant communications, thereby facilitating new insights across language and cultural barriers.

Education

P01-001-002

Use of virtual and augmented reality in veterinary education and extension

Stuart Barber^{1*} Evan Hallein¹

¹Faculty of Veterinary Science, University of Melbourne, University of Melbourne, VIC, 3010, Australia

Objectives: Virtual reality is defined as an artificial world created using computer generated sights and sounds that allow a user to interact with it. Augmented reality is defined as an enhanced version of reality where the user can overlay digital imagery on the real world using something being viewed through a device, such as a smart phone camera. These techniques have significant potential to enhance veterinary education and extension as both image collection and viewing becomes simpler and cheaper. This presentation covers development of virtual and augmented reality resources for veterinary education.

Materials and Methods: Virtual reality described in this presentation encompasses two separate methods of image collection. The first of these has been described in developing the 4D virtual farm in Australasia. This involves the use of a high quality digital SLR camera with fisheye lens to take six images every 60 degrees on a tripod and a further image taken upwards. These images are then be stitched together to produce a 360 degree image using KR pano. This image can then be placed on a farm map and multiple images taken through time to give the fourth dimension of time. Images were collected in West Australia, Queensland, New South Wales, Victoria and New Zealand with assistance from local veterinary school staff. In addition, 360 video footage is collected using a combination of 6 GoPro cameras connected to a 360 heros 360H6 holder. This is then processed using Videostitch software to provide 360 video content. Augmented reality was produced using the Aurasma application, selecting a relevant trigger image and a relevant video or link applied to this image.

Results: This project commenced as a way to bring the farm back to the “classroom” or space where a student wished to preview and review relevant material. Equally it has been developed to bring the classroom

to a property to aid self-directed learning. It is possible to view the virtual reality experience in equipment such as Oculus Rift or Google Cardboard and it is platform independent so works on any Apple or PC system, including mobile systems. Veterinary students across Australasia are starting to use the 4D farms module in 2016 as a purpose built glossary is completed to work with the 4D farms module. The collaboration of five Australasian veterinary schools allowed the capture of images from a broad latitude and longitude in tropical and temperate environments to illustrate a variety of animal health and production issues. Utilisation of individual 360 degree photographs combined with 360 degree timelapse and 360 degree video allows for a wide range of flexibility in presenting relevant material to students.

Conclusions: Where virtual and augmented reality are designed to aid understanding of specific learning objectives they have great potential to help learners understand what happens in distant environments. This includes bringing the classroom to the farm or the farm to the classroom. As equipment for collecting these images becomes easier to use and cheaper along with cheaper equipment to view these images it is likely that both virtual and augmented reality will become far more utilised in both teaching and extension work in veterinary science.

P01-001-003

Perceived barriers and motivators of UK clinicians and academics towards a national examination in farm animal medicine and surgery

Fay Pooley¹; John Remnant²; Wendela Wapenaar²

¹Scarsdale Vet Group, Derby, ²University of Nottingham, Sutton Bonington, United Kingdom

Objectives: Although veterinary schools in the UK are subject to RCVS accreditation, there is currently no unified assessment between veterinary schools in the UK. With more veterinary schools emerging, it is timely to investigate the feasibility of a 'national exam'. The aim of this study was to gather opinions from relevant stakeholders in UK veterinary schools on the feasibility of developing and conducting a national exam in the area for farm animal medicine and surgery.

Materials and Methods: The study was carried out by interviewing one farm academic clinician involved in final year assessment ('clinician') and one other academic who was involved with the final year examination regulations and processes within each veterinary school ('academic'). Semi-structured interviews were carried out allowing the interviewees to expand on their answers and the interviewer to be flexible in the interview process. The interviews were recorded, transcribed and data analysis was performed using thematic analysis (NVivo 10).

Results: Telephone interviews were conducted with 16 participants lasting an average of 30 minutes, with a range from 17 to 44 minutes. Interviewees reported a large variation in the way the eight veterinary schools examined students in the final year of the course. Interviewees commented that getting all of the stakeholders to agree on a common target outcome would be challenging, not insurmountable, but certainly a significant challenge.

Preliminary analysis demonstrated a marked difference between opinions of clinicians and academics. Clinicians appeared more idealistic and in favour of the suggested national exam compared to academics who primarily considered the logistics and execution and shared concerns with regards to this process.

Conclusions: High quality final year assessments are important to veterinary students, universities and the veterinary profession employing new graduates. Assessments take up significant time and a concerted effort between veterinary schools could improve efficiency. This presentation aims to present the barriers and motivators from relevant stakeholders towards a national exam and provide considerations with regards to the feasibility of such an examination.

P01-001-004

The application of a dairy herd simulation model to teach Dairy Herd Health Management

Sergio Calsamiglia¹ and Universitat Autònoma de Barcelona

¹Servei de Nutrició i Benestar Animal, Universitat Autònoma de Barcelona, Bellaterra-08193, Spain

Objectives: Teaching dairy herd health management to animal science or veterinary students is complex because it requires the integration of many areas of knowledge (nutrition, genetics, management, diseases, heifer growth, economics,...). In most cases, students have already been exposed to these areas in previous classes. The challenge is to develop education strategies that allow students to learn the integration of all these areas, and to develop comprehensive decision-making abilities. The objective is to present the use of a dairy farm simulation model used to teach a Dairy Herd Health Management class to last year Veterinary students.

Materials and Methods: A stochastic model that simulates physiological events of heifers, lactating and dry cows (biological model for each group) was developed. For each animal, sub models are developed for feeding, diseases, environmental factors, facilities, management, reproductive management, and economics. All these factors follow established equations that account for the complex interactions among them. Default values for variables are provided, but the student can change them. The conditions established are simulated on an animal-by-animal and day-by-day basis. Students work in groups of 3 and generate a farm (typically a 300 milking cow) under specific conditions. Students are provided with a set of different questions (Is fixed-time insemination programs appropriate? Is a short dry period profitable? Is feeding in two groups profitable? What is the effect of reducing by half the incidence of a specific disease?,...). The outcome provides a list of technical and economic indicators essential for the decision-making process, including demographics, production, reproduction, heifers, diseases and economics. Student use the results to answer the question and have to develop a comprehensive strategy (specific recommendations) to improve the profitability of the farm.

Results: While the case-approach is an excellent tool for integrating concepts and developing decision-making abilities, it is often difficult to generate sufficient cases for large classrooms and for different years. The use of computer-generated virtual farms is an alternative tool to expose students to an endless set of scenarios where they can analyze the condition of a farm, propose alternatives, and simulate the technical and economical consequences of their actions. The process is based on self-learning activities and requires the consultation of scientific references to take proper decisions. The analysis of results helps them to relate the technical with the economical outcome. At the end of the semester, students present a set of priorities that need to be implemented in their farm to the rest of the class and a debate is generated.

The implementation of this strategy has eliminated traditional classes

that have been substituted by debates. After a survey at the end of the semester, student satisfaction was very high (overall evaluation of 4.9/5.0 in a 32 student class). Students appreciate the suitability of the method to integrate concepts, and the feeling of "ownership and professional responsibility" with their own farm was highly motivating. The understanding of the economic implications of the different technical decisions was greatly appreciated. The program is currently available at www.dairyfarm.es/simulador. For the generation of a specific class, contact sergio.calsamiglia@uab.es.

Conclusions: The use of the web-based computer model offers a powerful tool to teach Dairy Herd Health Management. The model helps students to learn the integration of the different areas of a dairy farm, and to develop comprehensive decision-making abilities. Students take responsibility in the decision-making process of a dairy farm and evaluate the consequences of the decision taken. The implementation of this educational strategy has been very well received by students.

Innovative approaches to teaching farm animal clinical skills to veterinary undergraduates

Sarah Baillie¹David C. Barrett^{1*}

¹School of Veterinary Sciences, University of Bristol, Bristol, United Kingdom

Objectives: The Bristol School of Veterinary Sciences has recently undergone a major curriculum review. The initiative has included identifying ways to improve the teaching of clinical skills. The work has involved:

- Development of innovative models
- Design of comprehensive supporting learning resources
- Integration of clinical skills teaching throughout the curriculum

Part of the project focussed on the skills used by farm animal veterinarians and the practical and clinical competences expected of graduates entering mixed or farm animal practice.

Materials and Methods: A series of steps were undertaken including identifying a list of farm animal clinical skills, developing teaching and learning resources, and introducing the new initiatives into the curriculum.

The range of practical and clinical skills required of farm animal veterinarians was reviewed through staff and student discussions, reference to the RCVS Day One Competences and equivalent lists, and posting in discussion threads in an online forum (the 'Veterinary Clinical Skills & Simulation' group in NOVICE www.noviceproject.eu).

Opportunities were identified within the curriculum to complement existing farm animal teaching using models in the newly established clinical skills laboratory (CSL). Factors to consider included the challenges learning the skill for the first time on a live animal e.g. internal examinations such as rectal palpation are a 'black box' for teaching and learning (tutors can't watch or give feedback on performance) and whether use of models would help promote student learning. Additionally if a model was to be adopted in teaching, it needed to be realistic enough but value for money, affordable and preferably reusable.

Some models were available commercially while others were developed in-house using materials from a variety of sources including Smooth-Silicon (used for making masks for the movie industry) which proved

readily adaptable to simulate different types of tissue e.g. to practise suturing. Supporting learning resources included a detailed instruction (skill) booklet for each model.

Results: The CSL contains models that help students learn farm animal practical and clinical skills ranging from applying a halter, to taking blood samples, to performing surgical procedures and enhance students' preparation for work-placements on farms, in veterinary practices and in clinical rotations.

Examples of models developed by the CSL team include for ovine skills - 'Mabel' the life-size sheep (to practice turning her over) and 'Alex' a fully articulating lamb (correct malpresentations prior to delivery); bovine skills - including suturing skin, muscle and uterus (each layer fixed to a frame at cow height) to represent a caesarean or displaced abomasum flank laparotomy, intramuscular and intravenous injection and venepuncture; and porcine - piglet handling, application of a snare and jugular venepuncture. There is also a set of 'car boot to cow side' scenarios which allow students to practise selecting equipment and drugs to carry to the patient (without taking the 'kitchen sink' or forgetting something). A booklet at every station describes (in photos and written text) each step to perform a skill, the equipment required, how to reset the station (in readiness for the next student) and some tips from recent graduates (I wish I'd known...). Another approach has involved using commercial bovine rectal palpation models (physical and virtual) as part of a half day practical when students rotate from CSL to PM room (uterine tracts) to the farm to examine live cows per rectum. An isolation station and scenarios enable students to consider biohazards and disease control measures.

Conclusions: An innovative yet pragmatic approach to developing models and associated supporting learning resources has allowed us to incorporate a 'vertical theme' of farm animal clinical skills throughout the new curriculum. The models are used in many taught classes and students are encouraged to return to the CSL for further self-directed learning as and when required, complementing clinical training while promoting and protecting animal welfare. The clinical skills initiative is the work of a dedicated team who have included academic and technical staff, recent graduates and students.

P01-001-006

Digital communication and knowledge transfer for veterinary practitioners and their client animal owners in Ireland

DJ Bosco Cowley^{1*}

¹MSD Animal Health, Dublin, Ireland

Objectives: Digital devices and channels are becoming more critical to effective knowledge transfer. To address a dearth of publications on the evolution and uptake of digital technologies, regarding Registered Veterinary Practitioners (RVPs) in Ireland and on their bovine client animal owners (CAOs), the aims of this research are to:

- Compare adoption of digital technology devices among RVPs and cattle owners to general population survey data
- Evaluate digital communication and education by the RVPs and their CAOs
- Determine relative importance of their information sources
- Evaluate patterns of their online behaviour regarding animal healthcare

Materials and Methods: A paper-based survey on uptake of digital devices, communication and online behaviour concerning sources of information and education was conducted by MSD Animal Health (MSD AH) Ireland, of RVPs, by convenience sampling at veterinary meetings in Ireland (≥ 2 per province) between November 2014 and March 2016. Cattle farmers were also targeted with a paper-based survey, comprising the same topics but tailored to farmers, at meetings conducted by MSD AH and other organisations (Teagasc), between July 2015 and March 2016. RVP uptake of websites and social media was evaluated. Digital adoption, communication and online behaviour data were gathered from the surveys of the target personas and the general population for comparison. Survey results were statistically analysed using a software package (STATA®) and tabulated.

Results: Website ownership or social media activity by RVPs varied between 50-80%, significantly associated with practice size. Facebook usage was correlated to presence of a website. Websites are used to market the practice through organic search, but also to educate their owners on animal care, more commonly for companion animals than ruminants. RVPs most commonly communicated information to clients via SMS text followed by hard copy and email. Only one third of vets communicated with their clients via social media. The majority of RVPs own a laptop, with approximately 2/3 owning a smartphone and only 1/5 owning a tablet device. Whilst almost 1/2 of vets use search engines weekly, colleagues, journals and conferences ranked in descending order as information sources.

The majority of cattle owners viewed the RVP as the most importance source of animal health (AH) information with the Irish Farmers Journal (IFJ) considered the next most important. The IFJ was the most frequently used website for seeking AH information after Google. Farmers significantly preferred email over text, phone or mail as the communication method from their vet for herd health information, though few read e-newsletters. Approximately 3/4 of farmers owned a smartphone, 1/2 a laptop and only 1/4 a tablet device. Smartphones were more or less equally used for email, telephony, text and internet surfing but less for social media. 1/3 of farmers read their emails every day and an additional 1/3 a few times per week. Social media usage by farmers was significantly lower than the general population.

Conclusions: The RVP has a significant role to play as a trusted educator on herd health. To capitalise on this position, they must consider the most appropriate means of dissemination of credible material across the preferred device and channel. Email may replace text as the preferred communication tool for farmers as the smartphone dominates. For successful information transfer, media must encourage a higher engagement rate with content than currently exists with e-newsletters.

Using a Massive Open Online Course (MOOC) to increase the reach of veterinary education

James Lowe¹ Brian Aldridge¹ Jason Mock² Colleen Cook² Katie Woodruff²

¹Veterinary Clinical Medicine, ²Center for Innovative Teaching and Learning, University of Illinois, Urbana, IL, United States

Objectives: Transferring new and existing knowledge and technological advances across the globe will be critical in feeding 9 billion people by 2050. The US has a long-established, highly successful model with the Agricultural Extension System to disseminate information to producers

and veterinarians. We explored how this model could be expanded to have a global reach by applying novel, online learning technologies, through Massive Open Online Courses (MOOC).

Materials and Methods: We developed a six module MOOC for the Coursera® platform entitled Sustainable Food Production Through Livestock Health Management that was delivered in the Spring of 2015. Each of the six modules explored a single aspect of how disease impacts the sustainability of food production. As part of each module, participants participated in discussion forums around their areas of interest and completed knowledge assessments. A capstone project was available for participants that wanted to deepen their learning. The course was provided at no cost to participants.

Results: A total of 8847 people joined with 5238 people completing at least part of the course. Participants were from 165 different countries with 35% from emerging economies. Between 379 and 1049 people completed the quiz each week with a reduction in number each week over time. The number and diversity of people reached by this program were much greater than though traditional educational platforms. Participation and completion rates are above the median for other courses at our institution.

The number and diversity of people reached by this program were much greater than though traditional educational platforms. Participation and completion rates are above the median for other courses at our institution. The data suggest that many people are interested in learning but choose to select the material that they want and may not be interested in traditional "course" based learning. This fits with a macro trend of a preference for competency development programs instead of credential granting training. The MOOC format while not perfected, creates an intriguing way to disseminate knowledge outside of traditional channels to increase the impact of institutions.

Conclusions: The data suggest that many people are interested in learning but choose to select the material that they want and may not be interested in traditional "course" based learning. This fits with a macro trend of a preference for competency development programs instead of credential granting training. The MOOC format while not perfected, creates an intriguing way to disseminate knowledge outside of traditional channels to increase the impact of institutions.

Utility of an online learning module for teaching disbudding in dairy calves, including cornual nerve block application.

Charlotte Winder¹ Stephen J. LeBlanc¹ Derek B. Haley¹ Kerry D. Lissimore¹ M. A. Godkin² Todd F. Duffield¹

¹Population Medicine, University of Guelph, ²Ontario Ministry of Agriculture, Food and Rural Affairs, Guelph, Canada

Objectives: The objective of this study was to determine if an online, interactive module could teach naïve participants appropriate disbudding technique, including application of a cornual nerve block, as compared to small group, hands-on learning.

Materials and Methods: Thirty-four student volunteer participants, with no prior experience with application of a cornual nerve block, were randomly assigned into two training categories; online, or hands-on. Volunteers were students enrolled in year 1 or 2 of the Doctor of Veterinary Medicine program (DVM) at the Ontario Veterinary College

(OVC), graduate students, or undergraduate students at the University of Guelph.

Hands-on learners were taught in groups of 2 to 4 by a registered veterinary technician (RVT), responsible for similar teaching in year 4 of the OVC DVM curriculum. An established protocol was followed, where students watched a demonstration disbudding of one calf, followed by the opportunity to practice on a single horn bud, with as much assistance as needed. Online learners were given access to an interactive training module that was developed based on the established hands-on protocol.

Evaluations were done in groups of 3 to 4 students, with at least 1 student from each treatment group. All evaluations were by a single, blinded, evaluator. Participants were scored on background knowledge by a written quiz, and scored on handling, block technique, and disbudding technique, by an established rubric. Time taken for each step of disbudding was measured, and participants were asked to rate their confidence on a score of 1 to 5 both before and after evaluation.

Calves were considered to be inadequately blocked if they performed any of seven established behaviors during the first five seconds of disbudding iron application, and a 'rescue' was performed by the RVT, who re-blocked the calf.

Results: Twenty-five percent of calves in the online group were considered inadequately blocked, and required a 'rescue'. No calves in the hands-on group were considered inadequately blocked. This result was not statistically significant (Fisher's Exact, $p=0.126$).

Online participants had significantly higher written test scores ($p=0.038$), but significantly lower handling scores ($p=0.023$) and disbudding scores (0.041). Technical scores for block application were not significantly different between groups.

Time taken was significantly longer in the online group; an additional 16.50 sec for blocking ($p=0.025$) and an additional 33.32 sec for disbudding ($p=0.010$).

Online participants were significantly less confident prior to evaluation (-0.70 , $p=0.001$), however, post-evaluation confidence scores were not different between groups. Online participants tended to have a greater change in score between pre- and post- evaluation ($+0.49$, $p=0.063$).

Conclusions: Online training was moderately effective at teaching naïve participants to successfully block and disbud a dairy calf. Although no statistical difference in block efficacy was seen, the numerical tendency for online learners to be less effective might approach significance if the trial involved more participants.

Online learners were less confident, had poorer handling skills, and took more time. After the evaluation, online learners' confidence score tended to increase compared to the hands-on group's, suggesting the importance of actual experience. Best practices for may involve a combination of both online and hands-on learning.

Outcomes from a training program to attract, upskill and retain veterinarians in the Australian dairy industry

Michael Pyman^{1,*}

¹Faculty of Veterinary and Agricultural Sciences, University of Melbourne, Melbourne, Australia

Objectives: Rural veterinary practices have found it difficult to attract and retain early to mid-career veterinarians risking a reduction in rural veterinary services, particularly in dairying areas where veterinary expertise is critical to farm productivity. The first two rotations of a three-year rural veterinary training program led by the University of Melbourne has provided the Australian dairy industry with a much needed boost in the availability of skilled dairy veterinarians who are now embarking on rewarding and productive career paths in the agricultural sector.

Materials and Methods: The training scheme sourced young veterinarians with an interest in dairy medicine and production to undertake post graduate training whilst embedded in one of six large, mixed veterinary practices located in the major dairying regions of Victoria and Tasmania. They were enrolled in a Master of Veterinary Studies (by course work) and a Master of Veterinary Science (by research) over three years. During that time they conducted farm-based research useful to the dairy industry; increased their capability to contribute to industry by skills acquisition through advanced clinical training; and acted as tutors, role models and mentors to veterinary students. The advanced training led to an understanding of the integration of farming systems within and beyond practice to enable them to develop expertise in whole-farm production programs such as fertility, herd health, mastitis & animal welfare. During training, the students were exposed to a wide selection of scientific and dairy industry experts, significantly broadening their industry knowledge and skills.

Furthermore, all participants were required to present their research results and other project findings in a variety of forums, including local and regional farmer meetings, the Australian agricultural media and various national and international scientific meetings and journals. This ensured the wide dissemination of practical outcomes from their farm-based research which in turn has encouraged students and veterinarians to consider career opportunities offered through the dairy industry in a variety of Australian regions.

Results: A major outcome of the program has been the number of important local animal health and production problems studied by the postgraduate students as part of their training. Research was conducted with full academic rigour and support and has led to economically viable solutions to many of the issues. The projects have included identifying management factors that could reduce prevalence of anoestrus in Victorian dairy herds; quantifying reasons for dairy herd bull infertility; identifying effective and practical colostrum management guidelines and factors affecting colostrum quality; confirming the presence of anthelmintic resistant parasites in Victorian dairy cattle; use of daily weight measurements as a predictive tool for reproductive performance; and the prevalence and associated risk factors of heifer mastitis in Victoria.

Each resident has published peer reviewed manuscripts, delivered extension activities and submitted reports detailing their activity over the three years. University of Melbourne veterinary students undertaking a compulsory two week dairy rotation in one of the six partner practices have recorded overwhelming approval for the scheme, highlighting the benefit of seeing dairy practice with enthusiastic and motivated young dairy veterinarians.

In practical terms the program has trained seven dairy residents with six awarded MVS/MVSc degrees and one converted to a PhD. Another graduate commenced a PhD at the completion of her Masters study and the remaining graduates have accepted consulting roles with dairy practices or the wider agricultural industry.

Conclusions: The program has provided a unique opportunity for professionals to develop skills and knowledge across the complete production chain from farm gate through the manufacturing process to the consumer, equipping them to make contributions to the industry, both in research and in knowledge transfer.

Most importantly it has allowed the major funding bodies to leverage their

investment for the benefit of the whole industry rather than a specific section or group.

Reverse engineering in animal science: visual perception of body condition score differences in three-dimensional models of cattle

Joao H. Viana¹ Eduardo K. Arashiro² Miller P. Palhao³ Carlos A. Fernandes³ Luiz G. Siqueira² Paulo J. Bartolo⁴

¹Animal reproduction, Embrapa, Brasilia, ²Animal reproduction, Embrapa, Juiz de Fora, ³Animal reproduction, University of Alfenas, Alfenas, Brazil, ⁴MACE, University of Manchester, Manchester, United Kingdom

Objectives: The evaluation of body condition score (BCS) is widely used in the management of cattle. Changes in BCS reflects mobilization of energy reserves, with direct consequences for production, reproduction, and animal welfare. The rapid generation of 3D models can be an important alternative to conventional strategies for the evaluation of BCS. However, in most cases, the obtained 3D models are not colored, which may condition users perceptions. The aim of this research study was to investigate the combined used of scanning technologies and 3D modeling to access its effects on the visual perception of BCS.

Materials and Methods: Conventional photographs and 3D data of the lumbar, pelvic, and tail head regions were obtained from Holstein-Gir crossbred dairy cows (n=67). Digital color photos were taken from the upper-rear view of each cow, while 3D data were recovered by structured infrared light scanning of the same area, using a sensor equipped with built-in infrared projector and infrared and RGB video cameras. A 3D model of each cow was created using a real-time 3D scanning software (ReconstructMe 2.0), and edited using an open-source software for processing 3D triangular meshes (MeshLab). The 3D models were then rotated in the X-Y-Z axes to provide a view of each cow equivalent to that used to take the photo, and snapshots were made and stored as TIFF files. Three experienced evaluators (E1, E2, and E3) independently assigned BCS to the cows using the photos and the snapshots of the 3D models, with the same reference procedure and scale (1 to 5), without knowing the identification of the cows nor the relationship between pictures (blind evaluation). The main effect of the image type (photo or snapshot) and the effects of cow, evaluator, and their interactions, were included in the statistic model, and analyzed with the GLM procedure of the SAS software. The association between BCS outcomes was calculated using the Pearson's correlation method. The correlations were compared using a package for R programming language (comparingcorrelations.org). Data are described as mean \pm SEM. A p-value of 0.05 indicated statistical significance.

Results: There was no difference in average BCS determined using the 3D model snapshots or the conventional color photos (2.85 \pm 0.21 vs 3.03 \pm 0.22, respectively; P = 0.79). The BCS were affected by cow (P = 0.04) and evaluator (P = 0.04), but there was no interaction of image type and cow (P = 0.46) or evaluator (P = 0.07). The correlations between BCS values for the evaluators were not affected by image type (R = 0.79 vs R = 0.84 for E1 x E2, P = 0.41; R = 0.85 vs R = 0.91 for E1 x E3, P = 0.13; and R = 0.79 vs R = 0.81 for E2 x E3, P = 0.76; for photos or snapshots, respectively).

Conclusions: The use of virtual models constructed by 3D data acquisition and 3D modeling, despite lack color information, does not

interfere in the perception of BCS, and thus can be used for educational/training purposes. These models have many potential advantages, including preserving the correct proportions of the original models, and the possibility of being rotated in the virtual space and explored in different angles. Moreover, they can be used in enhanced reality, or 3D printed to provide tactile experience, e.g., to mimic the BCS evaluation techniques that associate visual and tactile information.

The Group of Study, Research and Extension in Goats and Sheep (GEPECO) of the Universidade Federal Fluminense, Brazil

Mario Balara¹ Ana Clara S. Ribeiro¹ Karina F. Delgado¹ Alex S. Santos¹ Luiza M. Cavalcanti¹ Loara Helena S. Gonçalves¹ Juliana Brito¹ Sarah C. Schramm¹ Luiz Fernando G. M. Moura¹ Felipe Z. Brandão¹

¹Clinical and Animal Pathology, Universidade Federal Fluminense, Niteroi, Brazil

Objectives: The group aims to support the consolidation and profitability of the sheep and goat production at Rio de Janeiro State. To achieve this goal, we have been working with the development of special skills in students of veterinary medicine with the association of research and extension activities in the segment.

Materials and Methods: The Group of Study, Research and Extension in Goats and Sheep (GEPECO) is formed by undergraduate and postgraduate vet students, coordinated by associate professors of the Veterinary Faculty. The students develop skills in the sheep and goat unit of the Farm School and later they exercise along the extension actions in farms assisted by the group. At each meeting, a new practice theme is presented to students. The main themes are: (1) facilities, ambience and Animal Welfare; (2) Strategic Parasite Control and vaccination protocols; (3) Nutrition and pasture management; (4) Reproductive management; (5) Medical Clinic and routine surgical procedures; (6) Breeding and profitability of the activity; (7) Industrial processing of meat and milk - visits to slaughterhouses and dairy factories. Prior to visiting the property, the group discusses about the procedures to be performed. All visits are guided by a postgraduate vet student or professor who deals with the farmer and performs the activities with the help of the students involved. Furthermore, the students also learn the language used with it and the different measures may be adopted in accordance with the socio-economic realities encountered. Thus, the extension actions encourage the adaptability of the students, future professionals, teaching him how to act in front of different circumstances, stimulating creativity and confidence of them. It also has been done applied research, conducted by postgraduate students, with farm partners aiming to solve issues reported previously by them and minimizing production costs.

Results: The GEPECO has trained 43 vet students since 2008. It has also participated and has exhibited scientific findings on conferences. Moreover, it has helped to make up for the lack of existing technology in the sheep and goat production through of the extension actions. Nowadays, the group assists eight farms, from larger commercial to familiar production systems with important social role. Most of them are located on the outskirts of the Farm School. The most challenges for farmers are related to labor hand on the property and nutrition issues. Among the activities developed by the group in these farms, the examination of eggs per gram of feces in association with Famacha[®] technique for

the deworming control strategy have been done. Vaccination procedures and changes in some management were also successful to control outbreaks of infectious diseases. The use of hormonal protocols in the breeding and out-breeding season in association with the ultrasound diagnosis of early pregnancy has helped to optimize the reproductive gains. Furthermore, monitoring of the animal production and culling procedures have also been contributed to improve genetic gains in each farm. At long last, students will incorporate these techniques to use in their professional life, as well as the farmers are benefited by optimizing the production system.

Conclusions: The GEPECO collaborates in the development of skills and professional insertion of students of veterinary medicine, in food production, in the rural revenue of sheep and goat farming and keeping people in the countryside.

Comments: The authors believe that the inclusion of this abstract about the GEPECO, in the education topic, will be important to generate discussion and take criticism and suggestions on the same.

Teaching on farm biosecurity and welfare to future veterinarians, a professional practical training at UNIBO

Alessandra Scagliarini^{1,7} Angelo Peli² Giovanni Casà² Santino Prosperi² Gianluca Pignoni³ Olivia Melloni³ Lorenzo Scagliarini³ Francesca Matteucci³ Silvano Natalini³

¹Alma Mater Studiorum Università di Bologna, Ozzano Emilia (Bologna), Italy, ²Dipartimento di Scienze Mediche Veterinarie, Alma Mater Studiorum Università di Bologna, Ozzano Emilia (Bologna), ³Area Sanità Pubblica Veterinaria, AUSL Bologna, Bologna, Italy

Objectives: In an effort to prepare the next generation of veterinarians with the wealth of knowledge they need, the Department of Veterinary Medical Sciences (University of Bologna), in collaboration with the AUSL Public Health Area, included on-farm biosecurity training in the fifth year of the veterinary curriculum to prepare the students to think holistically about different livestock

Materials and Methods: During the activity, each student visit two properties: one small ruminant and one cattle farm and use the biosecurity and welfare checklists that are commonly employed during farm's official controls. Students are encouraged to ask questions to the owner and/or to the manager and collect samples for laboratory analyses which are subsequently analysed during laboratory activities. At the end of the activity, they turn into a communications exercise preparing and presenting a biosecurity plan that is given to the farmer.

Results: Sixty one farms been visited in 2014-2015 mainly in Emilia Romagna region. Small ruminant properties were mostly small sized dairy farms within 25 to 50 animals, but hobby and beef farms were also included. Cattle properties were mainly single or multi sides dairy farms with 200 to 1000 animals. Different issues related to livestock movements, management of equipment, waste, feral animals and pest and feed and water have been identified for each visited property. One of the main issues related to small ruminants was that 60% of the farms can not count on specialised veterinary assistance due to a lack of professionals working on this field in Emilia Romagna region. Environmental factors such as NH3 concentration is not perceived as a risk factor for respiratory diseases leading to a wide use of vaccines and

antibiotics to prevent and treat such disorders. Farmers are frequently not aware about SRLV contribute to new born mortality, mastitis, respiratory and CNS disorders even if more than 60% of small ruminant properties resulted infected.

Conclusions: The UNIBO practical training on biosecurity and welfare resulted in an increased awareness of last year students on the management measures that can be put in place to reduce the use of therapeutics and vaccines with positive impacts on farm economy and food safety. At the same time it consolidated the collaborations of the Academia with veterinary practitioners, farmers and veterinary officials in defining educational priorities for future veterinarians.

P01-001-013

Virtual visits to production units and real time information systems as a Zootechnics learning tool in the undergraduate studies of the FMVZ

Israel Daniel Ricardo¹ Leticia Blanco¹ Miguel Angel Blanco^{1*}

¹SEMZE, FACULTAD DE MEDICINA VETERINARIA Y ZOOTECNIA. UNAM., MEXICO.D.F., Mexico

Objectives: The aim of this project is to promote, increase and generalize the quality of teaching and learning of the future professionals of Veterinary Medicine and Zootechnics, through new approaches, logics and technologic and computer resources that will not only increase the responsibility of students in their learning process, but also contribute to a shared commitment between academics and students.

Materials and Methods: IP cameras in the area of the milking parlours for cows and goats at the CEIEPAA of the FMVZ-UNAM were installed during the development of the project. The cameras were interconnected with a real time transmission system, which in turn is available in the website of the Medicine, Zootechnics and Academic Extension Secretariat, as well as with a video archive system, which can be consulted in the same website. With a previous registration at the internet page, both the student and the professor can look at the real time transmission of the captured procedures. On the other hand, short-clips edited videos are also shown

Results: The results are in the internet page at the servers of the FMVZ-UNAM, following the link to "Departamento de Zootecnia", with the following website: <http://www.fmvz.unam.mx/zootecnia/>

In this internet page, one should follow the instructions depending on the computer's operating system:

When the complement is installed, the following screen will show, asking for:

Username ("Nombre de usuario"): basico (lower case, no accents)

Password ("Contraseña"): zootecnia (lower case)

Then, click the "LOGIN" button.

The user's interface is the following:

By default, only one camera is selected (as shown in A figure). The visualization menu is shown at the bottom part, allowing 4, 5 or more cameras to be selected at the same time (as shown in B figure).

Cameras 1, 2, 3, 4 and 9 are located in the milking parlours of cows, whereas cameras 5, 6, 7, 8 and 10 are in the milking parlours of goats.

The schedule for milking at the CEIEPAA is the following:

Cows: 8:00 am and 4:00 pm

Goats: 8:00 am

From the same website, there is an automatic access to the websites of FMVZ, the Medicine, Zootechnics and Academic Extension Secretariat and to the webpage of each of the seven Learning, Research and Extension Centre of the University.

Conclusions: The teaching of Veterinary Medicine and Zootechnics could be improved using information technologies and having access to these type of computer tools. Thereby, the students with the supervision of professors can reach to certain conclusions which are based in real systems of production, enabling them to develop a critical and analytical sense to make recommendations and increase the productivity in their future field of work. 1, 2 y 4

Comments: This work is part of the PAPIME PE201513. UNAM. Project "Virtual visits to the production units and real time information systems, as a Zootechnics learning tool in the undergraduate studies of the FMVZ"

The gamification of the classroom, or how to learn dairy management through playing

Sergio Calsamiglia ^{1*} Alfred Ferret ¹ Lorena Castillejos ¹ Gonzalo Vera ¹ Guillem Espinosa ¹

¹Servei de Nutricio i Benestar Animal, Univeritat Autònoma de Barcelona, Bellaterra-08193, Spain

Objectives: In the Bologna educational systems the student is in the center of the learning process, he has to work more independently, and an experienced-base environment is highly recommended. Case studies are excellent to develop thinking abilities and integrate concepts, but it imposes a burden on the instructor to generate a large number of cases and to grade them. The objective of this paper is to present a web-based dairy farm simulation model designed to be used in introductory courses of Dairy Herd Management in Veterinary and Animal Science studies.

Materials and Methods: The model is programmed in Java and is accessible by internet. Modeled events are based on physiological functions of cows and work at random around predefined averages and ranges. The program has three levels of interaction: the administrator that coordinates the system; the instructor that controls all conditions within his class and can visualize each individual student activity; and the student that controls all actions in his farms. At the beginning of the course, the instructor defines all parameters of the farms that will be assigned to students (farm size, production level, dietary ingredients available, fertility, detection rate, incidence of diseases,...) and the program generates a unique farm for each student within these limits. Actions taken by students include: heat detection, insemination, dry off, diet specifications, formation of groups and transfer of animals between groups, colostrums and milk feeding, weaning, treatment of diseases, milk withdrawal if antibiotics are used, buying and culling of cows or heifers, among others. The daily output provides information on milk production, economic performance and counters of errors incurred as feedback for students. The final grade is calculated automatically. Additional exercises based on their own farm (i.e., calculate required space for cows, land for forages production or manure spreading,...) can also be implemented.

Results: The web-based computer simulation model is an excellent strategy to generate an unlimited number of farms to allow students to take decisions individually and assume their consequences. The program can be used by the instructor as it is in introductory classes, but it may also be used in parallel to formal classes to illustrate specific concepts (i.e., the instructor can cause a change in forage quality or modify fertility and make students identify the problem and discuss the consequences at the dairy farm level). The program has been used for the last 5 years by undergraduate and Veterinary School students in different universities with excellent evaluations of the learning process from student surveys. In a non-planned exam conducted 2 weeks prior to the final exam, students were 5 times more likely to respond correctly to the same type of questions about dairy cows than other species taught in the same semester. The program is written in Catalan, Spanish and English. For information, connect to www.dairyfarm.es. Information provided includes a Manual for Instructors, a Manual for Students, a Quick-start guide, and two 12-minute videos with instructions for student and one 10-minute video with instructions for the instructor on how to use the program. The program is free of charge. To activate an account as instructor, send a request to sergio.calsamiglia@uab.es. The estimated amount of work for an introductory class is two-hour lecture and about 6 to 8 h of individual work per student.

Conclusions: The web-page dairy farm simulation program is an excellent tool for teaching introductory courses in Dairy Herd Management where students become in the center of the learning process by being responsible for all activities that take place in a dairy farm. It allows instructors to generate as many farms as students, and the grading is automatic.

Homepage about the fertility of the healthy cow with two animations: the cycle of the cows heat and the development of the gestation

Leonie Von Tavel ^{1*}

¹Reproduction, SWISSGENETICS, Zollikofen, Switzerland

Objectives: In 2010, the Swissgenetics company developed the idea to provide a homepage about the fertility of the healthy cow for their customers – the farmers and also for students of the veterinary medicine. This as a possibility to increase the customer loyalty. The homepage had to be presented in German and French, later maybe in English, too. The number of visitors should reach at least 5% of the total number of accesses on www.swissgenetics.ch

Materials and Methods: A mind map was generated for each chapter after discussion with veterinarians and agronomists. With aid of the common literature, the themes were deepened. All texts were written by a veterinarian specialised for cows. For each theme, pictures, films, interviews or animations (the cycle of the cows heat and the development of the gestation) were generated or added. The program used for the construction of the website was TYPO3.

The website has been promoted in lessons at agricultural schools, newspaper advertisement and newsletters.

Results: www.die-fruchtbare-kuh.ch (in German) and www.la-vache-fertile.ch (in French)

The cycle of the cows heat and the development of the gestation are shown in two extraordinary animations. Seven chapters were elaborated: the fertile cow, the cow with disturbances of fertility, heat detection, insemination, birth and breeding, herd management and signals of cows. On the front page, there are rotating themes of articles, signals of cows, news and the two animations.

With a photograph contest about signals of cows in January-March 2015, the number of visitors increased intensely. Since then, twice per month, a signal of cows is analysed in the newsletters of Swissgenetics and of the homepage. A professional film about the birth of the calf brought more than 300'000 visitors (channel of youtube).

Conclusions: To establish such a homepage, several years are needed. With special designs like the cycle of the cows heat and the development of the gestation, the homepage becomes inimitable. Regular promotion is necessary. With the contest for the customers on a popular subject, the number of visitors increased rapidly. It stays at the aimed level thanks to the rotating information on the front page and its professionalism.

Cattle diseases: physical sign profile similarities using sign frequency pattern recognition

Peter Cockcroft^{1*}

¹School of Animal and Veterinary Sciences, University of Adelaide, Adelaide, Australia

Objectives: An important step in the formation of a list of differential diagnosis in clinical practice is the identification of diseases that are similar in clinical profile to the leading hypothesis. The objective of this study was to generate a similarity chart and an ordered list based upon sign profiles and frequencies within cattle diseases.

Materials and Methods: The data contained within the diagnostic expert system Bovid 3 was used as the source data. This data was derived from expert opinion and contained the sign frequencies for over 1100 cattle diseases across a comprehensive range of clinical signs. Only physical signs were used in the analysis. The data was entered into a software program which used a simple linear nearest neighbour comparison based upon the differences between the disease sign frequencies to compute the similarities. The outcome is presented in a dendrogram format and a list.

Results: The output was a chart indicating the similarity of the diseases in a hierarchy and an ordered list with adjacent diseases being the most similar to each other. Each disease is placed next to the disease with the greatest similarity according to the array of sign frequencies within the disease profile. The order of the diseases indicates the relative profile differences between the diseases. The relative prevalences can be represent either numerically or by colour coding. Alternatively the database of diseases can be limited to common diseases only.

Conclusions: This study has provided a resource for differential diagnosis in clinical practice and a classification of diseases which could be used in problem based learning. The dendrogram represent a taxonomy of cattle diseases according to the array of physical sign frequencies within the disease profile.

Dynamics of Anti-Schmallenberg Virus Antibodies in a Naturally Infected Dairy Cattle Herd

Mark Holsteg¹, Kerstin Wernike², Michael Sasserath³, Martin Beer²

¹Bovine Health Service, Chamber of Agriculture for North Rhine-Westphalia, 53229 Bonn, ²Institute of Diagnostic Virology, Friedrich-Loeffler-Institut, 17493 Greifswald, ³Institute of Diagnostic Virology, State Veterinary Institute Krefeld, 47798 Krefeld, Germany

Objectives: In late 2011, the novel insect-transmitted orthobunyavirus Schmallenberg virus (SBV) emerged in Central Europe. Aim of this study was to investigate the development of SBV seroprevalence and duration of immunity in naturally infected animals in one Herd in the years 2011 - 2014.

Materials and Methods: All cows older than 24 month were blood-sampled in December 2011 or January 2012 (total of 311 animals), again in January 2013 (331 animals), in December 2013 (324 animals), and in December 2014 (330 animals). From 122 cattle blood samples were available from all four sampling dates. The cows included in the study were kept indoors year-round, but all animals younger than 24 month are kept outside. All samples were taken by jugular venipuncture by the responsible farm veterinarian in the context of the health monitoring program of the farm under the control of the Bovine Health Service (Chamber of Agriculture for North Rhine-Westphalia) and analyzed by a commercially available SBV antibody ELISA (ID Screen® Schmallenberg virus Competition, ID vet, France), using the recommended cut-off of 40% relative optical density compared to the negative control (S/N, %). All samples taken from an animal were tested on the identical ELISA plate.

Results: In December 2011, in 74% of the tested animals SBV-specific antibodies were detectable. Additional scattered seroconversions were observed between the 2011 and 2012 vector seasons, thereafter all seronegative animals remained negative. Until December 2014, the intra-herd seroprevalence decreased to 58%. This lower number of animals with measurable anti-SBV antibodies is most likely caused by the missing infection of the young stock, especially as the year with the highest virus circulation was 2011 and the proportion of animals born after 2011 among the blood-sampled increased from 2013 to 2014 since older animals are gradually replaced by the offspring. A total of 122 cows infected presumable in autumn 2011 were sampled every year, 9 of them became seronegative until December 2014.

Conclusions: Consequently, though SBV-specific antibodies were detected in about 90% of the monitored animals for more than three years, a lifelong antibody-based immunity is not expected in every animal. The loss of anti-SBV antibodies in individual animals combined with the missing infection of young stock results in a declining herd seroprevalence and increases the risk of a renewed virus circulation to a greater extent within the next years.

Schmallenberg virus detection the bull semen in Poland

Julia Kęsik-Maliszewska¹, Magdalena Larska¹

¹Department of Virology, National Veterinary Research Institute, Puławy, Poland

Objectives: Detection of Schmallenberg virus (SBV) in bull semen raised a concern in genital transmission to susceptible germplasm recipients. SBV RNA was detected yet only in bovine semen, limited studies in experimentally infected ram and buck failed to detect the virus. Recent study showed infection of transgenic mice and cattle after subcutaneous injection with SBV positive semen. Viral RNA has been detected in the bull semen with variable dynamics even after three months from seroconversion. The objective of the study was to evaluate SBV presence genetic material in bull semen in Poland.

Materials and Methods: Semen samples from 131 bulls collected between 2013 and 2015 from four herds spread across the country. The serological status of individual animals was unknown. SBV DNA standard (a product of rt-RT-PCR- DNA strand, complementary to the RNA segment of SBV-S template) was prepared in order to optimize the protocol and evaluate the efficiency and sensitivity of different RNA extraction methods. Four extraction methods (3 commercial silica membrane-based methods and Chomczynski based method of TRI extraction) were assessed for level of β -actin (internal control of amplification) and recovery rate of prepared DNA standard detected in rt-RT-PCR in semen. Tenfold dilutions of DNA standard in TE buffer and SBV DNA-spiked semen were prepared and after extraction (each method) RT-PCR was performed. Two pairs of primers designed to detect SBV-S segment and β -actin gene as internal control were used in the standard real-time RT-PCR developed at FLI (Riems, Germany) using AgPath-ID One-Step RT-PCR Reagents (Ambion, Applied Biosystem) kit in StepOne Real-Time PCR system (Life Technologies). The reaction was considered positive when a Ct value < 40 was obtained both for SBV-S and β -actin.

Results: Seven semen samples out of 131 (5,3%) tested were positive for the presence of SBV RNA with Ct values between 34.5 and 37.2. Positive samples originated from two out of four herds and accounted for 4.8% (3 out of 63 bulls) and 13.3% (4 out of 30 bulls) of the samples tested from those two locations. SBV genetic material was detected in semen collected in 2014 except one from end of 2013.

From the four tested extraction methods, Viral RNA Mini Kit (Qiagen) was selected as the most sensitive method allowing detection of 10 copies of viral DNA per reaction and PCR efficiency of 104% in standard DNA-spiked semen. The extraction method resulted in the lowest levels of Ct values for β -actin in the commercially diluted semen sample which probably due to some inhibitors which affected negatively other extraction methods tested. And finally, Viral RNA Mini Kit needed only 140 μ l of semen what is also significant when testing semen samples frozen in straws. The detection limit of 1 copy per reaction and efficiency 93.1% was established for the DNA standard diluted in TE buffer. This demonstrates that semen extraction method which was chosen and semen as a potentially inhibiting medium did not decrease substantially the detectability of SBV.

Conclusions: The presence of viral RNA in the semen suggests quite recent SBV outbreaks in the two bull herds, however the source has not been identified. This discovery confirms that even in low virus circulation in vector and high seroprevalence new infections occur. The presence of virus genetic material in the tested semen does not implicate directly its infectivity. However, the risk of SBV transmission through artificial insemination or mating should not be ignored and the emergence of new outbreaks in naïve herds should be considered. Since SBV was detected in gonadal tissues virus infection in aspect of germplasm quality should be considered.

Zulvac® SBV, a vaccine against Schmallenberg virus in breeding sheep that reduces viremia and transplacental infection

Berta Alberca¹, Mercedes Mouriño¹, Mònica Balasch¹, Frédéric Descamps², Lúdia Garcia¹, Helena Paradell¹, Elisenda Viaplana¹, Anna Vila¹, Alicia Urniza³ and VMRD Department Zoetis Olot

¹VMRD, Zoetis, La Vall de Bianya (Girona), Spain, ²VMRD VMRA, ³VMRD, Zoetis, Zaventem, Belgium

Objectives: The Schmallenberg virus (SBV) was first identified in Germany (2011). SBV is transmitted mainly by biting midges (*Culicoides* genus) and can infect cattle, sheep and goats. SBV rapidly spread in Europe causing mild transient disease in adults (i.e. drop in milk production, fever, diarrhea) but main losses are associated with the infection during pregnancy due to SBV ability to cross placental barrier causing congenital infection.

The aim of this study is to evaluate the efficacy of Zulvac® SBV in breeding sheep by evaluating the reduction of viremia and transplacental infection associated with SBV infection during the first half of pregnancy.

Materials and Methods: The Zulvac® SBV vaccine is a suspension for injection intended for active immunization of cattle and sheep against SBV. The active substance is the inactivated SBV strain BH80/11-4 adjuvanted with aluminium hydroxide and saponin.

Thirteen (13) ewes at breeding age were vaccinated according to the vaccination schedule: two doses of 1 mL three weeks apart by subcutaneous route in the axillar region. Fifteen (15) ewes were left unvaccinated as controls.

Fourteen days after the second dose, animals were naturally mated and approximately at 50 days of gestation the animals were challenged with SBV inoculum. After the experimental infection, blood samples were collected to evaluate the presence of genome in the ewes' blood and amniotic fluid samples were collected to detect the presence of virus genome. Ewes were also monitored for the appearance of clinical signs and hyperthermia.

Twenty-five days after challenge (approximately 75 days of pregnancy) ewes were euthanized and samples were taken from ewes and fetuses to assess the absence of viremia and prevention of transplacental infection.

Results: Before challenge, animals vaccinated with Zulvac® SBV vaccine presented neutralizing antibodies against SBV whereas the unvaccinated remained negative.

After challenge, neither the vaccinated nor the control ewes demonstrated any clinical signs associated with SBV infection, with the exception that control ewes presented a higher rectal temperature 4 and 5 days post-infection compared to the vaccinated animals.

There was a prevention of viremia in 92% of the vaccinated ewes (SBV genome was only detected in 1 vaccinated animal for 1 day), whereas 93% of the unvaccinated ewes developed viremia.

SBV genome was not detected neither in the amniotic fluid nor in any of the fetuses' samples from vaccinated ewes, while SBV genome was detected in the amniotic fluid and/or fetuses' samples of 45% of the unvaccinated ewes.

Conclusions: Zulvac® SBV administered in sheep at breeding age has been shown to prevent viraemia associated with SBV infection in 92% of

the vaccinated animals and prevent transplacental infection in 100% of the vaccinated and infected ewes.

It can be concluded that Zulvac® SBV vaccine provides a prevention strategy against SBV as this is the first vaccine against SBV in cattle and sheep centrally authorized in the EU.

Genotyping of Leptospira Strains Isolated from Cattle in Argentina

Luis Samartino^{1,2}, Bibiana F. Brihuega^{1,3}, Silvia Grune¹, Carmelo T. Auteri¹, Graciela Romero¹

¹Pathobiology, National Institute of Agriculture Technology (Veterinary Research Center), ²Veterinary, University of Salvador, Hurlingham Buenos Aires, ³Veterinary, University of Salvador, Pilar, Buenos Aires, Argentina

Objectives: Leptospirosis is a worldwide zoonotic infectious disease which induces abortions, stillborns and weak offspring in cattle. Bovine leptospirosis is frequently diagnosed in our laboratory by serology, bacteriology and molecular methods. Because of the high genetic variation present in this spirochete, the molecular typing of the prevalent pathogenic strains is important for the determination of surveillance, prevention and control strategies according to the actual epidemiological scenario. The purpose of this study was to molecularly genotype the pathogenic *Leptospira* strains isolated from clinical cases of cattle in Argentina.

Materials and Methods: *Leptospira* was isolated from abortions produced in dairy farms in Buenos Aires Province. Fetus was collected and processed within 24 hours in the laboratory. In other case, kidney was collected from slaughterhouses. Immunofluorescence was done and was positive in all cases. Genotyping was performed using the Multiple-Locus Variable-number tandem repeats Analysis (MLVA). This technique was used with one set of oligonucleotides specific for the pathogenic strain *Leptospira interrogans sensu stricto*. The following loci were used to discriminate the strains, VNTRS: 4, 7, 9, 10, 19, 23 and 31. Fifteen bovine-isolated strains were genotyped by MLVA.

Results: The strains were genotyped by MLVA obtaining the following:

- 1- Two genotypes of *Canicola Portlandvere* and eight genotypes of *Pomona Pomona* isolated from bovine abortions;
- 2- One genotype of *Hardjo Hardjoprajitno* and two genotypes of *Canicola Hond Utrecht IV*, from bovine kidneys from slaughterhouses;
- 3. Two genotypes of *Icterohaemorrhagiae RGA* isolated from kidneys of calves.

The results of this experiment show the wide range of genotypes present in the isolated *Leptospira* strains of in Argentinean cattle.

Conclusions: In conclusion, it is recommended to use detailed surveys in all endemic regions in order to detect new genotypes and to analyze if new genotypes should be included in the current vaccines to prevent bovine leptospirosis according to the country or region.

The dynamics of Schmallenberg virus circulation in *Culicoides* spp. midges after the transmission of virus to Poland in 2012.

Magdalena Larska¹ Julia Kęsik-Maliszewska^{1*}¹Department of Virology, National Veterinary Research Institute, Puławy, Poland

Objectives: The Schmallenberg virus (SBV) is a novel arthropod-borne pathogen transmitted by blood sucking female midges of *Culicoides* genus which has emerged in Europe in 2011. In August 2012, SBV was first detected in cattle and *Culicoides* spp. midges in Poland. Subsequently, the circulation of SBV was detected in over 10% midge pools collected during the 2012 activity season. The virus has been recovered also from the nulliparous females which may suggest transovarial transmission. The further studies were performed in order to determine the prevalence of SBV in subsequent years and the possibility of SBV overwintering in the *Culicoides* vector.

Materials and Methods: *Culicoides* spp. midges were collected using Onderstepoort and Model CDC 1212 John W. Hock Company UV light traps set in 23-26 evenly distributed locations in the country between 2013 and 2015. Most traps were located in a proximity of domestic ruminant farms, while two traps were placed near the rest places of European bison (*Bison bonasus*) at the breeding reserves of Białowieża National Park (BNP) at Białowieża Primeval Forest. The midges were separated and pooled (mean 24 individuals) according to species, parity status, location and date of collection. Over 3000 pools were tested. The insects were homogenized in RLT Buffer using Lysing Matrix D Tubes with ceramic beads in Ryzolizer. Total RNA was extracted using RNeasy Mini Kit (Qiagen) in the automatic station Qiacube (Qiagen). Two pairs of primers designed to detect SBV S segment and a fragment of 18S midge gene as internal control were used in the in-house optimized real-time RT-PCR using AgPath-ID One-Step RT-PCR Reagents (Ambion, Applied Biosystem) kit in StepOne Real-Time PCR system (Life Technologies). The SBV positive midge pools were retested in order to verify the result.

Results: The percentages of SBV positive *Culicoides* pools were 0.9% (13/1401) and 1.1% (18/1569) in 2013 and 2014, respectively. The mean Ct values high and reached 39.4 and 34.7 in those two years. SBV was detected in 2.8% (8/283) midge pools collected in 2015 with the mean Ct value of 38.6, however the testing has not been finished by the time the abstract was prepared. SBV RNA has not been detected in any of the midges from BNP in 2014 and 2015.

Similarly to 2012, midges belonging to *Culicoides* *obsoletus*/*scoticus* complex species were the most predominant vector of SBV in Poland. The second important vector species was *C. punctatus*. One positive *C. chiopterus* pool was detected in 2013. Positive nulliparous pools (young females which have not taken any blood meal yet) were detected in each year tested what may suggest independent from ruminant virus circulation in the midge population.

SBV positive pools were detected at the same locations in the consecutive years which shows continuous circulation of the virus despite the intra-seasonal lack of insect activity (possible 'overwintering').

Conclusions: Decline in the percentage of positive pools as well as in the mean load of SBV RNA in 2013-2015 in respect to 2012 suggests low SBV infection rate and possible virus clearance in Poland. This corresponds to the slow increase of seroprevalence observed in farm animals between 2013 and 2014. Therefore, vector SBV monitoring seems useful in order to study the dynamics of the virus spread in the country. SBV overwintering may be connected to the continuous circulation also due to transovarial transmission in the midges.

Emerging Diseases

P02-002-075

Species composition, abundance and new geographical species identification of *Culicoides* biting midges on dairy farms

Aine B. Collins^{1,2*} John F. Mee¹ Michael Doherty² Damien Barrett³ Marion England⁴¹Animal and Bioscience Research, Teagasc, Fermoy, ²School of Veterinary Medicine, UCD, Dublin, ³Sligo Regional Vet Lab, DAFM, Sligo, Ireland, ⁴The Pirbright Institute, Woking, United Kingdom

Objectives: *Culicoides* biting midges can transmit over 50 arboviruses worldwide including bluetongue virus (BTV) and Schmallenberg virus (SBV). In northern Europe, six species (*C. obsoletus*, *C. scoticus*, *C. dewulfi*, *C. chiopterus*, *C. pulicaris* and *C. punctatus*) are considered to be vectors of veterinary concern. The emergence of BTV and SBV in northern Europe has highlighted the susceptibility of domestic livestock to vector-borne diseases. To date there have been no published studies on these vectors on Irish dairy farms. Hence, the objective of this study was to investigate the species composition and abundance of *Culicoides* on dairy farms in Ireland.

Materials and Methods: Ultraviolet light trapping for *Culicoides* was conducted on 10 dairy farms located in the south of the Republic of Ireland. Each site was sampled fortnightly over 16 weeks (21st July – 5th November 2014). One Onderstepoort Veterinary Institute UV light trap was run overnight (dusk to dawn) in the vicinity of livestock on each farm. Catches were transferred immediately into 80% ethanol for storage. Subsequently, *Culicoides* were morphologically identified to species level. Collection site habitats were characterised using Phase 1 habitat survey technique (Joint Nature Conservation Committee).

Results: A total of 24,190 *Culicoides* (82% female) were collected from 10 farms in 68 successful trap collections. *Culicoides* were found ubiquitously across all sites; however, a large variation in *Culicoides* abundance between sites was observed (range 261-4,641 total *Culicoides*/farm). This may be due to between-farm differences in environmental factors, meteorological conditions or host availability. Collection site habitats were predominately improved grassland which included a mix of semi-natural woodland and hedges. A total of twenty-two different species of *Culicoides* were identified from trap catches. The most abundant species identified were the putative vectors of BTV and SBV (constituting 92.5% of *Culicoides* caught; *C. obsoletus*/*C. scoticus* [37%], *C. dewulfi* [36%], *C. chiopterus* [4.48%], *C. pulicaris* [9%] and *C. punctatus* [6%]) and these were found to be present on all farms. The remaining *Culicoides* species identified (7.5%) were principally the non-vector species *C. achrayi* and *C. festivipennis*. Additionally, within this percentile three non-vector species of *Culicoides* were identified for the first time in Ireland, constituting new records; *C. cameroni*, *C. clastrieri* and *C. manchuriensis*.

Conclusions: The most abundant species identified in this study were the putative vectors of BTV and SBV in northern Europe. These findings are consistent with previous studies carried out on dairy farms in parts of England. The presence and abundance of these *Culicoides* vector species amongst cattle on dairy farms in Ireland and the UK show that disease transmission could re-occur following a new incursion of BTV or SBV into these areas.

Emerging Diseases

P02-002-076

Pronghorn virus, genomic and antigenic characterization and detection in free ranging ungulates in the US.

Julia F. Ridpath^{1,2}, John D. Neill¹, Fernando V. Bauermann¹, Shollie M. Falkenberg², Peregrine L. Wolff³

¹Ruminant Diseases and Immunology, National Animal Disease Center/ ARS/USDA, Ames, IA, ²Cattle Vaccine R&D, Elanco, Indianapolis, Indiana, ³Nevada Department of Wildlife, State of Nevada, Reno, Nevada, United States

Objectives: In addition to the recognized/classic species within the pestivirus genus there are putative species. One of these is pronghorn virus (PHV). PHV was first isolated from an immature, blind pronghorn antelope in the state of Wyoming. The objectives of these studies were to determine level of genetic and antigenic cross reactivity between PHV and other pestivirus species, examine the incidence of exposure to the emerging pestivirus, pronghorn virus (PHV), in wild ungulate populations, and observe clinical presentation in domestic goats and white tail deer following exposure to PHV.

Materials and Methods: Sequencing of the genomic RNA of pronghorn virus from the cell culture supernatant was done using the Ion Torrent and Illumina MiSeq sequencing protocols, as previously described. The 3' end of the genomic RNA was confirmed by 3' RACE using a primer set designed to amplify the 3' terminal 600 bases. Hyperimmune sera against bovine viral diarrhoea virus 1 (BVDV1), BVDV2, border disease virus (BDV) or PHV were produced in goats and cross neutralization studies performed. Serum and whole blood was collected from mule deer, big horn sheep, mountain goat and pronghorn antelope residing in the US state of Nevada. Some tissue samples were collected from wild ungulates found dead in the field. Virus neutralizations were conducted with these sera using BVDV1, BVDV2, BDV and PHV strains. PCR, using pestivirus specific primers, was done on serum, tissue and whole blood samples. The resulting amplicons were sequenced and phylogenetic analysis performed to determine pestivirus species. Domestic goats and white tail deer fawn were exposed to PHV by oral/nasal inoculation and observed for clinical presentation.

Results: Phylogenetic analysis showed that PHV is more distant from the recognized species of pestivirus than the recognized species are to each other. Antigenic comparison, using hyperimmune goat serum, demonstrated that the antigenic cross reactivity between PHV and the recognized pestivirus species is low. PHV was detected in mule deer, big horn sheep and mountain goat samples. Serological surveys of pronghorn antelope populations revealed higher titers against PHV than BVDV1 or BVDV2. Clinical presentation following infection of domestic goats with PHV included mild, short-term pyrexia and a decrease in circulating lymphocytes. Infection of white tailed deer resulted in death in 2 out of 6 animals inoculated. Pre-existing antibodies, against BVDV in deer, did not prevent replication of PHV or decreases in circulating lymphocytes. PHV was not transmitted to pen mates following infection of either goats or white tailed deer.

Conclusions: Despite evidence that pestiviruses circulate in wildlife populations, the impact of exposure and prevalence of these infections are largely unknown. The antigenic and genomic differences between classic pestiviruses and the emerging pestivirus PHV suggest that diagnostics designed to detect classic pestiviruses may fail to detect PHV. PHV appears to be replicating in multiple free ranging ungulate populations in the US and may contribute to immunosuppression and death loss in these populations. Further studies need to be done to determine if PHV can be transmitted from wild ungulates to domestic animals.

Btvpur Alsap Vaccines Containing Serotype 4 : Proof of Efficacy for The Control of Btv-4 In Cattle

Claude Hamers¹, Mathieu Chevrier¹, Valerie Frances-Duvert², Sebastien Bernadeau¹, Vincent Badol², Beatrice Tarin², Geraldine Dufaut², Helene Gaude², Sylvain Goutebroze¹

¹Merial, Saint Vulbas, ²Merial, Lyon, France

Objectives: BTVPUR ALSAP is a range of vaccines containing different combinations of bluetongue virus (BTV) serotypes.

In sheep, efficacy of BTVPUR ALSAP vaccines containing BTV-4 is substantiated through an official claim at EU level of 1 year duration of immunity after single shot vaccination.

In cattle, these vaccines have also demonstrated their efficacy under various field conditions but not all scientific data involved is publicly available.

Hereafter we report the outstanding efficacy of a BTVPUR ALSAP vaccine containing serotype 4 against an experimental challenge, under controlled conditions in cattle.

Materials and Methods: Two groups of 6 BTV naïve calves (1 month old) were maintained in an insect-proof facility throughout the experiment.

Group 1 was not vaccinated and served as control.

Group 2 was vaccinated on D0 and D21 with 1 mL of a BTV-4 vaccine formulated at low antigen content.

Twenty one days after second vaccination (ie D42), Groups A and B underwent a BTV-4 virulent challenge.

After the challenge, all animals were monitored for rectal temperature, clinical signs and viraemia (qRT-PCR) over 28 days.

Serological monitoring was performed at key points during the study.

Results: Maximal rectal temperatures after challenge were significantly lower in the vaccinated group (mean: 39.0°C) as compared to the control group (mean: 39.5°C).

Mean daily clinical score was higher in the control group (G1) than in the vaccinated group (G2) on all except one day. To our knowledge, this is the first report of a BTV-4 challenge model inducing clinical signs in cattle.

Interestingly, the peak of clinical scores corresponded to the peak of viraemia.

Viraemia was detected in all controls (high copy numbers), at all time-points after D49 (inclusive). Conversely, none of the vaccinated animals were ever detected positive.

Conclusions: These results demonstrated that vaccination of cattle with a BTVPUR ALSAP vaccine containing serotype 4 provides full clinical and virological protection against a BTV-4 challenge.

These results are comparable to those obtained over the full range of study protocols used and challenges conducted with other vaccines of the BTVPUR ALSAP range in sheep and in cattle and show that BTVPUR ALSAP may be used for bluetongue disease prevention (clinical protection) and for epidemiological control (virological protection) of BTV.

BTVPUR ALSAP is a registered trademark of Merial.

Mycoplasma wenyonii outbreak in a Dutch dairy herd: a case report

Ruben Tolboom¹; Bert van Niejenhuis²; Menno Holzhauser³¹Boehringer Ingelheim, Alkmaar, ²DAP West-Betuwe, Meteren, ³GD Animal Health, Deventer, Netherlands

Objectives: Some cases with clinical signs related to *Mycoplasma wenyonii* have been reported in the Netherlands. This abstract describes an outbreak of *Mycoplasma wenyonii* in a Dutch dairy herd; the pathogen has been detected and identified using the polymerase chain reaction (PCR)/denaturing gradient gel electrophoresis (DGGE) technique.

Materials and Methods: The dairy farm involved had 115 lactating animals. The herd was on pasture during daytime (min. 6h/day) and housed indoors during night-time. No recent changes in feeding had taken place prior to the clinical signs. The cows were fed indoors a mixture of grass silage and maize. The 21st of September 2015 all cows from an age of three months had been vaccinated with a BVD vaccine. No other herd treatments were administered prior to the clinical symptoms. Young calves until an age of 9 weeks, dry cows and lactating cows are housed in the same shed.

Results: Since 15 September 2015 edema of the rear legs (from hock to claw) and udders was observed in a few lactating cows. Affected udders or legs were not painful. The milk production of these cows decreased significantly (50-60%). No clinical mastitis was seen in the udders with edema. At the peak of the outbreak eight lactating cows showed these clinical symptoms. These cows were all born between April 2012 and March 2013 and thereby in their first lactating. The affected cows had no hyperthermia or pyrexia. The 7th of October 2015 blood samples (vacutainer EDTA) of three cows with clinical signs were taken for investigation. A blood smear was made and analysed using microscopy to detect haematropic bacterial parasites, all samples were found negative (GD Animal Health, The Netherlands). The 3rd of November 2015 six blood samples (vacutainer EDTA) for PCR/DGGE testing were taken from the cows with clinical signs at an earlier stage. All these 6 samples tested positive on *Mycoplasma wenyonii* (APHA Weybridge, United Kingdom). Infected cows with clinical signs didn't receive any treatment. The edema of the legs and udders disappeared slowly within two or three weeks and the milk production increased to a normal level in approximately four weeks.

Conclusions: The udder edema, leg edema and milk loss of the cows on this Dutch farm was caused by *Mycoplasma wenyonii*. This pathogen was diagnosed using a PCR/DGGE test. Most reported cases in the Netherlands are based on clinical signs. Needles, ticks or insects can play a role as vector in spreading *Mycoplasma wenyonii*, in this case the symptoms were present before and after the herd vaccination.

Schmallenberg virus sero-surveillance: relationships between herd bulk milk and individual cow blood antibody values in exposed dairy herds

Áine Collins^{1,2}; Michael Doherty²; Jim Grant³; Anne Hallinan⁴; Damien Barrett⁵; John F. Mee¹¹Animal and Bioscience Research Department, Teagasc, Moorepark, Cork, ²School of Veterinary Medicine, UCD, Dublin, ³Applied Physics and Statistics, Teagasc, Co. Meath, ⁴Blood Testing Lab, DAFM, Cork, ⁵Sligo Regional Veterinary Lab, DAFM, Sligo, Ireland

Objectives: The bulk milk ELISA (BM-ELISA) is a useful tool to monitor seroprevalence and exposure to infectious pathogens in dairy herds. However, the relationship between bulk milk antibody values and individual animal blood antibody values in dairy cows naturally exposed to Schmallenberg virus (SBV) is unknown. Hence, the objectives of this study were to determine the correlation between individual animal blood ELISA results and bulk milk ELISA results for SBV and to explore the statistical relationships between BM-ELISA results and individual animal blood ELISA results.

Materials and Methods: Blood samples were collected from 4,047 cows and 24 BM samples were collected from 26 Irish dairy herds. Samples were analysed for SBV-specific antibodies using IDVet ELISA testing kits (serum: Schmallenberg virus Competition Multi-species, ID Screen®; test sensitivity 97.6%, test specificity 100%. milk: Schmallenberg virus Milk indirect, ID Screen®; test sensitivity 96.67%, test specificity 99.05%). The mean herd serological data (skewed) were log (natural) transformed and regressed for both sample/positive (S/P) and optical density (OD) values on BM-ELISA results. The statistical relationships between individual animal blood ELISA results and BM-ELISA results were explored by comparing the estimated distribution function curves (EDF-curve) for individual animal blood ELISA results in each herd, pairwise across herds, using the Kolmogorov-Smirnov statistic.

Results: Twenty two herds were BM-ELISA positive (seroprevalence 29.9-100%) and two herds were BM-ELISA negative (seroprevalence 10.5 and 15.8%) indicating that herds with a negative BM-ELISA result may also have been exposed to SBV. There was a significant relationship between the mean herd seroprevalence and BM-ELISA results (R^2 OD serum-BM OD = 0.72, S/P = 0.69, both $P < 0.0001$) indicating that the BM-ELISA is moderately predictive of mean herd seroprevalence. Of the 325 paired EDF-curve comparisons made across the herds, 79 [24%] had similar EDF-curves and of these, 45 [57%] had contrasting BM-ELISA values (S/P% difference $\geq 5\%$) indicating that herds with similar distributions of individual animal blood ELISA results can have contrasting positive BM-ELISA values. In herds with similar positive BM-ELISA results (S/P% difference $\leq 5\%$) 34 paired herd comparisons were identified of which 28 had significantly different EDF-curves ($0.0466 \leq P \leq 0.0001$) suggesting that herds with similar positive BM-ELISA values can have significantly different distributions of individual cow blood ELISA results.

Conclusions: BM-ELISA values are moderately correlated with herd seroprevalence results and may be a useful SBV surveillance tool in dairy herds. However, this novel exploration of the statistical relationships between individual animal blood ELISA results and BM-ELISA results for SBV adopted in this study indicate that these relationships are not as simple as previously thought.

The detection of severe fever with thrombocytopenia syndrome virus in black goats (*Capra hircus coreanae*)

Jun-Gu Kang¹; Jeong-Byoung Chae¹; Young-sun Cho¹; Yun-Kyung Cho¹; Sung-Suck Oh¹; Do-hyeon Yu²; Kyoung-seong Choi³; Hyeon-cheol Kim

⁴Jinho Park ⁵Bae-keun Park ⁶Young-Hun Jung ⁷Kye-Hyung Kim ⁸Joon-Seok Chae ^{1*}

¹Veterinary Internal Medicine, College of Veterinary Medicine, Seoul National University, Seoul, ²Veterinary Internal Medicine, College of Veterinary Medicine, Chonnam National University, Gwangju, ³College of Ecology and Environmental Science, Sangju, ⁴College of Veterinary Medicine, Gangwon National University, Chuncheon, ⁵College of Veterinary Medicine, Chonbuk National University, Iksan, ⁶Research Institute of Veterinary Medicine and College of Veterinary Medicine, Daejeon, ⁷National Institute of Animal Science, Jeonju, ⁸Division of Infectious Diseases, Pusan National University Hospital, Busan, Korea, Republic Of

Objectives: Severe fever with thrombocytopenia syndrome virus (SFTSV) is a novel bunyavirus and a causative agent of an emerging disease in China, Japan, and the Republic of Korea (ROK) and is mainly characterized by fever, leukopenia and thrombocytopenia in human. To investigate the prevalence of SFTSV in domestic animals, we collected serum from Korean indigenous goat (*Capra hircus coreanae*) that is the indigenous goat of Korea.

Materials and Methods: Sera were collected from domestic black goats (*Capra hircus coreanae*) in the ROK. Using serum samples, SFTSV-specific genes were amplified by one-step reverse transcription (RT)-PCR and nested PCR and sequenced. The sequence data were analyzed using Chromas and were aligned using CLUSTAL X. To assess the relationships between individual pathogens, a phylogenetic tree was constructed using the neighbor-joining method in MEGA6. Monoclonal antibodies (mAbs) against the recombinant nucleoprotein (NP) of SFTSV were generated to develop a competitive enzyme-linked immunosorbent assay (cELISA) for the detection of antibodies against SFTSV infection in the goats.

Results: A total of 687 serum samples were collected from goats (20 in Gwangwon, 31 in Gyeonggi, 25 in Gyeongnam, 13 in Gyeongbuk, 325 in Jeonnam, 130 in Jeonbuk, 4 in Jeju, 325 in Chungnam, and 24 Chungbuk Province). A total 18/687 (2.6 %) samples were positive for SFTSV using RT-PCR targeting the "S" segment RNA. The size of amplified product was 346 bp. The obtained sequences showed 95.4% ~ 99.7% similarity to KP994441 from feral cat in ROK. A total 40/500 (8.0%) samples were positive for SFTSV using cELISA.

Conclusions: SFTSV readily infects humans with farming-related exposures as well as numerous domestic and wild animals. Molecular and serological data further suggest that the SFTSV circulates widely in the Republic of Korea, Japan and China.

Post-epidemic Schmallenberg surveillance: prospective bovine serological and Culicoides virological studies

Áine Collins ^{1,2*} Magda Larska ³ Michael Doherty ² Anne Hallinan ⁴ Damien Barrett ⁵ John F. Mee ¹

¹Animal and Bioscience Research Department, Teagasc, Moorepark, Cork, ²School of Veterinary Medicine, UCD, Dublin, Ireland, ³Department of Virology, National Veterinary Research Institute, Pulawy, Poland, ⁴Blood Testing Lab, DAFM, Cork, ⁵Sligo Regional Veterinary Lab, DAFM, Sligo, Ireland

Objectives: Schmallenberg virus (SBV) was first identified in north-western Europe in 2011. The virus rapidly achieved a pan-European distribution resulting in an epidemic of ruminant abortions, congenital deformities and mild clinical symptoms in adult dairy cattle. There has been limited research investigating whether SBV continues to circulate in previously infected regions. Therefore, the aim of this study was to investigate SBV circulation in dairy herds in 2013 and 2014 following initial exposure to the virus in 2012.

Materials and Methods: Blood samples were collected from 26 dairy herds before and after (spring and autumn) the vector-active period of 2014. Additionally, known SBV *Culicoides* vector species trapped on ten of these farms during the vector active season were analysed for SBV RNA.

In the spring, 5,527 blood samples were collected; 4,047 [73%] cows and 1480 [27%] heifers (12-24 months age). In the autumn 2,444 blood samples were collected; 1,519 [62%] spring-born weanlings (6-8 months old) and a subsample the sero-negative animals identified in the spring (n = 925; 285 cows [12%] and 640 [26%] heifers). Samples were analysed for SBV-specific antibodies using an IDScreen® ELISA kit. Light trapping for *Culicoides* was carried out on ten of the study farms as part of a separate *Culicoides* entomological study (Collins et al, 2015. World Buiatrics Congress). Each site was sampled fortnightly from 21st July to 5th November 2014. One Onderstepoort Veterinary Institute UV light trap was run overnight at each site and catches were transferred into 80% ethanol. *Culicoides* were morphologically identified and pooled according to species and parity status. A total of 138 pools (3,048 *Culicoides*, average 22 pigmented *Culicoides*/pool), from 6 known SBV vector species were tested for SBV RNA. The analysis was based on duplex- real-time reverse transcriptase PCR for the detection of the SBV S segment and the *Culicoides* 18 S gene (*C. obsoletus/scoticus*, *C. chiopterus*, *C. pulicaris*, *C. punctatus*) or the mitochondrial CO1 gene (*C. dewulfi*) as internal control in the in-house optimised real-time PCR system.

Results: In the spring of 2014, animal-level seroprevalence was 61%. Sero-negative animals (38%) were predominantly 2013 spring-born heifers (98%) suggesting they were not exposed to SBV during 2013. Within-herd seroprevalence ranged widely (8.3% to 98%) across herds indicating individual herds had varying risks of new infection in 2014.

In the autumn of 2014, 2,382 (98%) animals were sero-negative and 24 (0.98%) tested positive. Of weanlings, 1,491 [98%] were sero-negative and 9 [0.59%] tested positive. Of the 925 resampled spring sero-negative animals, 891 [96%] animals (268 [29%] cows and 623 [67%] heifers) remained sero-negative and 15 [1.62%] animals (10 cows and 5 heifers) tested positive. The 24 seropositive animals (9 weanlings, 5 heifers and 10 cows) identified in the autumn originated in 14 different herds and the number of seropositive animals in seropositive herds ranged from 1 to 3 animals [0.5-2.8%]. These findings are inconsistent with SBV transmission characteristics. Thus, we suggest that these are false-positive results. Of the 138 *Culicoides* pools examined for SBV RNA one pool (*C. dewulfi*) was weakly positive on initial first test (Ct= 38.11, IC= 19.15) but was negative when re-tested and negative using gel electrophoresis. No other *Culicoides* pools tested positive for SBV RNA suggesting that SBV did not circulate in the *Culicoides* vector during the sampling period.

Conclusions: It is concluded that there was no evidence of SBV circulation in 2013 and 2014 in these Irish herds. However, large populations of naïve weanlings and heifers were identified and these may be at risk of SBV infection in the future should the virus re-emerge; SBV re-emerged during 2014 in Germany. Furthermore, known *Culicoides* arbovirus vectors were definitively identified in these herds suggesting that they are likely have a role in the transmission of SBV and other arboviruses amongst cattle on dairy farms in the future. This is the first study to examine known arbovirus vector species for SBV in Ireland and Great Britain.

Incursion of SBV in Sweden and situation update in Sweden and Finland

Siamak Zohari¹ Gunilla Blomqvist¹ Jan Chirico¹ Ann-Sophie Olofson¹ Katarina Näslund¹ Sara Häggglund² Mikael Juremalm¹ Ilona Laamanen³ Sirkka-Liisa Korpenfelt³ Ulla Rikula³ Anette Bøtner⁴ Jenny Frössling⁵ Erika Chenais⁵ Karl Ståhl⁵ Lena Renström¹ Jean-Francois Valarcher^{2*}

¹Department of Microbiology, National Veterinary Institute, SVA,

²Department of Clinical Sciences, Division of Ruminant Medicine and Veterinary Epidemiology, Swedish University of Agricultural Sciences, Uppsala, Sweden, ³Veterinary Virology Research Unit, Research and Laboratory Department, Finnish Food Safety Authority Evira, Helsinki, Finland, ⁴National Veterinary Institute, Technical University of Denmark, Copenhagen, Denmark, ⁵Department of Disease Control and Epidemiology, National Veterinary Institute, SVA, Uppsala, Sweden

Objectives: The first indication of the presence of SBV in Sweden was demonstrated by the detection of anti-SBV antibodies in a blood sample collected as a part of surveillance program in small ruminants in autumn 2011. One year later a high seroprevalence of anti-SBV antibodies within the Swedish ruminant population were observed indicating a rapid spread of the infection throughout the country. The objectives of this study were to carry out a molecular characterization of SBV circulating in the Swedish ruminant population from November 2012 to the end of May 2013 and to determine the seroprevalence and evidence of exposure to SBV in 2015.

Materials and Methods: Molecular characterization-Between November 2012 and June 2013, tissue samples were obtained from 328 herds including 169 cattle herds, 124 sheep- 4 goat flocks, 2 alpaca- 1 camel- and 1 bison herds in Sweden. Samples of brain were collected from malformed, aborted or cases of stillbirth fetuses submitted for post mortem examination to the National Veterinary Institute in Sweden. The samples were tested initially for detection of SBV RNA using RT-qPCR. Brain tissue specimens were homogenized using a tissue Homogenizer in TE buffer medium and centrifuged briefly. Homogenization of tissues was performed under biosafety level 3 conditions. RNA was extracted from tissue homogenate using a Magnatrix 8000+ robot (NorDiag AB, Hägersten, Sweden) using the Nordiag Vet Viral NA extraction kit (NorDiag AB, Hägersten, Sweden) according to the manufacturer's instructions. Fifteen SBV positive samples were selected on the base of differences in geographic location, timing and animal [bovine (n=6) and ovine (n=9)] species of origin. PCR assay with M and S segments specific primers was performed to amplify the complete open reading frame of the respective gene.

Serological testing-Serological tests were carried out on sera submitted to the National Veterinary Institute as a part of the health control investigation in 2015. Sera from cattle borne after 2013 collected in southern and central Sweden and Finland were analyzed for presence of SBV-specific IgG antibodies. Sera were screened using a commercially available indirect SBV Antibody Kit, following the instructions of the manufacturer.

Results: SBV was confirmed by RT-qPCR in brain tissues from malformed fetuses obtained from 27 cattle- and 33 sheep herds in Sweden. The phylogenetic analysis of the M gene of the selected number of SBV positive animals from Sweden and the inclusion of sequences from Finland, Denmark and Norway indicated multiple introduction and co-circulation of at least 4 sub-clades of this virus at the time of the study. After very wide spread of SBV during the vector season 2012 and 2013, no typical malformation associated to SBV foetal infection in cattle and sheep were reported in 2014 and 2015. Serological data obtained in animals born after 2013 suggest that SBV did not circulate in Sweden and Finland in 2014 and 2015.

Conclusions: SBV has been considered endemic in Sweden since June 2013 and therefore no further surveillance activities or clinical investigations have been performed. Although SBV is still circulating in several European countries including The Netherlands, Belgium and Germany, no pathological (acute clinical manifestations or an increased number of malformations), virological or serological evidence of current circulation of the virus have been reported in Sweden since 2013. The consequences for future epidemic in Nordic countries will be discussed.

P02-002-085

Schmallenberg virus seroprevalence in domestic ruminants in Poland between 2013 and 2015.

Magdalena Larska^{1*} Julia Kęsik-Maliszewska¹ Jan F. Żmudziński¹

¹Department of Virology, National Veterinary Research Institute, Puławy, Poland

Objectives: Schmallenberg virus (SBV) affects animal husbandry mostly by causing congenital abnormalities in cattle, sheep and goats. Morbidity and mortality of less than 3% were reported. In adult animals, clinical signs are mild and may pass unnoticed. In Poland, the impact of SBV remains underestimated, since despite that the disease is not registered, the notification of an outbreak would cost a farmer a problem of epizootic restrictions. SBV has spread to Poland in 2012 infecting only some 2% of ruminant population. After SBV overwintering, the virus infected further 30% of animals in 2013.

Materials and Methods: Serum sampling was carried out during national bluetongue virus (BTV) monitoring program. In order to detect an individual SBV seropositive animal, the numbers of samples were calculated using county population statistics estimating 20% seropositivity with 95% confidence level. A total of 14.350 samples from cattle, sheep and goat were collected from July 2013 to May 2015 from 14 out of 16 Polish provinces. Commercial multi-species ID Screen Schmallenberg Virus Competition Test (Montpellier, France) was used to detect anti-SBV nucleoprotein antibodies. Statistical analysis was performed using STATA v. 13.0 software (StataCorp LP, Texas, USA). The prevalences were corrected by the population probability weights (pweights) calculated as follows: 1/(n of sampled animals/N of animals in the province). The associations between the species, gender, age, province, year, domestic ruminant densities per km² and SBV seroprevalence were estimated using χ^2 , Spearman test and odds ratio (OR) calculated by univariate logistic regression. The risk factors of SBV seropositivity were assessed using mixed-effects logistic regression model built accounting for possible clustering and collinearity.

Results: The overall seroprevalences were 35.4%, 58.7% and 29.5% in 2013, 2014 and 2015, respectively. The testing of the samples from 2015 was not finished by the time the abstract was prepared, therefore the possible different outcome should be considered. The association between the province of origin and SBV seroprevalence was significant in 2013 and 2015. The province seroprevalences in 2014 were comparable suggesting even spread of the virus among domestic ruminants. The increase of the percentage of SBV seropositive animals in the provinces (15.3% on average) between 2013 and 2014 was significant especially in the southern provinces. The seroprevalence decline at the province level between 2014 and 2015 was 28.2% on average. In all tested years the highest seroprevalence was found in cattle (57.8%), while it was lower in smaller ruminants (23.3% goats; 39.1% in sheep). The risk factors for the SBV seropositivity were animal age (SBV seroprevalence

decreased with age), gender (females were 0.4 times more likely to be seropositive than male), species (highest seroprevalence in cattle, lower in small ruminants), year of sampling, ruminant densities and province.

Conclusions: The SBV transmitted to Poland in 2012 continued to spread in 2013 and 2014, reaching the peak seroprevalence in 2014. In 2015, the seroprevalence started to decline, however the data is limited. The dependence between SBV seroprevalence and age may be explained by the differences in the exposure time, while the differences among different species may be due to species susceptibility, vector feeding preferences or maintenance. Even SBV geographic distribution and appearance of the virus in the midges collected in different locations scattered in the country may suggest local virus circulation, however at a low level.

Experimental Infection Of Rabbits With Bovine Herpesvirus 5 (BoHV-5)

Helio Martins De Aquino Neto ¹; Elias J. Facury Filho ²; Edel F. Barbosa-Stancioli ³; Antônio U. de Carvalho ²; Milene A. Rachid ⁴; Aline A. Silva Barbosa ³; Iracema L. Quintinho-de-Carvalho ³; Fabia S. Campos ⁴; Rosa M. Esteves Arantes ⁴

¹Universidad del Tolima, IBAGUE, Colombia, ²Clínica e Cirurgia Veterinárias, ³Laboratório de Virologia Básica Aplicada, ⁴ICB, Universidade Federal de Minas Gerais, Belo Horizonte, Brazil

Objectives: Bovine Herpesvirus 5 (BoHV-5) is an alphaherpesvirus associated with neurological disease and meningoencephalitis, usually a fatal viral infection and highly prevalent in South America. Usually, the neurological signs observed in BoHV-5 infections are multifocal deficits and comprise mainly cerebral and brainstem dysfunctions. This study aimed to characterize the clinical, histological and location of the virus in the central nervous system, in rabbits inoculated with a Brazilian strain of BoHV-5 named Mutum, isolated from a five years old cow with spinal cord symptoms, a rarely reported signal for this disease.

Materials and Methods: Six animal inoculations were performed to evaluate the susceptibility of rabbits to a Brazilian strain of BoHV-5. Weanling New Zealand rabbits were intranasally inoculated with 5×10^7 TCID₅₀ of virus suspension into each nostril and two animals were mock-infected. The rabbits were clinically monitored and blood samples and nasal swabs were collected. Half of the animals was euthanized 5 days post inoculation (pi) and the remaining, in the 12th day. Sections of brain, cerebellum, brainstem, trigeminal ganglia and spinal cord were collected for virological and histological examinations.

Results: The inoculation of weanling rabbits caused neurological disease 50% of infected animals. Until the first six days after inoculation, some animals showed occasional sneezing, beyond nasal and ocular discharge. Other rabbits showed seizures, periods of depression or excitability, tremors crisis (Jackson's seizures), nystagmus and circling, started on the day 6 pi. One of these animals showed a paresis of the hind limbs. Infectious virus was recovered by isolation from cortex, cerebellum, trigeminal ganglia, cervical, thoracic and lumbar spinal cord of infected animals. Viral DNA was detected in the brainstem, cerebellum, cervical spinal cord and thoracic spinal cord of infected animals.

Conclusions: These results confirm the BoHV-5 ability to induce medullary syndrome with ataxia of pelvic members preceding cerebral involvement and highlight the relevance of pointing out these symptoms during clinical evaluation of cattle.

Emerging Diseases

P02-002-087

Towards understanding the increasing threat of digital dermatitis treponemes.

Nicholas Evans ¹; Simon Clegg ¹; Stuart Carter ^{1*}

¹University of Liverpool, Liverpool, United Kingdom

Objectives: There is now considerable evidence identifying treponemes as the primary causative agents of bovine digital dermatitis (DD), a worldwide infectious lameness of dairy cattle. We have been able to demonstrate these DD treponemes are also implicated in additional, more recently reported infectious lameness in sheep, beef cattle, Wild American Elk and goats. We have also demonstrated treponeme contribution to bovine non-healing hoof lesions and hock lesions.

This study set out to investigate the genetic relationships of DD treponemes from a range of hosts using a multi locus sequence typing (MLST) analysis.

Materials and Methods: The cultivable DD treponemes have previously been classified into three phylogroups, based on 16S rRNA gene similarity to human treponeme species and by which they are frequently referred as '-like': Treponema medium-like, Treponema phagedenis-like and Treponema denticola-like, with the latter recently taxonomically designated as Treponema pedis.

The fastidious nature of these important spirochetes previously precluded studies investigating within phylogroup genetic diversity. An archive of treponemes isolated by the authors here enables MLST to quantify diversity and potential transmission events of DD treponemes. Isolates (n=118) were obtained from different animal hosts (including dairy and beef cattle, sheep, goats and Wild American Elk) representative of nine countries and three continents. Implementing the MLST for these bacteria included PCR and DNA sequencing of seven different housekeeping genes from all isolates, and subsequently comparing them using a range of phylogenetic analyses.

Results: The seven different housekeeping genes were sequenced for each isolate and demonstrated low level diversity between strains for each phylogroup. The allelic profiling allowed the typing of strains from the variety of hosts and showed that all animals can be infected with very similar bacteria, with some animals identified as likely infected with the same bacteria. Human treponemes, whilst displaying novel allelic profiles, still only differed by a small number of nucleotides substitutions when compared with from animal isolates.

Bacterial sequence types (ST) were shared across worldwide geographic regions and different hosts in several cases. Other ST's appeared to transmit around a farm, infecting multiple animals on one farm, whereas others infect multiple hosts in similar geographical areas, suggesting between host transmissions. Of the three phylogroups T. pedis was the most variable, with lower levels of diversity seen in the other two phylogroups.

Conclusions: Human and animal treponeme similarity suggests these phylogroups may have been transmitted between man and animal at some point. It might be considered DD treponemes are not readily differentiated by MLST. However, that identical STs were shared between isolates between animals on the same farm and from different host species in similar geographic regions suggests that bacteria can spread between animals on a farm, and between host species. The expanding host and tissue range of DD treponemes requires vigilance given the substantial animal welfare issues, lost productivity and costs towards treatment and control of associated diseases.

Schmallenbergvirus in Sheep: Persistence of Antibodies after Infection

Ursula Domes¹ Benjamin Bauer¹ Britta Janowitz¹ Jens Böttcher¹¹Bavarian Animal Health Service, 85586 Poing, Germany

Objectives: After the appearance of Schmallenbergvirus various studies were performed. But few studies were made about the persistence of antibodies after infection. Especially in sheep there are nearly no data on duration of immunity. The data in cattle suggest that immunity last for at least one year following natural infection.

Materials and Methods: In this study sheep from two herds were included, one herd in northern Bavaria with 400 animals and one in the south with 800 ewes. Several blood samples of individual animals of different ages were taken. 106 sheep from the northern herd and 90 from the southern herd were followed individually. The samples were analyzed with the ELISA Test "Schmallenberg ID Screening". The first herd was tested three times between January 2013 and February 2014. In the second herd six samples were taken between February 2012 and May 2014.

Results: The northern herd was included later in the study, with already seroconverted animals. But 62 sheep from the 106 animals were seronegative during the whole study and 15 animals were seropositive in every sample. Six animals were positive in two samples, 7 only in the first sample and afterwards they were negative.

The samples in the southern herd were first taken in February 2012, were nearly all 55 animals were seronegative, only one animal was positive and stayed positive in all samples during the two years. 41 sheep seroconverted between May 2012 and August 2013 and stayed seropositive until April 2014. In August 2013 20 yearlings were tested, all negative in the four following samples. Also the 15 new yearlings of Mai 2014 were negative.

Conclusions: These samples showed that antibodies against Schmallenbergvirus can persist for minimum two years following natural infection in sheep. Individual animals were tested and individual durations of antibodies could be shown, with variations from several months to two years. It can only be estimated that these antibodies are protective against illness, because in the year 2014 there were very few cases of Schmallenbergvirus in Bavaria. The herds are followed up during the next months.

Are potentially toxigenic Clostridium spp. (especially Clostridium botulinum) a significant factor for chronic health problems in dairy herds?

Johanna Dietsche¹ Moritz Metzner¹ Carola Sauter-Louis¹ Rolf Mansfeld¹Martina Bechter¹ Gabriela Knubben-Schweizer¹ Ute Messelhäuser²Stefan Hoermansdorfer³ Martina Hoedemaker⁴

¹Centre for Clinical Veterinary Medicine, LMU Munich, Clinic for Ruminants with Ambulatory and Herd Health Services, ²Bavarian Health and Food Safety Authority, Laboratory of Food Microbiology, ³Bavarian Health and Food Safety Authority, Laboratory of Veterinary

Microbiology, Oberschleissheim, ⁴University of Veterinary Medicine Hannover, Foundation, Clinic for Cattle, Production Medicine Unit, Hannover, Germany

Objectives: In recent years, unusual herd health problems in dairy cattle have been reported by veterinarians and farmers across Germany that manifested as chronic suffering with severely decreased milk yield and significant losses up to complete abandonment of herds. According to reports, Clostridium botulinum and/ or its toxins and/ or antibodies were detected in affected animals. The authors of these reports named this previously unknown form of botulism "chronic/ visceral botulism", and – in contrast to classic botulism – thought it to be caused by toxicoinfection.

Materials and Methods: In a case-control study across Bavaria, Germany, herds in the case group (n=21) had to meet at least three of the following criteria: a decrease in milk production of more than 15%, more than 5% of animals euthanized or dead within the last twelve months, a culling rate higher than 35%, recumbency in more than 10% of animals, and an increased disease rate. Herds in the control group (n=10) were not allowed to meet any of these criteria. A total of 1720 dairy cows were included in the present study of which 284 (case and control cows) were examined further. After passing a standardized clinical examination, the animals were sampled for bacteriological, parasitological, serological and hematological examination. Questionnaires were used for additional data collection and covered specific fields within each farming enterprise.

Results: Analysis of fecal and rumen fluid by real-time PCR revealed, that Clostridium spp. were present on 74.2% of the dairy farms evaluated. There was no difference in the frequency of detection between the case and the control group or between the case and control cows on each farm. Species of Clostridium were distributed as follows: Clostridium perfringens 72%, Clostridium novyi 24%, Clostridium botulinum 3%, and Clostridium haemolyticum 1%. Serum antibodies against BoNT-C1 and -D were detected in 78.2% of the farms with no statistically significant difference between the case and control group. However there was a statistically significant difference between the cows within the case group (84.6% positive - control cows versus 70.2% - positive case cows). Cows in the case group were significantly dirtier, skin lesions on bony prominences of the body proximal to the carpus/ tarsus were significantly more often detected and prevalence and severity of lameness were significantly higher than in the control group.

Conclusions: The data analysis showed a significantly lower hygiene and a significantly higher prevalence of lameness and skin lesions in the case group than in the control group. However, there was no correlation found between any of these factors and the frequency of detection of Clostridium Species.

Emerging Stealth Assault by Mycoplasma bovis in Sucklers in Pakistan

Mudassar Iqbal¹ Riaz Hussain¹ Muhammad Shahzad¹ Fazal Mahmood² Ahrar Khan²

¹University College of Veterinary and Animal Sciences, The Islamia University of Bahawalpur, Bahawalpur, ²Department of Pathology, University of Agriculture, Faisalabad, Pakistan

Objectives: *Mycoplasma bovis* is one of the components of the bovine respiratory disease complex (BRD), which is mainly characterized by

pneumonia. The BRD complex inflicts considerable financial losses worldwide. Variable prevalence of *Mycoplasma bovis* infection has been reported in small and large ruminants around the world. However, no information is available regarding pathophysiology of this microorganism in dairy cattle of Punjab, Pakistan. Therefore, present study was conducted initially to investigate this organism hideout in a local dairy herd.

Materials and Methods: The present study was conducted to investigate the pathology of *Mycoplasma bovis* infection in local, 2-4 week-old *Bos indicus* dairy calves. In a herd of 50 calves, 15 (30%) became sick and 5 (10%) died soon after transportation which were subjected to necropsy. PPLO broth and agar plates were inoculated with nasal swabs from clinically sick calves and pus samples from abscesses. These were incubated at 37 °C with 5% CO₂ for 7-10 days and monitored for fried egg colonies. Furthermore, molecular identification of *Mycoplasma bovis* was done to confirm the occurrence of *Mycoplasma bovis* in dairy calves.

Results: Clinical signs included respiratory distress, lameness and swollen joints. During postmortem examination, severe suppurative polyarthritis and fibrinosuppurative tenosynovitis were observed. The knee and stifle joints were most severely affected. Otitis media was a common feature in all necropsied calves. Multiple abscesses with caseous exudate were present in cranioventral lobes whereas dry necrotic cavities in diaphragmatic lobes of the lungs. Microscopically, synovial cavities and membranes of the joints exhibited multiple foci of central liquefactive necrosis surrounded by lymphocytes, plasma cells and macrophages, with peripheral fibroplasia. Immature abscesses were exhibiting infiltration of neutrophils. In the lungs, multiple well circumscribed abscesses were minimally calcified. *Mycoplasma bovis* infection was confirmed by PCR.

Conclusions: In conclusion the finding of the present study indicated that *Mycoplasma bovis* infection is a serious threat to the dairy animals in Pakistan. In addition to any economic consequences associated *Mycoplasma bovis* must be considered significantly important and further studies are required to reduce the economic losses in dairy cattle of Punjab, Pakistan.

An evaluation of the potential of text analytics to a Veterinary Pathology and Surveillance Service

Ronan Oneill¹; John Moriarty²

¹Virology, ²Pathology, DAFM Labs, Celbridge, Ireland

Objectives: Animal health surveillance should constantly reinvent both the sources of data and the modes used to analyse it. Pathology is a versatile discipline well positioned to detect emerging and changing animal disease. Traditionally, pathology services categorise case-loads using frameworks and classifications agreed a priori. However modern IT systems enable very large datasets to be iteratively re-analysed in real time. This report objectively analyses a very large free-text veterinary pathology database, to test the advantages and added value obtained by treating such a highly technical source simply as an extremely rich text mine.

Materials and Methods: The period chosen for analysis was 24 months: 1st Jan 2010 to 31st Dec 2013. The Irish Veterinary Laboratory Service LIMS system database was interrogated on 22/02/15 and an extract obtained. The dataset consisted of 75, 047 pathology reports (clinical,

post-mortem and histology) with a total of 2,165,565 words covering submissions from all six Regional Veterinary Laboratories (RVL).

The dataset was filtered to retain only submissions related to bovine animals and common link words such as “the, and, of, with, a”, etc, were removed from further inclusion.

The analysis tested both submissions and individual words in terms of geo-location, month, frequency, etc and also examined cross-links with other clinical submission data available.

Results: The average number of words per submission was 29.5, with relatively little seasonal but some minor RVL effects detected.

The commonest pathology terms were pneumonia, congestion, oedema, diffuse and enteritis with frequencies of 5984, 5693, 5229, 4233 and 4198 respectively. In contrast, the words infarct, dermatitis, cirrho, bullous and malacia had frequencies of 82, 64, 61, 58 and 52 respectively. The histological partial terms infiltrat, monocy, macrophag, lymphocy, eosinoph and basoph recorded frequencies of 409, 271, 249, 229, 137 and 31 respectively.

The words enteritis and pneumonia had marked frequency peaks between February and May each year while hepatic and nephrosis recorded no seasonality. The word Dictyocaulus had a clear frequency peak between July and November, while Fasciola had a pronounced trough in June and July. Further analysis demonstrated distinct patterns of word frequency associated with particular cattle age groups and particular months with graphical demonstration most effective.

Conclusions: Pathology services produce unique flows of expert opinion and highly detailed intelligence on disease diagnosis and effects which are ideally suited to text mining techniques. Such data sources are independent of diagnostic techniques and could operate near real-time or be automated to trend accessibly based on frequency. A text analytics approach requires no prejudice, maximises flexibility and has significant training potential. Best of all, it allows pathologists to concentrate on pathology without the overhead of classification.

Genotypic Variation Of Coxiella Burnetii In South-West Dairy Farms In The Uk.

Thomas Chisnall^{1*}

¹School of Veterinary Science, University of Bristol, Bristol, United Kingdom

Objectives: Over the last 10 years research into the zoonotic disease Q Fever, and the causative bacteria *Coxiella burnetii*, has increased considerably. This increase is mainly as a result of the large-scale outbreak in The Netherlands from 2007 to 2009. Human infections are primarily due to exposure to infected ruminants, particularly around parturition. This poses a threat to farm workers and veterinarians. Whilst infected goats have been attributed as the primary cause of the Dutch outbreak, dairy cattle are still considered a potential reservoir for the spread of this disease.

Materials and Methods: Through bulk tank milk analysis, using qPCR, *C. burnetii* has been found in South West dairy farms at a herd prevalence of 69.7% (108/155). We wanted to investigate the molecular epidemiology of these samples by determining if the genotype was related to *C. burnetii* found in Europe.

Multiple Locus Variable number tandem repeat (VNTR) Analysis (MLVA) has been shown to be a viable genotyping assay for *C. burnetii*, as devised by Arricau-Bouvery et. al, although some modification was required to detect organisms from Bulk Tank Milk (BTM) samples. We aimed to utilise this assay for the positive BTM samples, by selecting a sub-set of primers which are able to differentiate UK strains of the bacterium.

The size of the VNTR alleles is converted to units, with clustering analysis on these units. Clustering analysis is by Unweighted Pair Group Method using Arithmetic averages (UPGMA).

Results: Initial analysis has led to the possibility of multiple genotypes being identified in single BTM samples. For a number of samples, more than 1 PCR product was visualised following gel electrophoresis. These additional PCR products were larger than from other samples, indicating that additional tandem repeats were present. Full MLVA analysis utilising capillary gel electrophoresis to determine exact amplicon length is still ongoing. These genotypes are being compared to those found in the rest of Europe, in both dairy cattle and small ruminants from a collaborative MLVA dataset. This

Conclusions: As this investigation is still ongoing, it would be premature to draw any confident conclusions. Once completed, knowledge of the MLVA genotypes present in the UK will be of interest to European peers researching this bacteria. To our knowledge, this only the 2nd time *C. burnetii* has been genotyped in the UK and the first time in UK dairy cattle.

P02-002-093

Our experience with Lumpy Skin Disease epidemic in Greece in 2015

George Christodoulopoulos^{1,*}

¹Clinical Veterinary Medicine, School of Veterinary Medicine - University of Thessaly, Karditsa, Greece

Objectives: Lumpy Skin Disease (LSD) is an acute viral disease of cattle that is endemic in most of Africa and Middle East. In August 2015, LSD was first time spread to Greece with the epidemic starting from the border with Turkey. This is a report of the infection epidemic in respond to the Greek State received measures; also includes our clinical experience with a limited number of animals diseased. At the time of writing this abstract, the epidemic event is continuing.

Materials and Methods: In the suspected cases, the disease was confirmed by real-time PCR in heparinized total blood. Analysis was carried out in the Athens Veterinary Center (National laboratory).

In face of the epidemic, the Greek State implemented an extensive stamping-out policy, zoning and movement control inside the country. Emergency vaccination campaign of all cattle against LSD was progressively applied in the regions of the outbreaks. The vaccination was completed in the entire Evros regional unit up the middle October 2015; while the vaccination is still in progress (end of November 2015) in the entire Xanthi, Rodopi and Kavala Regional Units.

Results: Up to the middle of November 2015, one hundred four (104) infected farms had been confirmed and the infection had been spread southern to the central Macedonia, in the Regional Units of Chalkidiki and Thessaloniki, and in the Limnos Island. In the infected farms a number of

474 cattle had been found clinically diseased and 5,161 heads had been destroyed during the implementation of the stamping-out policy.

A number of the cattle clinically affected brought to our attention. Clinical signs initially included lachrymation, fever (>40.5 °C), loss of appetite, and disinclination to move. Approximately one week after the initiation of the fever, nodules were appeared at all over the body and swelling of the superficial lymph nodes. The diameter of the nodules was 0.5 to 1.5 cm, size relatively small in comparison with the description of the literature (2.0 to 5.0 cm). At the time of skin nodules appearance, soft yellow-grey nodules and ulcers were occurred in the mucous membranes of the mouth, nose, respiratory tract and the genital tract. Salivation, nasal discharge and corneal opacity were frequently seen. All cases were destroyed within the first days of nodules appearance and stages of nodules that exude serum, break away, form scabs and excoriate were not seen.

Conclusions: The stamping out policy in combination with vaccination was proved a useful tool for the control of the infection. However in the case of the described epidemy a delay of the vaccine application was noted due to unavailability of the vaccines. This delay of vaccination contributed to the disease spread. Other causes of disease spread were the high temperatures till the end of November 2015 and the illegal livestock moves.

IBR and BVD prevalence in President Epitácio and Mirante of Paranapanema settlements, São Paulo, Brazil.

Mario Reyes¹* Bruno M. Ribeiro¹ Natalia C. Gaeta¹ Claudia P. Ribeiro² Eduardo C. Marques¹ Lilian Gregory¹

¹Clinic Medical, University of São Paulo, ²Virology laboratory Cattle, Biological Institute of Sao Paulo, São Paulo, Brazil

Objectives: The purpose of this research is conducted clinical assessment and establish the regional prevalence of IBR and BVD, by studying the dairy cattle herds of micro settlements of President Epitacio and Mirante de Paranapanema cities.

Materials and Methods: The settlement belonging to the region of President Epitacio and Mirante do Paranapanema cities that have approximately a total of 917 settlers and 17,934 cows distributed among them. Milk production of these settlers come to 14,980,919 liters of milk, the main economic activity of this regions. 1. -To select the number of animals and properties to our collection to take a prevalence of the presence of IBR and BVD, 50% were choosed animals and 10% in the properties, with a confidence level of 95% and a specificity and a sensitivity of 80% , in properties with 1 to 200 animals. Obtained this calculation were selected 41 properties and 4 cows per property. 2. – On each cow became an clinical examination of the genital system through an obstetric examination (rectal palpation) and gynecological examination (vulva external inspection, vaginoscopic exam to observe the format, color and opening of the cervix) by Grunert, 1994 methods. 3. - approximately 10 ml of blood were collected and was separated non-haemolysed serum. Serum was stored in a cooler at a temperature of about 4 ° C until their arrival at the laboratory. The serum was tested with the serum neutralization techniques for BVD and IBR like described by Pituco et al. 1994 and 1996.

Results: For a better understanding of our results, we used the statistics program Minitab 2015. Of the 168 samples collected in Mirante do Paranapanema and Presidente Epitácio settlements, São Paulo, Brazil, 116 were positive in the serum neutralization test resulted in one prevalence of 69,04% for IBR. These same 168 colected samples, 97 were positive in the serum neutralization test, resulted in a prevalence of 57.73% for BVD. The results show that the both regions studied have presence of IBR and BVD virus and we found abortion in this same region in animals who not receive vaccine for control these diseases.

Conclusions: We can conclude that the prevalence of IBR and BVD in President Epitácio and Mirante do Paranapanema settlements is high, 69,04% and 57,73%. This results was the first established for the State of São Paulo settlements and we have to achieve this problem and helping the settlers to receive more information about these diseases and how they can eliminated this problem in their herds.

An online calculator for assisting in the design of herd-level prevalence surveys whilst taking into account test imperfections

Andrew Duncan^{1,2} George Gunn² Harriet Auty² Roger Humphry²

¹Inverness College UHI, ²SRUC Epi Unit, Inverness, United Kingdom

Objectives: Most practitioners in epidemiology will be familiar with the fact that calculating sample sizes for surveys is often an iterative process due to there being more than one adjustable variable. This is especially so in veterinary epidemiology of livestock because we may have more than one stratum at which to sample - namely animals within herds and sampling the herds themselves. Our online calculator adopts a relatively simple method (Humphry et al., 2004) for the question of determining the number of animals and the number of herds to test in order to achieve a desired confidence about a measured herd level prevalence.

Materials and Methods: For this calculation there is a trade-off between the number of animals in the herd and the number of herds to be tested. This trade-off is hard to explore without testing various different scenarios. Our calculator presents a suite of scenarios via simple 2-D graphs so as to assist the practitioner in “exploring the options” more holistically than is done using the more conventional style of calculator which gives a single result for a single scenario. The calculator was built using the statistical software R (CRAN, 2015) and the Shiny server software produced by RStudio (RStudio, 2015).

Results: Our poster briefly describes the method in the black box alongside screen shots of the calculator with accompanying interpretation in order to demonstrate its utility.

The calculator itself can be accessed for free and the output can be downloaded as a csv file for those wishing to say their analysis. The graphical output contains additional information for users allowing us to display more than just two output variables. Users can change parameters and so get results for their own sample size questions.

Conclusions: The calculator is available here – <https://epidemiology.sruc.ac.uk/apps/>. It should be useful to any practitioner seeking to make an informed decision on sample sizes within and between flocks/herds when designing a herd prevalence survey using an imperfect test.

Identification, Antimicrobial Resistance And Rapd Profiles Of Staphylococcus Aureus From Bovine Mastitis In Ningxia, China

Wang Dong¹* Han Bo² Zhou Xuezhong¹ He Yulong³ Yong Changfu⁴ Shen Mingliang⁵

¹College of Life Science, Ningxia University, Yinchuan, Ningxia 750021, ²College of Veterinary Medicine, China Agricultural University, Beijing 100193, ³College of Life Science, Zhejiang Sci-Tech University, Hangzhou, Zhejiang 310018 , ⁴Animal disease prevention and control center of Shapotou District, Zhongwei, Ningxia 755000, ⁵Agriculture and animal husbandry bureau of Shizuishan, Shizuishan, Ningxia 753000, China

Objectives: The objective of this study was to isolate and identify Staphylococcus aureus (S. aureus) from bovine mastitis in Ningxia, China, to evaluate the antimicrobial resistance, and also to investigate genotypes of the isolates.

Materials and Methods: A total of 327 milk samples were collected from bovine mastitis cases, streaked onto culture media, and then the

isolates were identified by microbiological and biochemical methods. 16S rRNA sequence of *S. aureus* was used for the isolates identification of the polymerase chain reaction (PCR). The antimicrobial susceptibility tests of the isolates were performed by disk-diffusion agar method and a total of 24 antimicrobial agents were used to evaluate the antimicrobial resistance. The genotypes of isolates were investigated by randomly amplified polymorphic DNA (RAPD) and Bio-Numerics analysis software was used to do cluster analysis of the isolates.

Results: The results showed that a total of 35 isolates coming from 10 dairy farms were found to be positive for *S. aureus* by morphological and biochemical methods, in which 5 isolates were from clinical mastitis and 30 isolates came from subclinical mastitis. Furthermore, the results of 16S rRNA suggested that the target fragment of 1551 bp was amplified from all of the 35 isolates respectively. Therefore, the biochemical test results of *S. aureus* were entirely consistent with the molecular identification results of 16S rRNA. The *S. aureus* isolates displayed differences in the antimicrobial resistance. The isolates were resistant to penicillin G, ampicillin, erythromycin, azithromycin, tylosin, streptomycin, clindamycin, lincomycin, doxycycline, sulfadiazine, and sulfamethoxazole. However, all of them were susceptible to amoxicillin, cephalothin, cefradine, amikacin, neomycin, florfenicol, ofloxacin, norfloxacin, ciprofloxacin, and enrofloxacin. The RAPD assay showed that 35 *S. aureus* isolates were divided into 6 genotypes, in which genotype I contained three isolates, genotype II included one isolate, genotype III was composed of 13 isolates, genotype IV had two isolates, genotype V consisted of 4 isolates, and genotype VI had 12 isolates. The most prevalent genotypes of *S. aureus* in Ningxia area were found to be genotype III and genotype VI. There was significant variation in the genotypes of *S. aureus* isolates from various dairy farms.

Conclusions: It was concluded that 35 *S. aureus* isolates were confirmed and divided into 6 genotypes on the basis of RAPD, and the data showed that genotype III and genotype VI were more prevalent in Ningxia area of China. It came to the conclusion in the current study that *S. aureus* showed different antimicrobial susceptibility and resistance against various antibiotics. Therefore, it is recommended to vaccinate the animal against the genotype III and VI of the *S. aureus* for control and prevention of bovine mastitis.

National plan for tuberculosis eradication. Case study in a district of northern Sardinia

Francesco Sgarangella¹*Sergio Masala¹Vincenzo Floris¹Daniela Marongiu¹Giuseppe Bitti¹Bastianina Mossa¹Pietro Desini¹Salvatore Canu¹

¹Department of Prevention, Animal Health Service of ASL Sassari, Sassari, Italy

Objectives: After few cases of bovine tuberculosis (TB) caused by *Mycobacterium bovis* (Mb) recorded in 1998 in Sardinia, in 2007 the Local Health Veterinarians (ASL) of the Province of Sassari revealed many TB outbreaks, with an increased incidence in the area of Goceano, a district which includes 11 municipalities. The objective of this study is to present the result of the TB plan in Goceano since 2007.

Materials and Methods: The area Goceano is approximately 482 km² with about 10.000 cattle bred in 511 farms. A number of risk factors were identified: issues in the system of cattle identification; fragmentation of farms; common use of public pastures resulting in promiscuity among cattle of different farms and between cattle and wild boars; limits of Tb testing with IDT-bovis. To reduce the risks a number of solutions were adopted; 1) the integration of intra-rumen electronic transponder with the ear tags commonly used. 2) geo-referencing of common grassland and farm premises using dedicated software which allowed traceability of all animal movements. The Geographic Information System (GIS) software provided daily updated maps showing the actual number and identification of bovines. 3) Improving the specificity of the TB testing with IDT-bovis, in addition, Gamma-Interferon was used in all cattle over the age of 6 months. TB testing was intensified with tests every six months. All cattle IDT-positive or borderline at the Gamma-Interferon were slaughtered (about 1000 animals). The carcasses were inspected, lesions and lymph nodes sent to the reference laboratory (IZS of Sardinia). All cattle leaving farms were Tb tested. Wild pigs were used as bio-indicators of the state of contamination of the territory from *M. bovis*.

Results: From 2007 to 2012, the local health veterinarians highlighted and denounced 75 Tb (*M. bovis*) outbreaks in the province of Sassari, 90% of those were in the district of Goceano. All cattle underwent Tb testing, with corrective actions taken promptly, including; tightening of controls by vets, using additional diagnostic tests, employing an innovative information system that made possible to identify, track and trace effectively cattle, therefore improving the effectiveness and efficiency of the veterinary service.

The prevalence of outbreaks, in the province, has steadily declined, from 2.4% in 2007 to 0.10% in 2012. Outbreaks gradually withdrawn until December of 2010 when only 3 were notified. In 2013 and 2014 cattle were Tb tested only before movements, still obtaining a reliable health status of herds. In 2015 all cattle underwent Tb testing no outbreaks were notified.

Conclusions: Corrective actions have allowed the recovery of *M. bovis* in the territory of Goceano. The limits of the test IDT imposes strict health measures which remain in the province. The recent Ministerial Decree of 28 May 2015 reiterated the importance of the traceability of all bovines movements allowed by the electronic identification and the need for effective and rigorous health checks both on farms and in slaughterhouses. It is vital to continue to monitor the wildlife as a bio-indicator of the contamination of a territory by *M. bovis*.

P03-003-070

Johne's disease and Bovine Viral Diarrhea bulk milk surveillance in the Western U.S. - regional prevalence and positive farm characteristics

David Wilson¹*Kerry A. Rood¹Chelsea Whitehouse¹Jennifer Bunnell¹Gregory M. Goodell²Todd M. Byrem³

¹Animal, Dairy and Veterinary Sciences, Utah State University, Logan, ²The Dairy Authority, Greeley, ³Antel BioSystems, Lansing, United States

Objectives: Testing for Johne's disease (JD) and Bovine Viral Diarrhea virus (BVD) in dairy herds in Utah and southern Idaho was performed with the major objective of estimating regional dairy herd-level prevalence. Secondary objectives were: for JD, evaluation of changes in individual herd test status compared with previous regional surveillance; estimation

of sensitivity of a single bulk tank milk test for detection of each disease; evaluation of dairy herd characteristics and farm management practices for farms test-positive for either or both diseases.

Materials and Methods: Field personnel from the 2 main milk buyers in the study area collected signed participation forms from producers. Duplicate milk samples were collected by milk haulers at 3-4 day intervals on each of 5 dates from each bulk tank on participating farms. Samples were coded for anonymity, frozen (-20° C), and one sample was shipped to Antel BioSystems for Mycobacterium avium subsp. paratuberculosis, the JD agent, testing with both ELISA and quantitative real-time PCR. The other paired sample was shipped to The Dairy Authority for BVD testing with real-time reverse transcription PCR. Because the tests have nearly 100% specificity, true positive herd status for each disease was defined by finding at least one tank sample test-positive. Sensitivity was defined as the total number of positive test results for each agent divided by the total number of tests performed on all bulk milk samples from the herds true positive for that agent.

Farms positive for JD or BVD were contacted through the milk buyer using their number code and offered a follow up program. If they agreed, their identity was released to the investigators. A questionnaire developed and used for previous projects was slightly modified to evaluate farm management practices and characteristics associated with JD and BVD. Initially, 6 farm visits were made by all 4 field investigators (DW, KR, CW, JB) together to standardize observations and interview methods. Remaining farm visits were made in pairs or by single evaluators. Surveillance results were compiled and analyzed (Microsoft Excel).

Results: Permissions were signed by 151/209 (72%) of producers. Milks (n = 1822) were collected from all tanks. 67 herds (44%) were either JD+ or BVD+: JD 58 (38%), BVD 14 (9%), 5 both. Proportion of positive herds' total samples positive ranged from: JD 5% - 100%; BVD 6% - 100%.

The same region was surveyed previously for JD. Of 67 farms JD+ 4 yr earlier, 25 did not participate or dispersed. 42 were retested: 28 (67%) remained JD+ and 14 (33%) tested negative. Of 103 farms JD-negative earlier, 65 were re-tested and 13 (20%) became newly +. Of farms JD tested for the first time, 17/44 (39%) tested +. Sensitivity (+ tank results/total number of tank samples tested from positive farms) for a single bulk milk sample test for the disease was: JD 284/528 = 54%; BVD 41/117 = 35%.

Visits were made to 22 farms, 21 JD+, one BVD+, one both. Means: 778 milking cows (52 - 6523), 305d milk 9240 kg (6773 - 11,509), SCC mean previous 6 mo 175,000/ml (94,000 - 300,000). Holsteins (95%) and Jerseys (5%) were main breeds. All parlor milking, 6 - 160 milking units. Freestalls for milking cows 91%, dry lots for dry cows 55%. JD+ farms had seen: cows becoming thin but eating 81%; cows diarrhea progress to death 52%. Both BVD+ farms had seen abortions. All 22 farms vaccinated vs. BVD.

When replacements last purchased (41% ≤ 1 yr ago): no testing or segregation 64%, vaccinate new animals 27%, segregate 14%, testing 11% (none for BVD or JD). Calves fed only individual colostrum and pasteurized milk 27%. No producers would segregate JD+ cows or have a separate calving area for JD+ cows or BVD+ cows.

Conclusions: Herd-level prevalence of JD and BVD were similar to previous reports. Most herds JD-positive 4 yr earlier remained so. Herds tested for the first time had the same prevalence of JD as herds tested for the first time 4 yr earlier. Positive herds' size, milk production and quality were above regional average. Most farms had seen disease signs.

Biosecurity was lacking. Most farms did not segregate or screen new additions for disease. Other recommended control practices were also poorly adopted. However, farms that participated in the earlier surveillance program and were JD-negative were less likely to become newly test-positive for JD.

Comments: If you do not think this fits in Epidemiology, please consider Herd Health Management: Dairy or Paratuberculosis as alternatives.

P03-003-071

Endemic infection with *Coxiella burnetii* in dairy cow herds follows a defined cycle

Benjamin Motsch¹ Camilla Alves¹ Britta Janowitz¹ Michaela Alex¹ Norbert Meier¹ Jens Boettcher¹

¹Bavarian Animal Health Service, 85586 Poing, Germany

Objectives: Q fever is caused by the zoonotic pathogen *Coxiella burnetii* (Cb). Serological diagnosis in human medicine relies on two antigens: Phase I (PhI) and Phase II (PhII). PhII-antibodies are detected early after infection, the development of high-level PhI-titers is indicative of a chronic course of infection. Individual milk samples from dairy cow herds were analyzed for phase-specific antibodies and age-related antibody profiles were assessed to get insights into the epidemiological dynamics of infection.

Materials and Methods: 2880 individual milk samples from 45 dairy cow herds (cows per herd: 64+/-23) were collected. PhI- and PhII-specific antibody titers were assessed and, provided the farmer agreed, the samples tested for Cb by quantitative PCR. In one chronically infected herd all animals (cows, heifers and calves) were additionally tested in a Cb-specific interferon-γ-recall assay (IFN-γ-RA). Finally, the phase-specific serological data from the previous year were available for another chronically infected herd and were compared with the current profile.

The age of each animal was recorded as year and month of birth (YYMM). For each herd a titer-over-age-profile was generated, by sorting the animals by age and depicting the associated titers as well as the moving average of titers for 5 animals.

Results: Three distinct titer profiles were observed at herd level, which we defined as (1) silent, (2) acute and (3) chronic profile. Prototypes are described as follows:

- (1) The silent profile was characterized by the absence of antibodies in cows younger than 3 years. A peak of PhI- and PhII-titers was frequently observed among a distinct age-group of older cows, probably the result of an infection in the past. Remarkably, older cows beyond this peak showed again a lower level of titers and a dominance of PhI/PhII⁺-pattern. Absence of antibodies in the whole herd is an exceptional case, which was rarely observed.
- (2) The acute profile was associated with a dominance of PhI/PhII⁺-pattern in 1st-lactation cows. PhI-titers are rarely observed, if detected they were restricted to defined age-groups.
- (3) The chronic profile was distinguished from the acute one by an abundance of PhI⁺-cows in almost all age-groups (>3 years).

In order to illuminate the aspect of cellular immunity, we analyzed blood samples from all animals for antibodies and IFN-γ. Heifers and calves (>6 months) were antibody-negative but showed a strong IFN-γ-reactivity. Introduction of such immune heifers most likely limits ongoing endemic infection.

The transition from acute to chronic was demonstrated in another farm, in which an acute profile had been observed in spring 2014. Eighteen months later the acute profile changed to a chronic one.

PhI-titers ≥ 100 along with qPCR-positive results (both in milk) are indicating a chronic shedding of Cb in milk. Such cows are detected even in herds with silent profiles.

Conclusions: Our data promote the idea of a defined Q fever cycle in dairy cow herds. The shift from the chronic into the silent stage relies on immunity of the young stock probably acquired in early calf hood. After some time in the silent stage susceptible calves and heifers are born and raised. A growing number of such susceptible cows increase the risk of an acute infection. Cows shedding Cb chronically in milk might be the source for reactivation of acute infection. Primary infection of susceptible cows results in PhII-titers; PhI-titers are generated later and some of these animals are going to establish a chronic shedding of Cb in milk.

Comments: This study was financially supported by the Free State of Bavaria and the Bavarian Joint Founding Scheme for the Control and Eradication of contagious Livestock Diseases.

First evidence of Schmallenberg virus introduction in Portugal, 2014

Fernando Esteves^{1*} João Mesquita¹ Rita Cruz¹ Helena Vala¹ Carla Santos¹ Joana Silva² Ana Coelho³ Wim Poel⁴ Maria Nascimento²

¹Escola Superior Agrária de Viseu, Viseu, ²Faculdade Farmacia Universidade do Porto, Porto, ³Universidade de Trás os Montes e Alto Douro, Vila Real, Portugal, ⁴Wageningen University, Wageningen, Netherlands

Objectives: Since the emergence of Schmallenberg virus (SBV) in 2011 this virus has spread over Europe, inclusively reaching Spain in March 2012. Despite the close proximity to the Portuguese border, until date there are no reports of SBV infection in Portugal. Hence, a serosurvey was set up to estimate the presence of IgG antibodies against SBV (IgG anti-SBV) in sheep of Portugal that could allow to infer about the circulation of this virus in the Portuguese territory

Materials and Methods: The sample size to estimate the occurrence of IgG anti-SBV in sheep of Portugal was calculated assuming SBV seroprevalence of 50% (yielding the highest possible sample size), confidence in the estimate of 95%, maximum allowable error in the prevalence of 3%, and population size of 1,852,940 sheep (official animal census data). A stratified random sampling design was set up with the 5 regions of Continental Portugal as a stratification level, according to the Nomenclature of Units for Territorial Statistics level II (North, Centre, Lisboa and Vale do Tejo, Alentejo and Algarve). Blood was collected from November to December 2014 from female sheep with 6 months to 10 years of age (N = 1,068) randomly selected upon the moment of the official brucellosis control. Sera were immediately separated and tested for the presence of IgG anti-SBV using an enzyme linked immunosorbent assay (ID Screen® Schmallenberg virus indirect, IDvet Innovative Diagnostics) according to the manufacturers' instructions.

Results: Of the 1,068 sheep serum samples tested for IgG anti-SBV, 137 were found positive, giving an overall SBV seroprevalence of 12.8% (95% CI 11.0%–15.0%). However IgG anti-SBV prevalence showed to be different in the different regions of the country, being 8.1% (95% CI 4.8%–13.3%) in the North of Portugal (13/161), 14.2% (95% CI 10.3%–19.2%) in the Centre (N = 34/240), 31.6% (95% CI 15.4%–54%) in Lisboa and Vale do Tejo (N = 6/19), 12.7% (95% CI 10.3%–15.5%) in Alentejo (79/624) and 20.8% (95% CI 9.2%–40.5%) in Algarve (N = 5/24).

Conclusions: This is the first nation-wide serosurvey providing evidence for Schmallenberg virus introduction in Portugal - The SBV seroprevalence in sheep showed to be lower in the North of Portugal than in the remaining parts of the country. We hypothesize that this could indicate that SBV was first introduced into the central or southern part of Portugal, at approximately the same latitude where the first SBV case in Spain occurred in 2012. Previous studies on the spatial distribution of *Culicoides* spp. in Portugal have shown that these vectors are mainly conformed to the central/southern regions of the country.

Bovine papillomavirus and its heterogeneous distribution in different host species in Italy

Federica Savini^{1*} Sara Mancini¹ Laura Gallina¹ Giovanni Donati¹ Giovanni Casà¹ Angelo Peli¹ Alessandra Scagliarini¹

¹Alma Mater Studiorum-University of Bologna, Bologna, Italy

Objectives: Papillomaviruses (PVs) are a wide variety of epitheliotropic viruses responsible for benign lesions' development that can occasionally progress to cancer. Even though PVs are considered highly species and site specific, Delta-genus Bovine papillomaviruses (BPVs) are known to cause cross species infection giving rise to sarcoids in horse and cat. At the light of the hypothesis that cross-species transmission has played an important role in PVs evolution, we evaluated the distribution of BPVs in their natural host and in diversely related species in Italy to deepen knowledge about tropism and transmission.

Materials and Methods: Cutaneous proliferative lesions clinically resembling papillomas on different anatomical sites of beef and dairy cattle, as well as healthy skin and mucosa from red deer, roe deer, chamois and mouflon, were collected from vet practitioners in Italy. Sampling was conducted in northern, central and southern regions. After DNA extraction, analysis for the identification of different BPVs was conducted by PCR with degenerated primers able to amplify specific genera and types.

In order to amplify also genomic DNA of unknown PVs, RCA (Rolling Circle Amplification) isothermal amplification and enzyme restriction analyses were also performed. Amplified products were subsequently sequenced and characterised.

Results: Papillomatous lesions demonstrated to harbor the genome of at least one PV. Interestingly, the diffusion was not homogeneous, as different genera were variously distributed on the territory, and many samples presented coinfections between types and genera. In wild ruminants, despite sampling of healthy tissues, an irrelevant number of samples harbored host specific papillomaviruses, while we extensively detected BPVs' DNA. Surprisingly, not only Delta BPVs, already known to cause cross-species infections, but also other genera were amplified from skin and mucosa.

Conclusions: Findings of BPVs presence in cattle lesions demonstrate a disomogeneous distribution of different genera ad types on Italian territory. In addition our results point out that the ability to cross-infect other species that was previously assumed only for Delta PVs, is potentially conceivable between other BPV genera. In conclusion our data contribute to a better understanding of papillomavirus epidemiology considering the possibility of indirect transmission between wild and domestic specie, and give further information about the role of sub clinically infected animal species.

Using Network Metrics to Predict Disease Spread from animal movements of the Cattle Tracing Scheme

Andrew Duncan^{1,2}George Gunn²Jude Eze²Roger Humphry²

¹Inverness College UHI, ²SRUC Epi Unit, Inverness, United Kingdom

Objectives: Our work had two **Objectives:** Firstly, to investigate cattle movement network to identify individuals and structures where control will have greatest effect on maintenance and transmission of disease; Secondly, to use the Cattle Tracing Scheme (CTS) to investigate the relative contribution of local movements and movements across regional boundaries to the risk of spreading diseases.

Materials and Methods: We used the CTS data to construct monthly contact networks of animal movements to and from individual holdings. The holdings were described by their business type (e.g. Market or Agricultural Holding). A variety of metrics (including betweenness, degree and clustering coefficient) were calculated to help describe the networks and to predict the influence each type of holding would have on disease spread. A high value of betweenness (the number of times a holding lies on the shortest path between two other holdings) has been used by others to predict which holdings are important in disease spread.

To establish the relative contribution of local versus regional movements to disease spread we used the county boundaries to partition the networks into within (intra) county and between (inter) county.

Results: Our main findings were that the average values for betweenness for the holdings described as Calf Collection Centre, Market and Showground are much higher than the other holdings. We also found strong (and unsurprising) evidence of seasonality over all holdings. The seasonality doesn't hold for all business types (e.g. Calf Collection Centres) but does hold for some (e.g. Markets).

Partitioning the network into intra county movements and inter county movements provides further information. The pattern of movements is consistent between the two partitions and the betweenness values from networks based on inter county movements are much larger than those based on intra county movements.

Conclusions: If betweenness is an indication of disease spread (as literature strongly suggests) then stopping inter county movements will have a bigger effect than stopping intra country movements. Likewise Calf Collection Centres, Markets and Showgrounds will have a larger influence on disease spread than the other types of holding.

Risk Factors For Calf Mortality During The First 24 Hours Of Life On Dairy Farms In Hokkaido, Japan, 2005 To 2009

Mutsuyo Kadohira¹Mitsunori Kayano¹Mark A. Stevenson²

¹Animal Science, Obihiro University of Agriculture and Veterinary Medicine, Obihiro, Japan, ²Veterinary and Agricultural Sciences, The University of Melbourne, Melbourne, Australia

Objectives: This was a retrospective cohort study using data from the

insurance scheme provided by the Japanese Mutual Aid Association (NOSAI). The population of interest comprised all cattle born on NOSAI-client farms in the Japanese prefecture of Hokkaido, Japan for the period 1 January 2005 to 31 December 2009 (inclusive). Our aim was to identify risk factors for mortality in calves that were either stillbirth or born alive but died during the first 24 hours of life.

Materials and Methods: Data were retrieved in digital format from the Hokkaido NOSAI office for all calves born throughout the study period. Details for each calf included the national identifier of the farm on which it was born, its date of birth, the national animal identifier of the calf's dam, the parity of the dam at the time of delivery, the number of calves delivered by the dam, and calf breed. A mixed-effects logistic regression model was developed to identify explanatory variables associated with first 24 hour mortality risk, with calves clustered within dams and dams clustered within herds. The final data set comprised details of 1,281,737 births on a total of 5,172 dairy herds from 19 NOSAI branches located throughout the prefecture of Hokkaido.

Results: Over the five year study period there were 7.39 (95% CI 7.35 to 7.44) deaths for every 100 deliveries. Factors that were positively associated with an increase in first 24 hour mortality risk included being born in the colder months of the year (November to March), calves of Wagyu breed, having a multipara dam, multiple (as opposed to single) birth deliveries, and increases in herd size. After adjusting for the fixed effects included in our multilevel model 88% of the unexplained variation in first 24 hour mortality risk was at the individual calf level.

Conclusions: We propose that the data recording requirements of the NOSAI scheme are extended to include details of calving events (e.g. the presence or absence of dystocia) and details of the way in which calves are managed post delivery. This would allow more subtle risk factors for calf mortality to be identified which, in turn, will lead to refinement of recommendations of the way calves should be managed during the first 24 hours post delivery.

Associations between Clostridium botulinum and unspecific chronic health problems in dairy herds – a case control study

Martina Hoedemaker¹Theresa Scheu¹Anika Wichern²Frieder Gundling¹Phuong Do Duc¹Amir Abdulmawjood³Svenja Fohler³Günter Klein³Katharina C. Jensen⁴Amely Campe⁴Lothar Kreienbrock⁴Sabrina Discher⁵Eva Jordan⁵Heinrich Neubauer⁵Christian Seyboldt⁵

¹Clinic for Cattle, University of Veterinary Medicine Hannover, Hannover, ²Lely Deutschland GmbH, Waldstetten, ³Institute for Food Quality and Food Safety, ⁴Institute for Biometry, Epidemiology and Information Processing, University of Veterinary Medicine Hannover, Hannover, ⁵Friedrich-Loeffler-Institute, Jena, Germany

Objectives: Since a couple of years, chronic herd health problems in dairy cows accompanied by many unspecific clinical symptoms eventually leading to long infirmity or death have been observed in Germany. Botulinum neurotoxin (BoNT) was found in the gastrointestinal tract and other organs of diseased animals. Therefore, a toxicoinfection with Clostridium (C.) botulinum was postulated and the disease was named chronic or visceral botulism. In order to study possible associations between chronic disease problems in dairy herds and C. botulinum or its BoNT, a case control study was performed. C. botulinum or the BoNT were considered the main risk factor.

Materials and Methods: Case farms had a history of chronic disease problems in the past and for verification, had to fulfill 3 out of 5 inclusion criteria: decreased herd milk yield (> 15%), increased culling rate (> 35%), increased death rate (> 5%), increased incidence of downer cows (> 10%), overall increased disease rate. Control farms (n=47) did not fulfill any of those criteria. Case 1 farms (C1: n=45) did not vaccinate against Clostridia, whereas Case 2 farms (C2: n=47) vaccinated against Clostridia, but not against *C. botulinum*. On each farm, 5 chronically ill cows and 5 unsuspecting cows underwent clinical examination and sampling (feces, ruminal fluid) (total n=1389). In addition, silage and water samples (n=406 and n=139, respectively) were collected. Clostridia diagnostic included anaerobic culture of fecal, ruminal fluid, silage and water samples with species differentiation using 16S rRNA sequence analysis, identification of BoNT toxin genes using singleplex real time PCR (all samples) and conventional singleplex PCR (fecal samples only) and identification of BoNT in fecal samples using mouse bioassay. A farm was considered positive when at least one animal sample tested positive in at least one of the assays. A cow was considered positive when at least one sample (feces, ruminal fluid) tested positive in at least one of the assays. Statistical analysis included Chi-square test or logistic regression.

Results: Out of a total of 7.934 investigated and suitable Clostridia isolates, only one was identified as *C. botulinum* type B. This isolate came from a control animal of a C2 farm. None of the fecal samples tested positive for BoNT. With respect to BoNT gene, 23.7% of the farms (C1: 22.2%; C2: 27.7%; control: 21.3%) were considered positive. The odds ratio for the occurrence of *C. botulinum* on herd level was 1.09 (CI: 0.48-2.49; P=0.74). On cow level, 109 cows (7.9%) were positive (C1 sick 6.2% vs healthy 5.8%; C2 sick 11.1% vs healthy 9.4%; control sick 6.4% vs healthy 8.1%). The frequency of positive results did not differ between animal groups within farm category or between farm category within animal groups (P>0.05). Out of 406 silage samples, only 11 (2.7%) from 9 farms had BoNT gene detection (C1: 9.8%; C2: 4.3%; control: 6.4%; P>0.05).

Conclusions: The fact that no BoNT was detected and toxin genes on herd and cow level were present in control and case farms to the same extent, strongly suggests that there was no direct and clear association between the occurrence of *C. botulinum* and chronic unspecific diseases in dairy herds. Therefore, it is not likely that *C. botulinum* is the main exposition factor for the problems on the affected farms. In addition, silages which are often discussed as a source of *C. botulinum* apparently played an inferior role in this respect. In conclusion, the results of this study did not give evidence for the existence of chronic/visceral botulism.

Differential diagnosis of the bovine neurologic disease in Paraná State, Brazil: between 2009 and 2015

Gustavo Queiroz¹, Priscilla F. V. Pereira², Rodrigo Azambuja³, Karina K. M. C. Flaiban⁴, Giovana W. di Santis⁴, Ana Paula F. R. L. Bracarense², Selwyn A. Headley², Amauri Alfieri⁴, Júlio A. N. Lisboa⁵

¹UNOPAR, ²UEL, Londrina, ³Cescage, Curitiba, ⁴DMVP, ⁵DCV, UEL, Londrina, Brazil

Objectives: The objective of this research was to investigate the occurrence and the causes of neurologic diseases in cattle in the State of Paraná, Brazil, from February 2009 to November 2015, establishing a differential diagnosis for rabies.

Materials and Methods: This research was conducted in the Veterinary Hospital of Londrina State University (HV-UEL) and in the farms where the diseases occurred. All the information about the evolution of the diseases in the individual and in other sick animals from the herd were recorded, as well as all the risk factors involved, and other relevant management information. All the procedures such as physical examination, neurologic examination, material collecting, preservation and processing were followed by a standard protocol. The following samples were collected from live cattle: blood, with and without anticoagulant and cerebrospinal fluid.

The necropsies were complete and tissues samples of all organs, including the central nervous system were collected including ganglion of the trigeminal nerve, carotid network mirabile and pituitary, and if necessary, the spinal cord.

The brain was collected and processed for histopathological examination, for polymerase chain reaction for detection of BoHV-1 and BoHV-5 genomes. Likewise, in each case attended, brain samples were sent to Diagnostic Center Marcus Enrietti (CDME) for the diagnosis of rabies, and if the animals were over 24 months of age, samples of brainstem preserved in formaldehyde were sent for diagnosis of BSE.

Results: Two hundred and nine cases were observed, either isolated cases or outbreaks, belonging to 123 different herds located in 77 counties. Approximately 90% of cases occurred in beef cattle. Of all cases investigated, only 7% remained inconclusive. Inflammatory and toxic diseases were the most frequent and accounted for 44% and 32% of cases, respectively.

Inflammatory causes such as meningoencephalitis caused by BoHV-5 (36%) and rabies (32%) were the most diagnosed diseases. Other diseases included thrombotic meningoencephalitis by *Histophilus somnus* (n=8), cerebral babesiosis (n=4), Listeriosis (n=2), BoHV-1 encephalitis (n=2) and Malignant Catarrhal Fever (n=2). Rabies occurred more often in the form of outbreak and BoHV-5 encephalitis most commonly in the form of isolated cases. Rabies affected cattle from various ages, while BoHV-5 encephalitis affected young cattle, less than 20 months. The most common degenerative cause of neurology disease was polioencephalomalacia, with 9 cases.

Toxic diseases consisted of 68 cases, the most important causes being the poisonous plants *Senecio brasiliensis* (n=8), *Crotalaria* spp. (n=7), *Senna obtusifolia* (n=6), *Tabernaemontana catharinensis* (n=5), *Senna occidentalis* (n=4). The tremorgenic syndrome by *Cynodon nlemfuensis* and *Cynodon dactylon* occurred in 8 cases, and nitrate/nitrite poisoning, in 5 animals. Carbamate, organophosphate, urea and mycotoxins poisonings were observed only one case each. Six cases of botulism, two cases of tetanus and two cases of enterotoxemia completed this list.

Conclusions: The conclusion of this research is that viral encephalitis, like rabies and BoHV-5 are the most important causes of bovine mortality in Paraná State. Followed by a large list of plant poisoning. Bacterial diseases have little epidemiological importance, presented as isolated cases. Listeriosis is a great cause of mortality in the northern hemisphere, but in this study only two isolated cases were reported.

Bovine Respiratory Syncytial Virus Seroprevalence Study In Bovine And Non-Bovine Species Of Agricultural Importance In Argentina

Alejandra Ferella¹ Carlos Margineda² Ayelen Sammarruco¹ Alejandra Romera¹ Silvina Maidana¹ Maria Sol Perez Aguirreburualde¹ Maria Jose Dus Santos¹ Marina Mozgovoj¹

¹INSTITUTE OF VIROLOGY, INTA, HURLINGHAM. BUENOS AIRES,

²EAA Marcos Juarez, INTA, Marcos Juarez, Argentina

Objectives: Bovine respiratory syncytial virus (bRSV) is the main cause of respiratory disease in young calves. The virus has been reported in many countries either by viral isolation or serologic studies. In Argentina, little is known about bRSV infection in cattle and the role of non-bovine species in the epidemiology. With the aim of evaluating bRSV circulation in both dairy and beef cattle and in non-bovine species (camelids, buffaloes, sheep and goats), a seroprevalence study was performed.

Materials and Methods: Cattle herds from Buenos Aires, Córdoba and Santa Fe provinces, in Argentina, were chosen for this study. In the case of beef and dairy herd, animals were random selected stratified by two age classes (6-18 months old and above 18 months). The first group involved 250 animals from 25 herds and the second group comprised 125 animals from the same herds. Antibodies against bRSV were also evaluated in cattle from 12 feedlots. Serum samples were taken from 230 animals older than 6 months in order to avoid colostral antibodies interference. To study the role of non-bovine species in epidemiology, sera were obtained from 10 llamas from Jujuy; 173 buffaloes from Corrientes, 36 sheep from 3 farms located in Jujuy; 60 goats from 6 farms located in a peri-valley area in the north of Rio Negro and 91 goats from 3 farms in Salta, all provinces in different regions of Argentina. None of the animals had been vaccinated against bRSV before sampling.

Results: Serum antibodies against bRSV were detected by virus neutralization test. Results showed that all herds had at least one positive animal for bRSV. The individual apparent seroprevalences were: 74.6% (6-18 months) and 97.9% (>18 months) in dairy cattle, 78.2% (6-18 months) and 94.9% (>18 months) in beef cattle and 78.6% in feedlot cattle. Old animals had the highest odds of being bRSV seropositive. Regarding non-bovine species, antibodies against bRSV were found in goats, from Rio Negro and Salta with seroprevalences of 86.9% and 95.5%, respectively. All sheep evaluated showed antibodies against the virus. Concerning buffalo samples 43% were positive for bRSV while 60% of the llamas showed low antibody titers against the virus.

Conclusions: Results presented here show that the virus is widely distributed not only among cattle but also in non-bovine species which might be involved in the epidemiology and transmission of bRSV. The presence of antibodies in non-vaccinated animals demonstrate that bRSV is circulating in our country so that control measures should be taken into account in order to prevent respiratory disease caused by this virus.

Applying Haddon's matrix to bovine injury prevention: An example using white line disease

Locksley Messam¹ Luke O'Grady¹ Alison Hanlon¹ Joris Somers¹

¹School of Veterinary Medicine: Herd Health and Animal Husbandry, University College Dublin, Dublin, Ireland

Objectives: Haddon's matrix is a model used to conceptualize injury occurrence. This model defines injury as energy transfer, by the agent to the host, in quantities or rates exceeding the tolerance of the host's tissue. While this approach has been used in human injury research for over 30 years to identify risk factors and develop preventive interventions, we have not seen it applied to animal injury. Lameness, an etiologically complex condition, is a source of both economic losses and welfare concerns to the cattle industry. We introduce Haddon's matrix as an approach to viewing traumatic animal injury using bovine white line disease as an example.

Materials and Methods: First, we identified three temporally distinct and successive phases of the injury process, each corresponding to a row of the matrix: The pre-event phase (the period prior to the transfer of mechanical energy to the white line), the event phase (the period during which mechanical energy is being transferred to the white line) and the post-event phase (the period subsequent to the transfer of mechanical energy to the white line). Second, we defined four interacting factors that contribute to an injury event, corresponding to the columns of the matrix: The host that sustains the injury (e.g. the cow); the agent, the object that transfers the energy to the host (e.g. a foreign body such as a stone); the overall physical environment in which the injury occurs (e.g. the farm, including the design of housing, floor surfaces and roadways, presence of pasture and herd size); and the socio-cultural environment or context: herd management (e.g. lameness control strategies, methods of herding etc.), cultural practices (e.g. awareness and attitudes to lameness) and animal welfare regulations. Finally, we used each cell of the 3 x 4 matrix as a focus for brainstorming and, guided in part by current literature, identified factors which could potentially a) prevent, b) limit the quantity of and c) reduce the consequences of energy transfer by various agents to the white line.

Results: The matrix enabled examination of factors as they pertained to specific phases of the injury process and thus facilitated evaluation of the feasibility of different phase-specific injury countermeasures. Thus it helped to compartmentalize a seemingly complex problem into manageable segments. Specifically, we found most potentially successful countermeasures applicable to either the prevention of energy transfer (pre-event phase) or the limiting of its consequences (post-event phase). Few event phase countermeasures were identifiable and deemed potentially capable of sufficiently limiting the quantity of energy being transferred to adequately protect the white line from injury. Additionally, each host, agent and physical environment countermeasure could be conceived as temporally consequent to a particular socio-cultural environmental (management) countermeasure. Finally, each host countermeasure, for example improving horn quality, had an analogue at the management level.

Conclusions: Haddon's matrix facilitates clear thinking while preserving a multidimensional approach to preventing white line disease. Given the impossibility of protecting the white line tissue once energy above a certain threshold is released, efforts should be expended primarily to prevent the release of energy in those quantities, and secondarily to reduce its consequences. Management-related countermeasures, being earliest in the causal pathway, are likely to be most influential in preventing white line disease and should take priority as preventive strategies. This is consistent with recent recommendations made by other authors.

The use of geographical information system for the surveillance of Bluetongue in the district of ASL Sassari (Sardinia)

Francesco Sgarangella ¹ Daniela Marongiu ¹ Sergio Masala ¹ Giuseppe Bitti ¹ Vincenzo Floris ¹ Marcella Porcu ¹ Pietro Desini ¹

¹Department of Prevention, Animal Health Service of ASL Sassari, Sassari, Italy

Objectives: Surveillance and prophylactic measures both direct and indirect are the means against Bluetongue. Through the surveillance system, data is acquired to provide information to show the presence or absence of viral circulation and to assess the risk related to the movement of sensitive species. The purpose of this paper is to present our experience on the use of GIS technology to provide information on the limitation of viral shedding and consequent ability to undertaken an early assessment of risk to health in the district of the ASL of Sassari.

Materials and Methods: Data was examined during the surveillance period from 2012 to 2015. Farms were selected for inclusion by the investigators if they partook in provisions of the National Manual for the Bluetongue Surveillance (April 2007). Using the GIS ArcView 9.1, the district of ASL Sassari was divided into 14 cells, 20 km², representing the geographical unit of reference for the surveillance activities. Within these areas the selected farms and the number of animals (including sheep, cow and goat) were monitored monthly for the presence of antibodies against the virus BT on serum samples.

This allowed us to acquire a monthly incidence of seroconversion of 2% with reliability of 95%.

The animals used as sentinel came from areas which had not been vaccinated and where there was no viral circulation. Blood samples were collected from the farms by the investigators, and subsequently analysed using the ELISA method of serum neutralisation to test for the BT virus. In 2012, 72 blood samples were collected every month from 10 bovine farms, 581 blood samples from 31 sheep farms and 32 blood samples from 3 goat farms. In 2013, 65 blood samples were collected every month from 8 bovine farms, 514 blood samples from 32 sheep farms and 23 blood samples from four goat farms. In 2014, 56 blood samples were collected every month from seven bovine farms, 477 blood samples from 27 sheep farms, 46 blood samples from 2 goat farms. In 2015, 36 blood samples were collected every month from 4 bovine farms, 382 blood samples from 19 sheep farms and 365 blood samples 16 goat farms.

Results: The results show that in 2012 there were no positive cases for any serotype. However, the situation changed in the following years. In 2013 for serotype 1, 24.31% of sheep, 89.23% of the bovines and 39.13% of goats tested positive.

In 2014 a small percentage (0.83%) of sentinel sheep, 32.14% of sentinel bovines and 2.17% of sentinel goats tested positive to serotype 1. In 2015, 2.77% of sentinel bovines and 3.56% of sentinel goats tested positive for the same serotype. For each animal seropositive with Bluetongue a cartographic buffer region of 4km² was enforced around the farm of origin. Within these areas of restriction animals identified as being species susceptible to bluetongue were subject to blocks in animal movements to prevent a possible viral spread. The process of geo-referencing has also allowed us to extrapolate on Microsoft Excel spreadsheets containing all owners of these farms and the corresponding phone numbers to send, via the Gateway software, a text message alert to update the receivers on the epidemiological situation of breeding and measures of restriction in place.

Conclusions: Through the use of GIS it has been possible to improve the surveillance program of Bluetongue, to update and view in real time, the epidemiological situation on cartographic basis for circulating serotypes.

By blocking the movement of animals from farms identified as being a source of Bluetongue, the system has made a large contribution to the elimination in 2010 of bluetongue virus serotype 4 and in 2011 the elimination of bluetongue virus serotype 2 from the territory of the ASL of Sassari.

Determination Of The Analytic Sensitivity Of An Elisa Indirect Test In Pool Serum For The Detection Of Bovine Brucellosis

Joaquin Baruch ¹ Alicia Von Gehlen ¹ Alejandra Suanes ² Jose Piaggio ¹ Andres Gil ¹

¹Bioestadística, Universidad de la Republica, ²DILAVE, Ministerio de Ganadería, Agricultura y Pesca, Montevideo, Uruguay

Objectives: Bovine brucellosis (Brb) is a worldwide distributed disease with a public health importance and economic impact. In Uruguay the prevalence of the disease goes around 0.8% among farms, in this stage of advanced control, there are several diagnostic tests been implemented in surveillance such as, Rosa Bengala test (RB) implemented for individual animals and ELISA in milk pools. According to different authors the ELISA test has a high sensibility for this disease, therefore the possibility of making serum pools. The objective of this study was to determine the analytic sensitivity of an indirect ELISA test in serum pools.

Materials and Methods: 62 positive serum samples to the RB test and confirmed by Rivanol or Fluorescent Polarization test were used in this study. These samples were diluted with negative sera from animals that did not belong to farms with reactors for the disease, this sera were also negative to RB test. The dilutions were carried out in a 2 base up to 1/1024. The ELISA test was applied to original samples and the dilutions to determine the analytic sensibility of the pool samples. The results were analyzed by a Probit model in a STATA 13.0 software.

Results: The mean of the analytic sensibility for the dilutions are: 1/4 (98.2%), 1/8 (96.8%), 1/16 (94.4%) and 1/32 (90.9%), if the serum is diluted to greater proportions the analytic sensibility decrease. The use of an ELISA test in pool serum can be implemented as a strategy for the declaration of farms free of Brb, since the probability of detecting a positive pool is more likely to be low in the country disease situation. Considering the costs of both tests (RB and ELISA) the cost of the RB test goes around 1USD per sample, and the cost of the ELISA is 2USD, beside of this in the situation that the pools are made of 16 samples the national cost of the diagnostic campaign decrease in 8 times. In total in Uruguay with the sanitary obligations for the dairy cows, the beef farms that are under control or side to control farms and the sampling in slaughterhouse the number of animals analyzed per year goes around 2 million.

Conclusions: With a campaign that annually analyzes more than 2 million individual samples, in a country perspective of 0.8% prevalence among farms, the probability of obtaining a positive pool is low and the need to analyze a pool as an individual sample is unlikely. In this national campaign, the cost of the test been implemented are paid by

the farmer, with the implementation of pool samples this will result in lower production cost to agricultural producers and less number of staff needed in the laboratories.

Prevalence study on diseases observed on cattle for slaughter and on the causes of exclusion of the meat for human consumption

Rolando Piccioni¹; Monica Castagna²

¹ASL N. 4 TERAMO, MONTEPAGANO, ²freelancer, Pineto, Italy

Objectives: The purpose is to collect clinical and anatomo-pathological evidences in the slaughterhouse and to analyse the capacity of the inspection for reveal the diseases and the other conditions recognized as a ground for excluding beef from human consumption. This study investigates the role of the slaughterhouse as an epidemiological observatory.

Materials and Methods: The study has been conducted for 45 months on cattle slaughtered in the establishment IT034MCE current in the Province of Teramo (Italy), from 01.04.2011 to 31.12.2014. The observed cattle population is composed of 14512 bovines. The animals only in a small percentage come from the territory next to the slaughterhouse (25-30%), the rest is of national or Europe Union origin. The data of the results of inspections and decisions concerning live animals and meat have been registered in the database provided for by EC Reg. 854/2004. There have been considered the clinically cases of disease confirmed during ante and post mortem inspection, and the causes of exclusion of meat from human consumption. In addition to the absolute number of cases, it has been calculated the prevalence in comparison with the animals inspected. There have been considered "cases" all the ones confirmed by the official veterinarian. The cases have been classified according to the categories of diseases and the causes of exclusion of meat from human consumption provided for by the art. 5, Annex I, Section I, Chapters I, III and V of EC Reg. 854/2004.

Results: From 14512 cattle slaughtered 752/5,18% has been suffering from disease. Among the sick ones 19/2,53% has had generalized illness; 13/1,73% has been emaciated; 143/19,01% has been suffering from hydatid disease (zoonosis); 161/21,41% from other non-zoonotic parasitosis; 307/40,83% has been suffering from aspecific localized inflammations and 103/13,70% from degenerative diseases. In 6/0,80% cases other factors have required that the meat had been declared unfit for human consumption. There have been 753 animals of which meat has been excluded. The exclusion has been total in 37/4,92%. 1/0,13% bovine has died before slaughter, 19/2,52%, has been suffering from general disease, 13/1,74% has been emaciated, in 1/0,13% the bleeding has been insufficient and in 3/0,40% cases the meat has presented organoleptic anomalies. It has been partial in 716/95,08% cases: in 404/53,65% for physiopathological alteration of single organs or systems; 307/40,77% for parasitosis of single organs. In 5/0,66% cases the exclusion of the meat has been due to technological errors (foulness). Among the noticed diseases prevail the located ones (parasitic or related to inflammatory aspecific processes) for which it is sufficient the exclusion from the consumption of the only affected tissues or organs. The control in the slaughterhouses has been efficacious as regards the prevention of zoonosis as hydatid disease and the identification of animals suffering from systemic diseases (septicemia, pyaemia, viremia, toxemia) that can make dangerous the meat of the whole carcass for the human consumption.

Conclusions: The slaughterhouse is still an epidemiological observation post essential it reflects the epidemiological situation of populations. The routine inspection along with informations on the food chain effectively pursues the objectives of consumers protection. However only in the case of animals suspicious of disease that may negatively affect human or animal health will follow a thorough examination to obtain an etiologic diagnosis. In the other cases the sensitivity of the inspection method and therefore the role of epidemiological observatory as regards non-zoonotic diseases or for which there aren't provided for measures of health are reduced.

Liver fluke (*Fasciola hepatica*) infection in cattle in Northern Ireland: a large-scale epidemiological investigation utilising meat inspection data

Andrew Byrne¹; Stewart McBride¹; Angela Lahuerta-Marin¹; Maria Guelbenzu¹; Jim McNair¹; Robin Skuce¹; Stanley McDowell¹

¹Veterinary Science Division, Agri-food and Biosciences Institute, Belfast, United Kingdom

Objectives: Liver fluke (*Fasciola hepatica*) is a widespread and common parasite of ruminants in Northern Ireland. Liver fluke infection status (for non-clinical cases) at the animal level is captured during meat inspection of all animals processed for human consumption within Northern Ireland. These large datasets have not been analysed to assess their utility in uncovering trends in fluke infection at animal and herd levels in Northern Ireland.

Materials and Methods: We utilised a dataset of 1.2 million animal records from 18000 herds across three years (2011-2013) to assess animal and herd level apparent prevalence and risk factors associated with fluke infection. Data from routine meat inspection surveillance were gathered from the Animal and Public Health Information System (APHIS) for Northern Ireland. Appropriate data cleaning was undertaken before exploratory descriptive analysis. Animal level prevalence was measured as the proportion of animals exhibiting evidence of fluke infection at slaughter; herd-level infection prevalence was measured by categorising herds into infected or not (binary), if at least one animal exhibited at least one infected animal per unit time. "Within herd" infection prevalence was measured using the proportion of animals within a herd that showed evidence of fluke infection (ranging from 0-1), with the inclusion criteria of a minimum of 13 animals sampled per herd per year. "Within herd" infection prevalence at the herd level was investigated using logistic regression, Generalised Linear models (GLM) and Fractional Response Regression (FRR), with spatial patterns presented using Geographic Information Systems (GIS).

Results: At the animal level, the proportion of animals slaughtered that exhibited evidence of infection varied between 20-25% amongst years. Across herds, the proportion of herds with at least one infected animal, varied between 60-65%. There was however a significant sampling effect at the herd-level; all herds where at least 105 animals slaughtered over the study period exhibited evidence of fluke exposure (100%).

There was significant variation in terms of within-herd infection prevalence risk as elucidated by GLMs and FRRs. Risk factors included herd type, long-term climate variation, geographic location (region) and the abattoir where animals were processed.

Conclusions: Liver fluke prevalence was high at the herd level. However, there was a lower prevalence at the animal level, which may indicate variation in exposure within herds. Within herd prevalence varied significantly in time and space, and by abattoir, herd-type and some climate variables. These data are a useful source of information on a widespread and endemic disease, despite known limitations in terms of performance (low test sensitivity). As well as informing on the distribution and severity of liver fluke infection within herds in Northern Ireland, these analyses will be used to investigate the effect of co-infection with bovine tuberculosis.

Prevalence of *Coxiella burnetii* (Q fever) in Polish cattle population

Monika Szymańska-Czerwińska¹, Krzysztof Niemczuk¹, Agnieszka Jodelko¹, Dariusz Bednarek¹

¹Cattle and Sheep Diseases, NVRI, Pulawy, Poland

Objectives: Q fever is an infectious disease of animals and humans. The biggest worldwide outbreak of Q fever took place between 2007 and 2010 in the Netherlands and initially it was considered as the cause of increasing prevalence in other European countries. Recent phylogenetic analyses show that strains isolated from cows from other European cattle belong to different cluster than the Dutch one. Increasing number of Q fever cases is probably due to the lack of surveillance and eradication programs in most of Member States. There for the aim of this study was to assess the prevalence of *Coxiella burnetii* in cattle herds in different regions of Poland.

Materials and Methods: The study was performed at the turn of 2014-2015 on 1,150 serum samples collected from cattle in different provinces and counties. The samples were taken from 443 cattle herds. The sera were tested by complement fixation test (CFT). CFT assay was done using reagents supplied by Siemens (Germany) according with manufacturer's instruction. The mixed antigen of *C. burnetii* (phase I and phase II) was used. Moreover, bulk tank milk (BTM) were taken from 25 seropositive cattle herds and tested by qPCR. Additionally, 30 commercial milk and dairy product were tested by PCR. DNA isolation from milk and dairy products will be performed with use of commercially available kit QIAamp DNA Mini Kit, according to the manufacturer's instructions. For the qPCR test, a commercial kit targeting the repetitive transposon-like region (IS1111) of *C. burnetii* (AdiavetÖCOX REALTIME) was used. Samples with cycle threshold (Ct) values below 37 were positives.

Results: The data indicated that *C. burnetii* serologically positive cattle was detected in all provinces under this study. The percentage of seropositive herds range from 15.79% in Warmińsko-Mazurskie province to 84.62% in the Mazowieckie province with an average of 40.41%. Surprisingly, the seroprevalence below the national average was in Podkarpackie (29.91%) which is included in the endemic area of Q fever. Presence of repetitive transposon-like region (IS1111) was confirmed in 8/25 (32%) BTM. The Ct value for positives BTM was ranging from 28.8 to 36.8. Moreover, in ten commercial milk and dairy product positives results of qPCR were noted.

Conclusions: The data presented in this study shows that *C. burnetii* is widespread in Poland, and the surveillance has to be continued. Especially as Q fever is zoonotic disease and there is a high risk transmission to humans. Particularly that transmission to humans by alimentary route cannot be ruled out.

Evaluation Of The Implementation Of The Program Of Control Of Bovine Brucellosis In The Manabi Province, Ecuador

Marina Dalila Zambrano Aguayo¹, Miguel Perez Ruano²

¹Facultad de Ciencias Veterinarias, Universidad Técnica de Manabí, Portoviejo, Ecuador, ²Preventive Medicine, Faculty of Veterinary Medicine, Agrarian University of Havana, Mayabeque, Cuba

Objectives: In Ecuador there is a national program to combat brucellosis is voluntary compliance and therefore the application level is not known, which is why we propose aim of this study to know the level of compliance with the measures ordered by the in the Manabi province.

Materials and Methods: A cross-sectional epidemiological study was conducted in the period November 2014 to March 2015 in cattle herds of Chone, El Carmen, Sucre, Jama, Bolivar, Tosagua and Junin cantons of Manabi province. For determining compliance with the aspects covered by the national program for control of bovine brucellosis (AGROCALIDAD, 2009) an epidemiological survey in 20 affected herds and 20 unaffected herds randomly selected in the territory was applied.

The factors taken into account in the assessment of compliance were: proper use of vaccination, have veterinary assistance, investigation of herd annually, development of surveillance activities, removal or compulsory segregation of positive reactors, sanitary control of entry and exit of animals, biosecurity and herd development of health education activities.

The data were recorded in a spreadsheet of Microsoft Excel. The percentage of compliance with each of the aspects referred to in brucellosis control program was calculated and the level of compliance among affected and unaffected herds was compared using the chi-square test and statistical package Vassarstats.net.

Results: A low compliance of the measures proposed in the control program was determined, only the veterinary assistance measure obtained more than 50% of compliance, in the rest of the aspects it was demonstrated a very low compliance level (table 1).

Table 1. Compliance level of the different aspects covered in the National Programme for Control of Bovine Brucellosis in the studied territory of Ecuador.

Measures	Compliance (%)
Vaccination	15.00
Veterinary assistance	67.50
Periodical test of the animals	0.00
Serological Test at the animals entrance into the herd	27.50
Epidemiological Surveillance	2.50
Culling of infected animals	5.00
Biosecurity	5.00
Health Education	7.50

It was found that herds free of the disease showed a better performance in their compliance with the measures, veterinary care and serological testing of animals before they enter the herd. It was also found that 100% of vaccinated herds were not infected, demonstrating the importance of this measure.

Conclusions: There is a low level of compliance in control measures of bovine brucellosis in the areas studied in the Manabi province of Ecuador. The importance of vaccination on disease control was demonstrated in this article.

Seroprevalence of *Mycoplasma bovis* in affected cattle population in Poland

Dariusz Bednarek¹ Ewelina Szacawa¹ Monika Szymanska-Czerwinska¹ Katarzyna Dudek¹ Krzysztof Niemczuk¹

¹Department of Cattle and Sheep Diseases, National Veterinary Research Institute, Pulawy, Poland

Objectives: *Mycoplasma* spp. belongs to Mollicutes class. Among the bacteria they have the smallest genome size. *M. bovis* is thought to be the main pathogen of calf pneumonia. *M. bovis*-associated pneumonia may occur in cattle in different age. *M. bovis* also can cause pathological changes in the mammary gland, joints, conjunctival sac, ears, infertility and abortions. It causes significant economic losses in cattle industry. The aim of this study was to assess the seroprevalence of *Mycoplasma bovis* in cattle herds that indicate the symptoms of mycoplasma infection derived from different regions of Poland.

Materials and Methods: The study was performed during 2014 – 2015. In total 713 serum samples from 73 cattle herds were examined. There were examined from 6 to 75 animals from each herd (on average 10 animals from a herd) affected with pneumonia, arthritis or mastitis. The animals derived from different regions of Poland. The presence of specific anti-*M. bovis* antibodies in the tested serum samples was determined using the commercial indirect ELISA. The sera were tested by ELISA (BioX Diagnostics) according to manufacturer's instruction.

Results: The presence of anti-*M. bovis* antibodies was detected in 30.14% (22/73) herds. The percent of the positive herds ranged from 0 to 45.5% regarding to the region. The highest result was recorded in Northwestern Poland – 45.5% (5 herds from 11), lower results were recorded respectively in: Central Poland – 42.9% (6/14), Southwestern Poland – 40% (2/5), Eastern Poland – 36.4% (8/22) and North Poland – 7.14% (1/14). In South Poland the presence of anti-*M. bovis* antibodies was not detected in any of the 7 herds.

Conclusions: The data presented in this study shows that anti-*M. bovis* antibodies are present in Polish cattle population at a significant level, which can vary regarding to the region. To define the presence of active infection of *M. bovis* in the herd, the examinations should be expanded to the bacteria detection with the use of culture and molecular methods.

Comments: The study was supported by the Polish National Science Centre grant No. 2013/09/N/NZ7/02158 entitled: "The prevalence and molecular characteristic of *Mycoplasma bovis* infections in cattle in Poland." (2014-2016).

The upper respiratory tract microbiome and its potential role in bovine respiratory disease and otitis media

Svetlana Lima^{1*}

¹Cornell University, Ithaca, United States

Objectives: The objective of this study was to use high-throughput sequencing of the 16S rRNA gene to characterize the microbiome of the

URT of Holstein dairy calves from day 3 to day 35 of life and to describe its associated bacterial diversity. In addition, we aimed to compare the microbial community of the URT of healthy and unhealthy subjects at each time point of our data collection.

Materials and Methods: A cohort study was conducted including 174 calves categorized prospectively as healthy, pneumonia only, otitis only, or pneumonia-otitis combined. Deep pharyngeal swab samples were collected on days 3, 14, 28, and 35 of life. Isolation of DNA from swabs of the URT was performed. The 16S rRNA gene was amplified by PCR from individual metagenomic DNA samples from the URT using barcoded primers. For amplification of the V4 hypervariable region of the bacterial/archaeal 16S rRNA gene, primers 515F and 806R were used according to previously described methods and optimized for the Illumina MiSeq platform. Aliquots of URT amplicon samples were standardized to the same concentration and pooled into 5 different runs according to individual barcode primers for the 16S rRNA gene. Final equimolar libraries were sequenced using the MiSeq reagent kit v2 (300 cycles) on the MiSeq platform. The generated 16S rRNA gene sequences were processed through the open source software pipeline Quantitative Insights Into Microbial Ecology (QIIME) version 1.7.0-dev. Sequences were binned into Operational Taxonomic Units (OTUs) based on 97% identity using UCLUST against the Greengenes reference database. We generated a species-level OTU table using the MiSeq Reporter Metagenomics Workflow. In order to determine the bacterial load of the URT samples and its difference between each health status examined we performed a qPCR assay.

Results: Our results showed that the URT microbiome is dominated by the phyla Proteobacteria, Tenericutes, Firmicutes, Bacteroidetes, Actinobacteria, Fusobacteria, Spirochaetes, and Cyanobacteria. Thirty genera were shared across the four age groups and health statuses. At days 14 and 28, the relative abundance of the genus *Mannheimia* increased in calves with pneumonia and pneumonia-otitis combined compared to healthy animals. At day 28 alone, the relative abundance of *Mycoplasma* increased in calves with pneumonia and pneumonia-otitis combined compared to healthy calves. Interestingly, *Moraxella*, a bacterium not previously associated with pneumonia and otitis in calves, showed increased relative abundance at day 14 in animals diagnosed with pneumonia, otitis and pneumonia-otitis combined. *Pasteurella*, a bacterium previously reported to be associated with bovine respiratory disease and otitis, did not exhibit a significant difference in abundance between healthy calves and calves diagnosed with pneumonia, otitis or pneumonia-otitis combined.

Conclusions: This study demonstrated that the URT of calves across the four ages examined harbored a similar microbial structure regardless of health status (suggesting that a commensal microbiota is dominant), an increase in the likelihood of developing respiratory diseases leads to variation in some specific microbe abundances. Both age and pathogenic agents appear to be important in determining the health of the calf respiratory tract. For the first time, *Moraxella* was associated with pneumonia and otitis in pre-weaning dairy calves, which call for further investigation into its potential role on the health of the respiratory tract and middle ear.

The prevalence and risk factors for antibodies to *Coxiella burnetii* (Q fever) in bulk tank milk samples from Irish dairy cattle herds

Eoin Ryan^{1*} Karina Wrigley² Ann Hallinan² Guy McGrath³ Tracy Clegg³

¹Central Veterinary Research Laboratory, Department of Agriculture Food and the Marine, Backweston Campus, Celbridge, ²Cork Blood Testing Laboratory, Department of Agriculture, Food and the Marine, Cork, ³Centre for Veterinary Epidemiology and Risk Analysis, School of Veterinary Medicine, University College Dublin, Dublin, Ireland

Objectives: *Coxiella burnetii* is the causative agent of Q fever, a zoonotic disease of increasing public health importance which also causes abortion and fertility problems in cattle. The objective of this work was to estimate the prevalence of antibodies to *C. burnetii* in samples of bulk tank milk collected from Irish dairy farms, to determine whether positive herds clustered spatially, and to investigate the strength of association between certain putative risk factors and positive status.

Materials and Methods: Bulk tank milk (BTM) samples from Irish dairy farms were collected by dairy processors during the summer of 2015 in the context of a collaborative initiative between the dairy industry and the Irish Veterinary Laboratory Service of the Department of Agriculture, Food and the Marine (DAFM). 1,489 BTM samples were randomly selected from the total of 14,464. The survey was designed based on prior estimates of true prevalence of 0.35 (based on work conducted in 2010), test sensitivity of 0.9, test specificity of 0.9, population size (number of dairy herds participating) of 18,000, confidence of 0.95 and precision of 0.03, using epitools software (www.epitools.eu). BTM samples were tested using a commercial ELISA kit according to the manufacturers' instructions. Herd level data extracted from the DAFM animal identification and movement (AIM) database is used to evaluate herd-level risk factors for positivity, with spatial analysis conducted using ArcGIS.

Results: 21.6% of BTM samples tested positive; true prevalence was estimated as 19.5% of dairy herds based on Se/Sp estimates of 0.9 and 0.95 respectively, with a 95% confidence interval (CI) of 17.5 to 21.5%. This contrasts with the estimated dairy herd prevalence of 38.7% (95% CI 33.1 to 44.3%) reported in a survey which used bulk tank milk samples collected in 2009 (Ryan et al, 2010). An analysis of herd-level risk factors is presented, and the spatial distribution and analysis is displayed in map format.

Conclusions: This survey provides an updated estimate of *Coxiella burnetii* exposure in Irish dairy herds. As the Irish dairy sector is due to expand significantly under the national agricultural strategy (FoodWise 2025), it is essential to monitor any changes in diseases related to this, particularly zoonotic diseases. This study helps to inform policy makers in responding proportionately to concerns in relation to this zoonotic infection of increasing public health importance.

Molecular epidemiology of bovine viral diarrhoea virus (BVDV) in Spain between 2007 and 2015, spatial and temporal distribution.

Fernando Esperón¹Laura Elvira²Ana de la Torre¹Verónica Delicado¹Marcelino Álvarez³

¹Animal Health Research Center (INIA-CISA), ²MSD Animal Health, Madrid, ³Animal Health Department, University of Leon, Leon, Spain

Objectives: BVDV causes major economic losses in ruminants. Genotypes, BVDV-1 and BVDV-2 have been described. In Europe, BVDV-1 is most frequently isolated. In Spain, BVDV-1b is the most

prevalent subtype, but recently BVDV-2 has been reported for the first time. Studies on the molecular epidemiology of BVDV will provide valuable information about the diversity of the viral strains present in Spain. The objectives of the present study are to: 1) identify the genotypes of BVDV in Spain from 2007-2015; 2) study the spatial and temporal clustering for each genotype, and 3) investigate the trends of diversity of the genotypes along the time.

Materials and Methods: Cattle sera from 164 viremic animals, previously diagnosed by antigen ELISA, were randomly selected from a sera bank collected from 2007 to 2015. For genotyping, a one-step RT-PCR which amplifies a 288 bp of the 5' untranslated region (5'-UTR) previously described was carried out. Products of RT-PCR were sequenced.

The sequences obtained were aligned, and those 100% identical were grouped as nucleotide sequence types (ntST). In order to classify the sequences in the study into different genotypes and subtypes, a maximum likelihood tree with a bootstrapping of 1000 replicates was made with ntST and the reference sequences. In addition, to investigate the spatial and temporal clustering of the sequences, two neighbor-joining networks were constructed, one representing the regions and the other one the years of sampling. For the network analysis all sequences previously described in the Genbank from Spain were also included, all of them being collected from 1999 to 2002.

Results: Main results revealed a high genetic diversity, identifying 88 ntST out of 164 total sequences obtained. All of them belonged to genotype 1. Among subtypes, 1b was the most frequent, representing the 79.9% of total sequences obtained (131/164) and the 77.3% of all ntST (68/88). Other subtypes found were 1f (7.9% total sequences and 11.4% ntST), 1e (6.1% total sequences and 2.3% ntST), 1d (4.3% total sequences and 6.8% ntST), and 1h (1.8% total sequences and 2.3% ntST).

No regional or temporal clustering was observed for each subtype, with the exception of subtype 1h that was only found in one region (Castilla y León) and in one year (2014). In fact, some frequent ntSTs were detected in up to six different regions out of 10 included in the study. Regarding the evolution of the diversity of subtypes, 1b and 1e were found from 1999 to 2015 and from 1999 to 2013, respectively. Eight ntST were present since 1999-2002 to 2007-2015, revealing a certain stability of predominant sequences. Subtypes 1d, 1f and 1h were identified for the first time in 2007, 2008 and 2000, respectively.

Conclusions: The results obtained in the network demonstrate the predominance of subtype 1b in Spain since 1999, which seems to be enzootic. The recent introduction of subtypes 1d and 1f highlights the importance of periodic genotyping of BVD in order to obtain relevant epidemiological information about the evolution of the different subtypes along the time.

Epidemiological investigation of prevalence, risk factors and prevailing sequence types of *Brucella* in ruminants of India

Padmashree Bengaluru Shankaranarayana^{1,2}Rajeswari Shome¹Krithiga Natesan¹Bibek Ranjan Shome¹Habibur Rahman¹ and DBT Network Project on Brucellosis

¹Bacteriology, ICAR- National Institute of Veterinary Epidemiology and Disease Informatics, ²Biochemistry, Jain University, Bengaluru, India

Objectives: Brucellosis is a serious zoonotic disease infecting multiple hosts of land and water. Its taxonomy, host preference and epidemiology are continuously emerging and confusing. In India, 5% decline in national milk production for every five years and loss of 2.63 million female calves per annum with the annual economic loss of US\$ 3.4 billion due to brucellosis have been estimated. The present study was an investigation of prevalence, risk factors and prevailing sequence types in ruminants of India. The study also highlights the comparative analysis of MLST sequences of regional field isolates with that of other Indian and global isolates.

Materials and Methods: Serum samples collected from ruminants of species-cattle, buffalo, sheep and goat were screened by rose bengal plate test (RBPT), indirect enzyme linked immunosorbent assay (iELISA) and bcs31 PCR. Statistical analysis was performed using SPSS software for investigation of risk factors at both animal and herd level. Vaginal discharge and aborted materials were used for isolation. Isolates were analyzed by biochemical and molecular tests (bcs31 genus PCR, AMOS and Bruce ladder PCRs for speciation). Confirmed isolates were sequence typed by multilocus sequence typing (MLST). To determine sequence divergence and phylogenetic relationship among the regional isolates and with other Indian and global isolates, neighbour joining tree was constructed using MEGA 6 software.

Results: A total of 2529 ruminants (Cattle-1233, Buffalo-212, Sheep-719 and Goats-365) were sampled. Among these, 9.43%, 9.32%, 8.06% and 7.12% were declared as seropositive in buffaloes, cattle, sheep and goats respectively. In PCR, 2.08 to 5.6% samples were showed positive amplification in different species of ruminants, thus confirming the active infection status in herds. Ten out of fifteen risk factors analyzed (breed, age, breeding method, history of abortion/ other clinical sign, purchase of new animal, routine diagnosis, veterinary assistance, herd size, hygienic status of farm, education of farm owner and brucellosis awareness) were found statistically significant. A total of thirty field isolates were confirmed by biochemical and molecular tests. MLST typing of field isolates along with reference strains revealed the five distinct sequence types and their spatial distribution in India. B. melitensis isolates of India were typed as ST 7 and ST 8. ST1 found as predominant sequence type among the field isolates of B. abortus from India and among available B. abortus genome sequences from different parts of the world during the period 2000-2015. Also the study underlines the genetic relatedness of the B. abortus S19 vaccine and B. abortus S99 antigenic strains.

Conclusions: The study revealed that organized farms of ruminants in India were significantly affected with brucellosis. Isolation and Brucella DNA in sera, confirmed the active infection status. Thus greater attention needs to be given for brucellosis awareness, pre-purchase testing and routine screening. This is the first attempt to document the sequence diversity of Brucella in India. The knowledge about prevailing sequence types, key routes of infection transmission and risk factors will be helpful to develop suitable control strategies and policies. Also decisive in discriminating between naturally occurring outbreaks and bio terroristic incidences.

Comments: Acknowledgement: Department of Biotechnology, Govt. of India, India.

Comparative Bacteriological And Molecular Detection Of Group B Streptococcus From Bulk Tank Milk Samples

Ana S. Jaramillo-Jaramillo¹ on behalf of CLEV Claudia G. Cobo-Angel^{1*} on behalf of CLEV Laura M. Lasso-Rojas¹ on behalf of CLEV Sandra B. Aguilar-Marin¹ on behalf of CLEV Juan C. Rodriguez-Lecompte² Alejandro Ceballos-Marquez¹ on behalf of CLEV

¹Universidad de Caldas, Manizales, Colombia, ²University of Prince Edward Island, Charlottetown, Canada

Objectives: The aim of this study was to evaluate and compare two diagnostic tests for the detection of Group B Streptococcus (GBS) in bulk tank milk (BTM) samples: The selective chromogenic medium for the screening of GBS (ChromeID[®]) and the molecular Polymerase Chain Reaction (PCR).

Materials and Methods: Ninety-five BTM samples were purposively selected out of a total of 462 GBS isolations. These isolates were previously positive to CAMP reaction in an initial screening. Samples were submitted to the milk quality laboratory of Universidad de Caldas for GBS detection by culture and PCR. All samples were cultured on a Chrome Id[®] media (Biomerieux, Marcy-l'Étoile, Francia), and aerobically incubated at 37 °C for 24-48 h. According to the manufacturer's instruction, presumptive positive colonies for GBS were those observed as red or pink. Chromosomal DNA was isolated from apparent positive and negative colonies using the UltraClean Microbial Isolation Kit[®] (MoBio Laboratories Inc. Carlsbad, United States). Molecular confirmation was done by PCR species-specific, following the methodology reported by Elias et al. (2012). Samples were classified as 0 for negative and 1 for positive to the either test. Considering PCR as the complementary confirmatory test, data were analyzed calculating the sensitivity (Se), specificity (Sp), positive (PPV) and negative (NPV) predictive values for the Chrome ID[®]. The McNemar's test was used to compare the proportion of positive isolations to Chrome ID[®] and PCR tests. Statistical analyses were done in Stata 14[®] (Stata Corp. College Station, TX, USA).

Results: The general prevalence of GBS among herds was 77.8%. However, 68 isolates out of the 95 were confirmed as SGB by PCR (71.6%). Sixty-three isolates were classified as truly positives (66.3%), 3 (3.2%) were truly negatives, 24 (25.3%) were false positives, and five (5.3%) isolates were false negatives. The negative isolates were not molecularly classified into another group of bacteria because it was beyond of the scope of this study. The Se of the chromogenic media was 92.7% (95% IC: 83.7% - 97.6%), while the Sp was 11.1% (95% IC: 2.4% - 29.2%). The PPV was 72.4% (95% IC: 61.8% - 81.5%), and the NPV was 37.5% (95% IC: 8.5% - 75.5%). The McNemar's statistic indicated significant differences (P<0.01) in the proportion of positive isolations between tests; therefore, the Cohen's kappa (k) agreement statistic was not calculated (Dohoo et al., 2009).

Conclusions: Our results showed a significant difference in the proportion of positive samples between both chromogenic media and PCR tests. Despite of the high Se of the chromogenic media (Chrome ID[®]), the Sp of the test was low. These results indicate that the chromogenic media (Chrome ID[®]) can be used as a screening tool for detecting GBS; however, it is important to use a confirmatory test to avoid the false-positive results.

Photosensitivity associated with Pithomycotoxicosis in Azores – PortugalClara Dias^{1,1*}Helder Cortes²Carlos Pinto³

¹University of Évora, ²Victor Caeiro Laboratory of Parasitology, Instituto de Ciências Agrárias e Ambientais Mediterrânicas (ICAAM), University of Évora, Núcleo da Mitra, P.O. Box 94, 7006-554, Évora, ³Serviço de Desenvolvimento Agrário de São Miguel, Quinta de São Gonçalves, 9500-343, Ponta Delgada, Portugal

Objectives: Photosensitivity (PTS) is induced by photodynamic agents (PA) circulating in the body, in presence of sunlight, those agents cause damages in skin cells. In Azores, PTS in cattle is mostly induced by Lantana camara and sporidesmin (SPD). SPD intoxication is more common at summer's end and autumn because it's when the sporulation of *Pithomyces chartarum* occurs. The aim of this study is determine the prevalence of cattle, slaughtered at abattoirs of São Miguel and Terceira Islands with skin lesions of photosensitivity (SLP), acute (aPTS) and chronic (hyperkeratosis-HPK), as well as the rates and causes of hepatic and carcasses rejection.

Materials and Methods: To prepare this study, data were collected from abattoirs in São Miguel Island (SMI) and in Terceira Island (TI) between 2008 and 2014 and, between 2005 and 2014, respectively. These data include information about ante mortem inspection (AMI), hepatic rejection (HR) and carcass inspection (CR) of cattle with SLP. Most of the time, data from the abattoirs were held in paper and were transferred to computer support to be worked in a best way. Dubious skin lesions and other skin lesions not linked to PTS and not confirmed by histopathological analyses were not considered.

Results: In abattoir of SMI, between 2008 and 2014, were slaughtered 151,790 cattle, 1,531 (1.01%) with SLP of these 53.76% with aPTS and 43.17% with HPK. October (14.34%) and September (11.79%) were the months with biggest aPTS input at abattoir, while November (11.95%) and October (10.89%) were the same for HPK. 32.2% of the cattle with SLP had their carcasses rejected, 22.99% presenting aPTS, 8.63% HPK and 0.59% both. Carcasses from cattle with aPTS were mostly rejected by acute PTS (35.8%) while in cattle with HPK (34.09%) were rejected mainly by urinary bladder neoplasia. Were rejected 93.54% of the 1,531 livers, 49.12% from cattle with aPTS and 41.48% from cattle with HPK. Independently of AMI and not taking in account the CR causes, the most frequent cause of HR was fibrosis/sclerosis (F/S)–31.03% of the 1,531 cattle. In abattoir of TI, between 2005 and 2014, were slaughtered 157,795 cattle, 751 (0.48%) with SLP of these 56.72% with aPTS and 41.68% with HPK. November and June with 18.31% each one were the months with biggest aPTS input at abattoir, while October (11.82%) and July (10.86%) were the same for HPK. 11.9% of the cattle with SLP had their carcasses rejected, 4.93% presenting aPTS, 6.79% HPK and 0.13% both. Carcasses from cattle with aPTS were mostly rejected by acute PTS (35.14%) while in cattle with HPK (49.02%) were mainly rejected by squamous cell carcinoma. Were rejected 78.3% of the 751 livers, 44.74% from cattle with aPTS and 32.22% from cattle with HPK. Independently of AMI the most frequent cause of HR was F/S–26.9% of the 751 cattle.

Conclusions: Prevalence of cattle with SLP is low, with most of cattle presenting aPTS at AMI. At SMI the months with biggest input numbers at abattoir of cattle with SLP belong to summer's end and autumn, while in IT this is partially true. The CR and HR rates differ a lot in both Islands partially because of lower number of slaughtered cattle at TI and the consequent lower speed of slaughterhouse line, allowing more time for remove improper areas of carcasses for

human consumption. The biggest input of cattle with SLP at abattoir in the specific period of year and F/S as the most frequent HR cause indicate that SPD intoxication can be the origin of PTS.

Classification of farm brucellosis status in function of the herd size, test characteristics, and cut-off used.Andres Gil¹Jose Piaggio^{1*}Bruno Lanfranco²Alicia von Gehlen¹Federico Fernandez³

¹Bioestadística, Facultad de Veterinaria - Uruguay, ²INIA, ³DGSG, MGAP, Montevideo, Uruguay

Objectives: Considering the herd size and the individual serological test characteristics, the goal of this study was to decide what would be the cut-off (number of seropositive animals) which is considered enough evidence to declare a farm as infected.

Materials and Methods: We stratified the farms population according to the susceptible population to analyze potential scenarios. Individual sensibility (Se) and specificity (Sp) was estimated with a simulation model that evaluate the use of 2 test in serial way. Herd specificity (HSp) was estimated for each scenario and different cut-off with the binomial distribution in a simulation model for a combined individual specificity of 0.9999 (0.9923-1.0) to compare the HSp values. Herd sensitivity was also calculate for the same scenarios using the hypergeometric distribution with an individual sensitivity estimated by the simulation of 0.9340 (0.9000-0.9577) and an intra-herd prevalence that ranged from 6% to 1%. A cut-off of 1 will ensure the maximum HSe, but the HSp goes down with the population sizes increase, with the consequent high proportion of false positives.

Results: In the Uruguayans' scenario with national cattle prevalence estimated in 0.15% and farms prevalence estimated in 0.75%, we recommended use different cut-off in function of the herd size. The recommended cut-offs are 1 serum positive cow in farms of up to 300 susceptible cattle (94-98% HSe and 96-100% HSp); 2 positive cows in farms between 301 and 500 (HSe > 89.5% and 98.5-99.6% HSp), and 4 positives cows in farms with more than 500 susceptible animals (95.8-100% HSe and HSp>94.499.8%). In addition, we recommended to no ignoring farms with any serological evidence of brucellosis; the veterinary services should investigated these herds to confirm or rule out the presence of infection.

Conclusions: In conclusion, in farms with large populations a single serum positive is not enough to confirm it as infected without any other evidence of infection. We propose that Legislation and eradication strategy should update with this information.

Occurrence of rabies in herbivores from Brazil - 2014Ellen E. Laurindo¹Elaine F. Sena²Joao H. Perotta³Ivan R. Barros Filho^{3,*}

¹ Ministry of Agriculture, Livestock and Supply of Brazil (MAPA),

²Ministry of Agriculture, Livestock and Supply of Brazil (MAPA),

³Veterinary Medicine, Federal University of Parana, Curitiba, Brazil

Objectives: In 1911, rabies transmitted by vampire bats to herbivores was first diagnosed in Brazil. Since 1967 the Ministry of Agriculture, Livestock and Supply (MAPA) establishing national programs to control the disease, in order to reduce its incidence in the country. Among the measures recommended in the program is control of the vampire bat population, vaccinating herbivores and passive surveillance of nervous diseases in herbivores by removal the Central Nervous System (CNS) and referral for diagnosis.

Materials and Methods: In this work, we analyze the Brazilian surveillance system for nervous diseases in herbivores (including cattle, small ruminants and equines), based on collection of data in official and accredited by MAPA laboratories for rabies diagnosis. Additionally, we used data provided by the regional offices of the Official Veterinary Service about species, aging and clinical findings. They were collected and analyzed Brazilian herd cattle data from the herd values indicated in vaccination campaigns for Food and Mouth Disease (FMD).

Results: Brazil has a population of 210,654,620 bovine heads divided into five regions: South (27,161,875), Southeast (38,100,368), Midwest (70,059,177), Northeast (29,179,081) and North (46,154,119). In 2014, 2449 CNS samples of herbivores were sent to laboratories for rabies diagnosis. Of these, 974 (39.7%) were positive for the indirect fluorescent antibody test (IFAT). The region that sent more samples for diagnosis was the Southeast (48.1%), followed by the South (22.5%) and Midwest (12.3%). The regions that showed greater number of positive samples over total positive were the Southeast, South and Midwest with 53.7% (523) 24.2% (236) and 7.1% (69), respectively. Regarding the representativeness of surveillance, it was considered the percentage of cattle in the region in relation to the national cattle herd and the percentage of exams within the total tests performed in the country. Thus, the region with the largest representation was the Southeast (with 18.1% of the national herd and 48.1% of total samples) and South (12.9% of the national herd and 22.5% of total samples). The Midwest, Northeast and North, which are located 145,392,377 head of cattle (representing 69% of the national herd), represented only 29.3% of the samples forwarded for rabies diagnosis,

Conclusions: The surveillance for rabies is carried out in Brazil uneven between regions. Considering the rabies zoonotic character, these differences observed in this study should be considered during the development of new control strategies of the disease in animals and in the protection of human health.

Text mining laboratory submission histories to further understand the epidemiology of Theileria associated bovine anaemia (TABA)

Kevin Lawrence ¹Sandra Forsyth ¹Bernie Vaatstra ²David Pulford

³Andrew McFadden ³William Pomroy ¹

¹IVABS, Massey University, ²Gribbles Veterinary, Palmerston North,

³MPI, Upper Hutt, New Zealand

Objectives: Since 2012 New Zealand has suffered a substantial epidemic of infectious bovine anaemia associated with *Theileria orientalis* (Ikeda), a tick-borne obligate intracellular haemoprotozoan

parasite. To date well over 1000 cattle farms in New Zealand have had at least one clinical case of *Theileria* associated bovine anaemia (TABA).

The objectives of this study were to analyse the submission histories for animals naturally infected with *T. orientalis* (Ikeda) and to contrast them for lightly and heavily parasitized cattle, for young and mature animals, for beef and dairy cattle and for severely anaemic, moderately anaemic and non-anaemic animals.

Materials and Methods: The data used in this analysis were collected over 2 years from 17/10/2012 to the 24/11/2014. The histories were taken from the laboratory submission forms for animals that met the case definition for molecular testing. Data were collated from the respective laboratory's submission forms and pre-processed into more precise clinical terminology where appropriate. These included concatenating words so that their context and meaning wasn't lost e.g. cows that were described as losing weight were grouped as "weightloss".

Since the clinical histories were the unit of interest then only one history was used per laboratory submission, even if multiple samples were included in that same laboratory submission. For those submissions that included multiple samples then the average PCV and average piroplasm count was used for categorisation of those histories. In text mining, each of the laboratory submission histories becomes a document in a corpus and from this corpus a term document matrix of the most commonly used words in the histories is prepared after removing unwanted text such as stop words and grammar. The frequency of text was displayed graphically using a word cloud, in which the size of font is proportional to the frequency of text such that the most common words used in the histories have the largest font. For comparison between categories bar plots were used to show the frequency of words with more than 10 occurrences in the histories.

Results: There were 227/281 (80.8%) unique laboratory submissions (276 blood samples) from Ikeda positive cattle, 15/281 (5.3%) from Ikeda negative cattle (19 blood samples) and 39/281 (13.9%) from non-Ikeda positive cattle (54 blood samples). The most commonly used clinical terms in sick Ikeda positive animals were jaundice (58/227), cow (53/227), anaemia (51/227), lethargic (47/227), pale mucous membranes (47/227) and tachycardia (37/227). However there were some marked differences recorded between age groups with jaundice most commonly seen in anaemic adult stock and rarely reported in anaemic young stock. Group problems were almost as frequently reported for calves as individual animals whereas individual sick cows were much more commonly reported for adults. Temperature was also more commonly recorded in young stock than for adults and affected animals were more likely to have normal temperatures than be pyrexia. Ticks were also more frequently recorded on the young stock than for other groups. For the non-anaemic cattle, weight loss, diarrhoea and off milk were most often recorded, with affected animals likely to show ill-thrift.

Conclusions: Practitioner observations are a valuable source of data that is rarely, if ever, used in understanding the epidemiology of a new disease. Methods need to be developed to better capture this data from laboratory submission forms.

Association of livestock owner, farm location and livestock movement on FMD in the endemic area with low immunity of animal population

Vilideth Souriya ¹Kittisak Ajariyakhajorn ²Thanis Damrongwatanapokin

³Chaidate Inchai ^{2*}

¹Department of Livestock and Fishery, Ministry of Agricultural and Forestry, Vientiane, Lao People's Democratic Republic, ²Veterinary Epidemiology and Animal Health Economics Group, Department of Veterinary Medicine, ³Veterinary Epidemiology and Animal Health Economics Group, Department of Veterinary Public Health, Chulalongkorn University, Bangkok, Thailand

Objectives: In Lao PDR, FMD is endemic and most farmers are small holders. Although FMD vaccination has been implemented and supported by OIE, a small number of animal population have been vaccinated. To provide a better knowledge of how to control FMD outbreaks and reduce the risk of FMD spread in Lao PDR as the area of low immunity of animal population, the objective of this study is to identify the risks in terms of livestock owners' characteristics, the number of livestock moved, spatial location, density of animal holders and animal population, and outbreak control strategies.

Materials and Methods: FMD outbreak information during 2011-2013 was provided by the Department of Livestock and Fishery, Lao PDR. Using a case-control design, this study employed a questionnaire and interview survey on livestock holders. Information on the important aspect of general information of livestock owners, FMD control and prevention strategies before and after outbreak, FMD emergency vaccination programs during outbreak, farm size, and farm types was captured. The household location and the elevation above the sea level were determined by a GPS tracker (Garmin GPS map 60csx, USA). The network data of animal movement between villages that surveyed in 2012 and matched with our survey villages in this study (29 villages) were analysed. A total of 434 households in 59 villages of 5 districts were interviewed and their data collected comprising 181 case households, 146 control households inside the outbreak villages and 107 control households outside the outbreak villages. Data from questionnaires and spatial data were analysed as independent variables in the logistic regression model using FMD occurrence at the household level as a dependent variable. Network parameters were analysed the association with FMD occurrence at the village level by non-parametric test.

Results: The results show that livestock owners who had knowledge about FMD before the outbreaks were able to better prevent their animals from FMD ($P < 0.01$) although they were less educated and administered less vaccination to their livestock. The livestock owners who were not Buddhist ($P < 0.05$) and younger ($P < 0.05$) in the outside of the outbreak villages were in a lower risk than the owners inside the outbreak villages. The livestock households in the community closer to a main road and lower elevation within a higher number of livestock were at higher risk to developing FMD ($P < 0.01$). Moreover, the information of network parameters at the village level indicated that the villages with high movements of livestock were at high risk of FMD ($P < 0.05$).

Conclusions: In conclusion, this study clearly indicated the association of owners' knowledge about FMD and the community areas with high density of movement on FMD occurrence. The households far away from the centre of community had a decreased probability of FMD occurrence. The owners' awareness is also important to reducing FMD. To prevent FMD effectively in the area with low immunity of animal population, the location of farms should be advised being away from community and livestock owners should be trained and educated in biosecurity to prevent FMD outbreak.

Comments: However, until now, there are still a limited number of livestock that were vaccinated and low levels of biosecurity to prevent FMD within villages. The study to increase immunity and improve the biosecurity at the village level to prevent and control FMD represents a challenging task for future investigation.

Study Of The Serological Response Of Bovine Leptospirosis In Cases Of Abortion In Uruguay

Alejandra Suanes¹*Ximena Salaberry¹Jose Piaggio²Alicia von Gehlen¹Alberto Mortola¹

¹Bacteriology, DILAVE, Ministry Agriculture and livestock,

²Epidemiology, Ministry Agriculture and livestock, Montevideo, Uruguay

Objectives: Leptospirosis is a bacterial disease caused by pathogens from the genus *Leptospira*. It is a zoonosis of worldwide distribution, that affects most domestic mammals, and wild animals. The disease is considered an occupational high-risk disease for man, who acts as an accidental and terminal host. In cattle, the disease causes great economic losses due to: abortions, infertility, decreased milk production and calves may die during infection. The aim is to study the serological response against leptospirosis in cattle from abortion outbreaks.

Materials and Methods: For the present study the database of samples sent to the Veterinary Laboratories Division of the Ministry of Agriculture and Fisheries (DILAVE) in the period from 2008 to 2014 for the bovine species was analyzed. A total of 10,540 sera samples from 1,483 farms with a history of abortion were analyzed by the microscopic agglutination test (MAT). Sera were checked against 8 serovars (Bratislava, canicola, Grippotyphosa, Icterohaemorrhagiae, Pomona, Hardjo type Hardjoprajitno, Hardjo type hardjobovis and Wolfii). It started with a titer cut-off of 1/200. In positive samples to 1/200, successive dilutions in base of two were carried out until 1/6,400. The data was also stratified by time of year and geographical distribution. The results were analyzed with software STATA 15.0.

Results: The 50.46% of the samples with a history of abortion were positive by MAT starting from a titer of 1/200. Forty seven percent of the farms were seropositive. The data shows that the less reactive serovars throughout the period studied were Canicola, Bratislava, Grippotyphosa and Icterohaemorrhagiae with minor proportions of positive 6% for the four analyzed serovars. For the serovars of the serogroups Pomona and Sejroe (Hardjoprajitno, hardjobovis, Wolfii) you can see a high proportion of positive throughout the study period. For the serovar Pomona an average percentage of 27% was observed, for serogroup Sejroe 32%. It was also demonstrated by the MAT test that there was a 76% of cross reactions between serovars of the serogroup Sejroe. Taking all serovars as a whole, a homogeneous distribution is observed in the studied years, noticing a relative increase in 2009 and a reduction in 2014. There was no difference between the seasons. The geographical distribution was 57-59% for North, South and West and less than 45% for the eastern region of the country.

Conclusions: The data analyzed in the study period (2008-2014) shows that the serovars with more presence with a serological response in the cattle population of Uruguay are: Hardjo with his two biotypes. Hardjobovis and Hardjoprajitno, Wolfii and Pomona. The variations between years can be explained by climate and seasonal influence of the disease. Uruguay disease occurs throughout the year. It is endemic, the annual incidence may vary depending on the weather. MAT is a good test to diagnose positive farms with history of abortions to Leptospirosis.

Comparative analysis of Brazil and USA bovine spongiform encephalopathy (BSE) national monitoring systems and the challenge of atypical BSE

Ellen E. Laurindo¹ Elaine F. Sena² Joao H. Perotta³ Ivan R. Barros Filho^{3,*}

¹ Ministry of Agriculture, Livestock and Supply of Brazil (MAPA),

² Ministry of Agriculture, Livestock and Supply of Brazil (MAPA),

³ Veterinary Medicine, Federal University of Parana, Curitiba, Brazil

Objectives: Although the Bovine Spongiform Encephalopathy (BSE) is under control, other forms of the disease have been reported, initially in Europe, and the knowledge about their impact on public health remains uncertain. In compliance with this importance in international trade, the World Animal Health Organization recommends actions aimed at mitigating the risk of spread the BSE around the world. Brazil and the United States are countries with large commercial cattle herds, and in both there was only the occurrence of atypical BSE indigenous cases.

Materials and Methods: In this work, the BSE monitoring systems were analyzed in these countries, based on regulatory laws, legal support of health programs, surveillance strategies and emergency plans of the official veterinarian services and this data. They were also evaluated and compared them to the animal health care systems, including laboratory capacity, participation of veterinarians from the private sector in animal health protection actions and number of veterinary medicine educational institutions of each country.

Results: We founded that both systems meet the guidelines of the World Organization for Animal Health. However, this same organization does not call for actions to prevent or control that specifically address the atypical BSE, as the target of the surveillance are ruminants with the presentation of the classic picture of the disease. In this sense, is necessary the reassessment of priorities and give more importance to all other surveillance categories (older and fallen bovines and those destined to abattoirs).

Conclusions: Regarding the Brazilian surveillance system, it can be concluded that there is need for profound changes in the packaging system samples and laboratory tests, because the current system is focused on the diagnosis of classical form of BSE. We concluded that the BSE monitoring system in Brazil is more focused on animal health, while the US system is aimed the meat consumer protection. The adjustments identified in this work are needed for Brazilian system reaches a level of excellence and to provide more security for consumers of Brazilian meat products.

Objectives: Bovine Respiratory Diseases (BRD) are a major pathological complex in cattle, with significant impact on farm economical results. The pathogen agents responsible for these disorders are essentially viruses and bacteria, often associated on the field. Polymerase Chain Reaction (PCR) is a major technique of diagnosis, due to its better detection performance in comparison with traditional bacteriological methods. The objective of this study was to determine the field prevalence of BRD pathogens using the PCR technique in France.

Materials and Methods: Since December 2012, 2 major laboratories for diagnosis located respectively in Nièvre and Ile et Vilaine departments participated in this field BRD epidemiological survey, with support from MSD Animal Health. The sampled animals, from a few days to several months old, had generally clinical symptoms of respiratory disease in early evolution. After sampling by the vets either from deep nasal swabs (3 swabs per farm) (80% of all samples) or trans-tracheal fluids (<10%) or pulmonary tissues of animals, PCR was performed after mixing maximum 3 samples from the same BRD outbreak in the same farm. A total of 648 individual viral and bacterial diagnosis were analyzed.

Results: In the present study, a grand majority of the analysis showed the presence of bacteria with more than 80% of the samples positive for *Pasteurella multocida* (up to 85% associated with another pathogen) and 46% of samples positive to *Mannheimia haemolytica*. In the other hand, *Histophilus somni* and *Mycoplasma bovis* were found to a lesser degree. Regarding BRD viruses, Bovine Respiratory Syncytial Virus (BRSV) was detected in less than one third of all cases, half in association with *M. haemolytica*.

Conclusions: This prevalence study in French field farms confirmed the presence of the 2 major BRD pathogens: 1) *M. haemolytica*, for which one could think that it could be overestimated because of the sampling technique (nasal swabs) and the testing method (PCR). But former studies showed a correlation between nasal swabs and trans-tracheal aspiration on pooled samples (3 particularly), and 2) BRSV, for which the prevalence of 30% could seem to be low.

Underlying mutation(s) for a deformed cleft pallet in a Holstein-Friesian sire familyMichelle Judge¹·Brian Kirkpatrick²·Donagh Berry¹¹Teagasc, Fermoy, Co. Cork, Ireland, ²University of Wisconsin-Madison, Madison, Wisconsin, United States

Objectives: A deformed cleft pallet phenotype was detected among a small proportion of the offspring of a phenotypically normal Holstein-Friesian bull. The objective of the present study was to test the hypothesis of a single gene controlling the phenotype and to map the gene.

Materials and Methods: Pedigree analysis of affected calves was undertaken. Bovine50 Beadchip genotypes (i.e., 54,001 single nucleotide polymorphisms; SNPs) were available on the phenotypically normal Holstein-Friesian sire and high density genotypes (i.e., 777,962 SNPs) were available on both his affected (n=23) non-affected (n=44) paternal half-sib progeny. The genotypes of each individual were phased, and were subsequently used to predict paternally inherited haplotypes in the offspring. The hypothesis of segregation of a single gene was tested and mapping of the gene was performed by linkage analysis using two alternative approaches. In the first approach, the association of the paternally inherited haplotype with the affected phenotype utilised both affected and non-affected offspring (n=67) in a typical linkage analysis. In the second approach, only offspring with the affected phenotype were used (n=23), thus testing the deviation of the paternal haplotype inheritance from the expectation of equal representation of alternative haplotypes under the null hypothesis of no association.

Results: Affected calves did not display obvious inbreeding to a common ancestor thus essentially ruling out the likelihood of a recessive mutation being the likely causative factor. Linkage analysis results, based on all offspring, resulted in significant associations for regions on both distal BTA13 ($p < 2 \times 10^{-5}$) and BTA17 ($p < 2 \times 10^{-4}$). When only including affected offspring in linkage analysis, the significance of the association observed on BTA13 increased considerably ($p < 1 \times 10^{-24}$) and became more obvious than on BTA17.

Conclusions: Affected calves did not display a common ancestor suggesting that the causative allele was not a rare recessive. The only commonality among pedigrees was the sire, and his normal phenotype suggests that either incomplete dominance of an allele or a mosaic mutation are the likely modes of gene action; the mutation(s) appears to reside on distal BTA13. Whole genome sequence of two affected calves will be undertaken in future investigations.

Genetics and Breeding

P04-004-028

Sire prevalence of Bovine Viral Diarrhoea infection in Irish cattleSiobhán C. Ring^{1,2}·Michael L. Doherty²·David A. Graham³·Margaret M. Kelleher⁴·Donagh P. Berry¹¹Animal & Grassland Research and Innovation Centre, Teagasc, Moorepark, Co. Cork, ²School of Veterinary Medicine, UCD, Belfield, Dublin 4, ³Animal Health Ireland, Main Street, Carrick on Shannon, Leitrim, ⁴Irish Cattle Breeding Federation, Highfield House, Bandon, Co. Cork, Ireland

Objectives: Bovine viral diarrhoea (BVD) is one of the most important infectious diseases affecting the productivity and international competitiveness of the Irish livestock industry. Production losses associated with BVD cost dairy and beef producers an estimated €102 m per annum. The objective of this study was to quantify the contribution of genetics to differences in resistance to BVD in Irish dairy and beef cattle. Results will be useful in determining the feasibility of genetic selection of cattle for increased resistance to BVD.

Materials and Methods: BVD virus test results from the national BVD eradication programme were available for 4,519,810 calves in 82,585 herds between the years 2012 and 2015, inclusive. BVD tests were undertaken using either an enzyme-linked immunosorbent assay or reverse transcription polymerase chain reaction test. Test results were classified as negative or positive according to the kit manufacturers' guidelines. Animals were defined as persistently infected (PI) or non-persistently infected (non-PI) based on either an animal's own test result(s) or its progeny/dam test result(s). To maximize the likelihood of equal lifetime exposure to BVD virus between herd-mates, only dams that remained in the herd since birth, with known BVD infection status (i.e., PI or non-PI) for the dam and her progeny were retained. Exposure of a dam and her progeny to BVD virus was defined by the birth of a contemporary PI calf/calves; this was undertaken for primiparous and multiparous cows separately. Only data from singleton calves with a known sire in exposure groups with ≥ 5 calves were retained. After all data edits, 79,618 calves from 3,530 exposure groups in 2,953 herds remained. The mean prevalence of BVD in the progeny of individual sires was estimated for sires with > 50 progeny in > 10 herds. Also, the mean prevalence of BVD in the grand-progeny of individual maternal grandsires was estimated for maternal grandsires, that produced non-PI female offspring with > 50 grand-progeny in > 10 herds. The heritability of BVD is currently being estimated.

Results: The overall prevalence of PI calves in the final dataset was 5.83%; this is not indicative of the national population as the dataset was edited to only include animals with maximum potential of exposure to BVD virus; the prevalence of PI calves in this study prior to elimination of animals not exposed to BVD virus was 0.36%. The mean prevalence of PI calves per sire (n=171) ranged from 0 to 0.23. This indicates that some sires did not produce PI offspring, while other bulls sired up to 23% PI offspring; all calves were born in close proximity in time to a contemporary PI calf. Furthermore, the mean prevalence of PI calves per maternal grandsire (n=191) ranged from 0 to 0.15. This indicates that some maternal grandsires did not produce any PI grand-progeny, while other grandsires produced up to 15% PI grand-progeny.

Conclusions: This preliminary study indicates that the prevalence of BVD PI calves differs between paternal half-sibs as well as among grand-progeny indicating underlying genetic variability in susceptibility to BVD. Heritability estimates will aid in quantifying this genetic variation.

Genetics and Breeding

Chronic diarrhoea associated with Cholesterol Deficiency in Holstein Calves: A Case SeriesThomas Mock¹·Kemal Mehinagic²·Fiona Menzi³·Cord Droegemueller³·Mireille Meylan¹·Nadine Regenscheit²¹Clinic for Ruminants, ²Institute of Animal Pathology, ³Institute of Genetics, Vetsuisse Faculty, University of Berne, 3012 Bern, Switzerland

Objectives: A new inherited autosomal recessive genetic defect in Holstein calves, named cholesterol deficiency (CD), has been reported recently in Germany. The Canadian sire MAUGHLIN STORM has been detected as the first carrier bull. Homozygous calves show clinical signs of diarrhea unresponsive to treatment and failure to thrive, have very low blood cholesterol and triglyceride concentrations, and usually die within the first six months of life. The aim of the present study is to describe the clinical picture, necropsy findings and the genetic defect causing this new disease entity.

Materials and Methods: Five calves with a history of failure to thrive and intermittent diarrhea unresponsive to treatment were referred to the Clinic for Ruminants of the Vetsuisse Faculty in Berne. A full clinical examination and measurements of cholesterol and triglycerides were performed for all calves, as well as a complete blood count and blood chemistry profile for three calves. Faecal samples were sent for viral, bacterial and parasitological analysis for the most common pathogens causing calf diarrhea (rotavirus, coronavirus, cryptosporidia, coccidia, *E. coli* and *Salmonella* spp). The five calves were euthanized and immediately necropsied. Macroscopical and histological examinations were performed. A recently developed PCR-based direct gene test was applied to determine the genotype using genomic DNA extracted from EDTA blood samples.

Results: All five affected Holstein calves were inbred to the assumed founder MAUGHLIN STORM. The mean age of the calves was 86 days (min-max: 18-224 days). All calves were poorly developed and underweight, but otherwise in a good to moderately reduced general condition, mostly with a good appetite. They showed intermittently soft to liquid faeces. Physical examination was otherwise without abnormalities. The concentrations of cholesterol (mean: 0.19 mmol/L, min-max: 0.09-0.24 mmol/L) and triglycerides (mean: 0.04 mmol/L; min-max: 0.04-0.06 mmol/L) were distinctly below the values obtained from five healthy Holstein controls of comparable age (min-max: cholesterol: 1.79-3.20 mmol/L; triglycerides: 0.27-0.43 mmol/L). The blood work of one calf showed additionally a slight anaemia and a low selenium concentration. Coprological examination revealed the presence of *Cryptosporidium parvum* and *Eimeria bovis* oocysts in one calf each. At necropsy, the small and large intestines were filled with liquid, partially foamy and mucinous content, and the wall of the small intestine appeared diffusely oedematous. Histological examination of the small intestine revealed enterocytes containing large amounts of optically empty, intracytoplasmic vacuoles, ranging from 2-20 µm in diameter which stained positive in the Sudan stain for lipids. The genetic analysis revealed that all calves were homozygous for the responsible APOB (apolipoprotein B) gene mutation shown to be associated with cholesterol deficiency.

Conclusions: The clinical presentation and necropsy findings associated with CD had not been described in detail to date. A clinical suspicion in Holstein calves can be confirmed using the new gene test. This new diagnostic tool will allow for a reduction of unnecessary costs of treatment, use of antibiotics and time-consuming care of affected animals, and targeted eradication of the causative mutation from the Holstein population. Since the frequency of the deleterious mutation in the global Holstein population is supposed to be high, this disease has a significant impact on the rearing success of calves.

Targeted DNA sequencing of the expanded β-defensin gene repertoire in bulls of high and low fertility

Emma Finlay¹ Matthew S. McCabe¹ Paul Cormican¹ Cliona O'Farrelly² Kieran Meade¹

¹Animal and Bioscience Research Department, Teagasc, Dunsany, Co Meath, ²School of Biochemistry & Immunology, Trinity College Dublin, Dublin, Ireland

Objectives: Host Defence Peptides, specifically β-defensins, have been shown to influence fertility across a range of mammalian species, including in mice and in men. However, association between genetic variation in the expanded suite of 57 bovine defensin genes and fertility in bulls has not been previously investigated. Building on our discovery of a novel β-defensin gene cluster in the bovine genome, we used a targeted DNA sequencing approach to capture diversity at all known defensins in bulls of known fertility status used for artificial insemination (AI) in Ireland.

Materials and Methods: Bulls divergent in pregnancy rate data (>1000 AI records) were identified and selected for targeted DNA sequencing. DNA baits were designed to capture complete gene sequences plus 1Kb upstream, covering 235 kb of the 387 kb β-defensin gene clusters genes, when repetitive regions were excluded. DNA was extracted from sperm of 144 bulls representing the extremes of fertility, libraries prepared using Illumina TruSeq, captured with the Nimblegen SeqCap EZSeq custom capture and sequenced on a MiSeq. Reads were aligned to the reference genome and variants identified following the GATK Best Practice pipeline and quality filtered. An association study between the bull fertility phenotype using an adjusted animal model and the variant genotypes was performed.

Results: Targeted regions had an average coverage of 197 X. Following editing and quality control, 2836 SNPs were examined, 37% of which are novel and have not been previously described in cattle. 7.5% of SNPs are found in gene exons, and 25%, 23% and 22.5% are upstream, intronic, or downstream, respectively. 702 SNPs were breed specific and some chromosomal regions show runs of breed-specific variants. A haplotype containing 94 SNPs covering ~138kb and found in 9 highly fertile bulls was found to be significantly associated with fertility. Functional assessment of these SNPs in sperm from high and low fertility bulls is currently ongoing.

Conclusions: This is the first comprehensive analysis of sequence variation present in these bovine genes which play critical roles in immunity and fertility. A targeted sequencing discovery of β-defensin diversity in bulls used in AI identified a haplotype spanning a region containing several β-defensin genes associated with fertility. The region includes the bovine homologue of defensin 126 which has been shown to play a role in male fertility in humans, macaques and rodents. These SNPs have been added to the International Beef and Dairy SNP chip to validate their association with fertility (and potentially other) phenotypes of economic interest.

Landscape geography of locally adapted sheep in Brazil using SNP markers

Concepta Mcmanus¹ Samuel R. Paiva² Potira M. Hermuche¹ José L. Jivago¹ Alexandre Caetano²

¹University of Brasilia, ²Embrapa Genetic Resources and Biotechnology, Brasilia, Brazil

Objectives: Genetic landscape describe and explain how the landscape and its components affect the genetic variation of populations animals and plants. The goal of this investigation was to explore patterns of spatial genetic structure in locally adapted sheep breeds in Brazil.

Materials and Methods: A total of 215 individuals from eight different locally adapted Brazilian breeds were genotyped using the 50KSheepSNPChip. All samples were georeferenced and genotyped with the Illumina Ovine SNP50 BeadChip. Data quality control and pruning were performed with Golden Helix SVS v7. Markers with call rates <98% and minor allele frequency (MAF) values <0.1 were removed. Non-autosomal markers and all markers in linkage disequilibrium (using r^2 greater than 0.05 (indep-pairwise 50: 5: 0.05) were excluded using Plink. The window size in SNPs was 50, the number of SNPs to shift the window at each step was 5 and 0.05 represents the r^2 threshold. The final dataset contained 23,613 SNPs.

All data sets were initially analyzed via Mantel tests and spatial autocorrelation as implemented in Alleles In Space (AIS; Miller, 2005). In Mantel tests, 5000 randomization replicates were used to evaluate the significance of correlations between $p/(1-p)$ or $D/(1-D)$ and the natural logarithm of geographic distance. For spatial autocorrelation analyses, distances were varied from 5 to 20 classes. Data were analyzed using the Genetic Landscape Shape procedure in AIS. This procedure yields an interpolation-based graphical depiction of spatial genetic structure and diversity across landscapes that can be used to identify genetic discontinuities or landscape regions where relatively high or low genetic distances exist. The procedure was performed by initially generating a Delaunay triangulation-based connectivity network for each species' set of sampling locations and 1000 permutations performed.

Results: The correlation of genetic and geographical distances using the Mantel test was -.0485. The probability of observing a correlation greater than or equal to observed was $P = .873$ and less than or equal to observed = .127. This is probably due to high individual variation within breeds and locations sampled.

The average pairwise genetic distance from the full data set was 0.567 using the Spatial Autocorrelation Test. From the analysis of full distogram: $V = .00136$ with a probability of observing a random value of $V \geq$ observed V by chance had a $P = .25800$. The Allelic Aggregate Index Analysis showed no clear pattern in genetic discontinuity with sheep breeds reared in Brazil with a low number of classes, but with higher number of classes, a tendency for genetic discontinuities between 188 and 938km was noticed.

The interpolation of the Genetic Landscape Shape shows high genetic discontinuities in the northeast and south of the country

Monmonier Maximum Distance Algorithm results indicates an initial subdivision separating the Crioula Lanada from Santa Catarina from the others and then the Pantaneira population from the others. Further subdivision separates hair sheep in Northeastern region including the states of Ceara, Paraiba and Maranhão with the breeds Morada Nova, Somalis Brasileiro and Santa Ines. Little differentiation is seen in the Centerwest region, which may indicate that although samples collected were from purebred animals, these may have already suffered some level of miscegenation as sheep breeding in this region is relatively recent.

Conclusions: High genetic differentiation is seen in the Northeast and Southern regions of Brazil. The results indicate a minimum distance of 188km between collection sites for future sampling, including the Southeast region.

Defensin Gene Variation and Fertility in Irish Bulls

Ronan Whiston ^{1,2}; Kieran G. Meade ¹; Emma Finlay ¹; Cliona O'Farrelly ²

¹Animal and Bioscience Research Department, Teagasc, Trim, Meath,

²Comparative Immunology Group, Trinity Biomedical Science Institute, Dublin 2, Ireland

Objectives: To address fertility in the Irish national herd, the focus, in literature, to date has been on female fertility traits. In Holstein-Friesian, pregnancy rates can fall as low as 25% with low fertility bulls, yet no single diagnostic test can accurately predict fertility in bulls, thereby limiting genetic gain for male fertility. Mutations in β -defensin genes have been associated with fertility in multiple species including humans, but have not previously been investigated in cattle. In order to identify genetic variants affecting male fertility, whole-exome sequencing and targeted β -defensin gene sequencing of Irish AI bulls was performed.

Materials and Methods: Bulls divergent in Pregnancy Rate (PR) data and an adjusted animal model (a PR model which also includes environmental factors), were identified and 24 bulls with extreme fertility were selected for sequencing. DNA baits were custom-designed to capture all exons annotated in the bovine genome (plus 100bp of 5'UTR) as well as complete β -defensin gene sequences (plus 1kb of 5'UTR). DNA was extracted and libraries were prepared with Illumina TruSeq Nano kits. DNA was captured using Nimblegen's SeqCap EZ developer kit, and sequenced on a HiSeq2500 for exome libraries, and MiSeq for β -defensin libraries. Reads were quality filtered, aligned to the bovine UMD3.1 reference genome, and genetic variants were called via GATK's HaplotypeCaller, following the best practice pipeline. Variants were annotated and an association of variants with the adjusted animal model phenotype was performed.

Results: Mean target coverage of whole-exome regions was 18.5X, with 95% being covered at 2X depth and 69% of the exome covered at a depth of 10X. Variant calling identified 258,870 SNPs, 12,124 insertions and 13,048 deletions, following variant filtration in 24 bulls. Of these, 38% were located within exons and 2.5% were located within the 5'UTR. Of the exon mutations, 47% were non-synonymous, 43% synonymous and 1.6% resulted in a frameshift mutation. Variants with a frequency difference >25% and which had a call rate of at least 80% were plotted, resulting in 3,314 variants divergent between high and low fertility bulls. Association analysis via the R bioconductor package, GenABEL, identified 405 SNPs significantly associated with fertility phenotype (unadjusted $P < 0.01$). Of the top 20 most significantly associated SNPs, 6 were non-synonymous, 5 synonymous, 1 stop gained, and 8 were located in regulatory regions upstream and downstream. The SNP which was most significantly associated with the adjusted animal model phenotype was located in the 3'UTR of the Progesterone Receptor Membrane Component 1 gene, PGRMC1, the human homolog of which functions in steroid signalling, p450 activation and drug metabolism.

Conclusions: In conclusion, 3,314 variants have been identified in AI bulls with extreme deviation for Pregnancy Rate. 405 variants have been associated with an adjusted animal model fertility phenotype and from these variants, discovered in bulls of divergent phenotypes, 669 have been added to the International Dairy and Beef SNP chip (v3) used for national cattle genotyping and will determine their association with fertility and health phenotypes in large numbers of independent samples.

Geographical distribution of zebu breeds in Brazil and their relation to climatic, environmental factors

Paulo Ricardo M. Lima¹Vanessa Peripolli¹Candice B. Tanure¹Luiza Seixas¹Conceita Mcmanus^{1*}

¹University of Brasilia, Brasilia, Brazil

Objectives: The objective of the present study was to evaluate the distribution of different zebu breeds in Brazil, correlating their occurrence with climate variables, environmental and human development indicators.

Materials and Methods: The location of all pure herds of zebu cattle in Brazil were made available the ABCZ (Brazilian Association of Zebu Breeders), classified as meat type (Brahman, Polled Brahman, Nelore, Polled Nelore, imported Nelore and Tabapuã), milk type (Gir and Polled Gir), and dual purpose (Guzerá, Indubrasil, Polled Indubrasil, Red Sindi and Polled Red Sindi) being spacialized in ArcGIS® program along with climate conditions (precipitation, Normalized Difference Vegetation Index - NDVI, relative humidity, temperature, Temperature Humidity Index - THI), environmental (altitude, rivers and streams protected by forests, rivers and streams without forest protection, establishments with and without family agriculture, areas planted with forage, degraded planted pastures, planted grazing areas in good condition, areas with agrosilvopastoral systems, areas with rotational pasture handling), and human development indicators (Human development Index - longevity and Human Development Index - education). The statistical analysis included an analyses of variance and logistic regression in SAS® v.9.3 software.

Results: The highest concentration of zebu animals is in the Midwest region of Brazil, followed by the Southeast and North, where Pará state stands out. The South region there was a lower frequency of zebu breeds as these states traditionally use European breeds. In the states in the Northeast the lower distribution of zebu cattle in the region compared to other locations is probably due to its extreme climate, highly susceptible to long periods of high temperatures and absence of rainfall, which directly affects local livestock. The meat breeds were evenly spread throughout the country, probably due to them fitness for meat production, in particular the Nelore. The meat breeds present differed due to environmental variables, showing a higher incidence with increased rainfall, NDVI, temperature, relative humidity, THI and solar radiation, as well as the environmental variables: establishments without family agriculture and rivers and streams protected forests. The dual purpose and dairy breeds, showed significant effects of areas planted with forage, agrosilvopastoral systems and rotational pasture management, indicating a dependency of dairy production on crops for nutrition to support milk yield. The Gir breed, the only with exclusive dairy exploration, showed herds in regions with higher family agriculture, characterized by small to medium farms, and in regions with higher altitude.

Conclusions: The geographical distribution of the various zebu breeds may contribute to better understanding of their adaptation to the environment, assisting in the development of environmental indices, possible corrections of production management, genetic evaluations, breed choice for certain environments, among others.

Genetic parameters for *Fasciola hepatica* infection in dairy and beef cows

Alan J. Twomey^{1,2*}Michael L. Doherty³Rebecca I. Carroll⁴David A. Graham⁴Jennifer C. McClure⁵Donagh P. Berry¹

¹Animal & Grassland Research and Innovation Centre, Teagasc, Moorepark, Co. Cork, ²School of Agriculture, Food Science & Veterinary Medicine, ³School of Veterinary Medicine, University College Dublin, Belfield, Dublin 4, ⁴Animal Health Ireland, Main Street, Carrick on Shannon, Leitrim, ⁵Irish Cattle Breeding Federation, Highfield House, Bandon, Co.Cork, Ireland

Objectives: *Fasciola hepatica* (liver fluke) is a helminth parasite of economic importance to the cattle industry globally. A high prevalence of *F. hepatica* has been reported in herds across the world. Genetic variability for a range of cattle diseases is known to exist. However, to our knowledge, no genetic parameter estimates exist for susceptibility to *F. hepatica* in cattle. The objective of this study was to estimate genetic parameters for susceptibility to *F. hepatica* infection in Irish dairy and beef cattle.

Materials and Methods: In Ireland, cattle livers are inspected for *F. hepatica* at slaughter. Damaged livers are diagnosed as either "live *F. hepatica* observed" or "*F. hepatica* damaged without the presence of live *F. hepatica*". Only animals with a high likelihood of exposure to *F. hepatica* infection were considered. Cows were deemed to have a high likelihood of exposure if they resided in a herd within a period 100 days flanking the date of slaughter of a cow herd-mate with recorded live *F. hepatica* at slaughter. When a cow with *F. hepatica* damage without the presence of live *F. hepatica* was slaughtered, herd-mates that were born into that herd within 100 days of that cow, and remained within that herd until at least 100 days prior to the diagnosis of that herd-mate, were also assumed exposed. Cows deemed exposed, with a known sire and no herd movement after 90 days of age were retained. Contemporary groups of herd-year-season of final calving date of <4 cows were discarded. The final dataset consisted of 16,734 cows from 2,865 contemporary groups. (Co)variance components for liver fluke were estimated using linear mixed models. Fixed effects included in the model were contemporary group, heterosis, recombination loss, parity, age within parity, and abattoir by slaughter date. Random effects were animal genetic effects and residual effect. The pedigree of each animal in the analysis was traced back to the founder population which was allocated to genetic groups. The mean prevalence of *F. hepatica* liver damage per paternal half-sib group was quantified for sires with ≥ 30 progeny in ≥ 10 herds.

Results: The prevalence of *F. hepatica* damage in 16,734 cows included in the analysis was 47%; this should not be taken to represent a national statistic as the data were highly edited for genetic analysis. The heritability (standard error in parenthesis) of *F. hepatica* liver damage was 0.028 (0.0117). The genetic standard deviation for *F. hepatica* liver damage was 0.068 units. The mean prevalence of *F. hepatica* liver damage per sire (n=78) ranged from 14% to 71%. This signifies that some sires had only 14% of their progeny positive for *F. hepatica* liver damage while other sires had 71% of their progeny positive for *F. hepatica* liver damage

Conclusions: Heritable genetic variation exists in susceptibility to *F. hepatica* liver damage. *F. hepatica* liver damage is routinely diagnosed in the majority of Irish abattoirs; therefore national genetic evaluations for *F. hepatica* susceptibility are possible.

P04-004-035

Geographical evaluation of the Brazilian genetic resource conservation programConcepta Mcmanus¹ Potira M. Hermuche¹ Luiz Felipe Ramos Carvalho² Bruno S. L. Dallago¹ José L. Jivago¹ Samuel R. Paiva³¹University of Brasilia, ²Ministerio da Agricultura Pecuaria e Abastecimento, ³Embrapa Genetic Resources and Biotechnology, Brasilia, Brazil**Objectives:** The aim of this work was validate the integration of spatial (georeferenced) and genetic data regarding local of origin from 3518 DNA samples from 17 different genetic groups or breeds of sheep in the Brazilian Germplasm bank**Materials and Methods:** Samples of sheep in the Germplasm Bank of Embrapa Genetic Resources and Biotechnology was geo-referenced using a geographic information system (software ArcGIS 9.3).

DNA was extracted from 383 individuals and 10 breeds and quantified by spectrophotometry. 22 microsatellite markers were optimized: OarFCB20, ILSTS05, OarFCB48, ILSTS11, ILSTS87, INRA35, INRA05, INRA63, OarAE129, OarFCB304, OMHC1, OarHH35, OarJMP29, INRA23, MAF65, MAF214, BM827, HUIJ616, OarCP20, INRABERN172, SRCSP05, BM6526 were chosen due to their availability and were on the list recommended by FAO

Genotyping including intra-breed and intra-populational variability parameters such as number of effective alleles per locus, allelic diversity, number of diagnostic (specific) alleles per breed, observed (Ho) and expected (He) heterozygosity under Hardy-Weinberg (EHW) equilibrium, polymorphic information content (PIC) and fixation index (Fis) or inbreeding coefficient.

Distances between DNA collection site and the conservation nucleus responsible for the collection were calculated and submitted to an analysis of variance to see if there was a difference in the distances per breed and per conservation nucleus.

Results: Data from the analysis of molecular variance (AMOVA) show that 12.87% of total observed variance ($p < 0.001$) was due to inter-breed differences. Intra-breed variability showed that the Santa Inês breed had highest heterozygosity values as well as mean number of alleles per locus (0.7580 and 8.39 respectively) while the Somali and Corriedale breeds had the lowest values for these indices respectively (0.5752 and 4.22). With the exception of the Hampshire, all breeds had inbreeding coefficients (F_{IS}) less than 10%.

Inter-breed results and AMOVA suggest small genetic differences between sheep breeds in Brazil. The structure analysis shows good separation of the different breeds with subdivisions in the Santa Inês and Morada Nova breeds. The mean genetic distance between pairs in the full data bank using microsatellite data was 0.67 and was not affected by the geographical distance between the sampling sites, independent of breed.

The group of data showed a Moran index (spatial autocorrelation) of -0.063. The correlogram shows seven distance classes (in degrees) from the northern most point (OMN_VE collected in Sobral, Ceará state). The autocorrelation is low with a high coefficient of variation. This shows high diversity between samples, even those that are collected close to each other. Therefore they may be considered independent samples, emphasizing the unicity of the breeds. The spatial autocorrelation between geographic and genetic distance is low, i.e. although they are spatially close, the breeds are genetically distinct from each other.

Conclusions: The Animal Germplasm Bank has been fulfilling its role

of storing the genetic material of endangered breeds. There is need to update the core conservation as well as to collect samples at other locations outside the core for some breeds. Information is needed on the distribution of animals by breed in the country to improve and consolidate the sampling germplasm bank with national coverage for sheep in Brazil.

Genetics and Breeding

P04-004-036

Effect of β -defensin 126 haplotypes on the ability of bovine sperm to bind to bovine oviductal epithelial cells (BOEC) in vitroAlan Lyons¹ Emma Finlay² Pat Lonergan³ Kieran G. Meade² Sean Fair⁴¹Department of Life Sciences, Faculty of Science and Engineering, University of Limerick, Limerick, ²Animal & Grassland Research and Innovation Centre, Teagasc, Grange, Meath, ³School of Agriculture and Food Science, DCU, Dublin, ⁴Department of Life Sciences, University of Limerick, Limerick, Ireland**Objectives:** We have recently discovered a cluster of 19 novel β -defensin genes, some of which are exclusively expressed in the epididymis of the bull and in the oviduct of the cow. Previous studies in other species (humans, macaques and rodents) have suggested a role for β -defensins in mediating sperm function and/or immune-protection of the sperm in the female tract and thus they are likely to play a key role in the successful establishment of pregnancy. The objective of this study was to functionally characterize the relationship between β -defensin 126 haplotype in bulls and the ability of sperm to bind to bovine oviductal cells (BOEC) in vitro.**Materials and Methods:** Adjusted bull fertility phenotypes (based on a minimum of 1000 inseminations) for 7000 AI bulls were used to identify bulls of high and low fertility. The most divergent bulls ($n=150$) were selected for targeted sequencing of β -defensin genes and an association study was performed to identify genetic regions significantly associated with male fertility. The most significantly associated single nucleotide polymorphisms (SNPs) were located in a haplotype consisting of 94 SNPs over 138kb, including the β -defensin 126 gene, found in bulls of high fertility. To examine the effect of the haplotype on BOEC binding, sperm from bulls with and without the β -defensin haplotype from both high and low fertility groups were compared. Briefly, BOEC were isolated from heifer oviducts, immediately post-mortem and seeded onto Merck Millipore EZ slides (Merck Millipore, Cork, Ireland) and cultured for seven days until a confluent monolayer was formed. Hoechst 33342-stained sperm from high fertility bulls with (H+ive; $n=3$) and without (H-ive; $n=3$) the haplotype as well low fertility bulls without (L-ive; $n=3$) were added to the cell monolayers for 30 min. Loosely bound sperm were gently washed away and the culture was then fixed with 2.5% glutaraldehyde. Sperm were observed under half-light/half fluorescence at 40X and the number of bound sperm was assessed by counting 10 random fields of view for each well. Data were analysed for normality of distribution, transformed where appropriate and analysed using analysis of variance in SPSS software. All results are presented as mean \pm s.e.m.**Results:** The mean adjusted pregnancy rate for the H+ive, H-ive and L-ive treatments was +4.3%, +5.4% and -6.7%, respectively. Preliminary results demonstrate no effect of the average number of sperm bound per field of view (4.9 ± 1.32 , 4.8 ± 1.47 and 4.8 ± 1.38 for the H+ive, H-ive and L-ive treatments, respectively). Sperm motility as assessed using computer assisted sperm analysis (CASA) was 55.3 ± 11.90 , 50.9 ± 10.52 and $38.2 \pm 4.49\%$, for the H+ive, H-ive and L-ive, respectively

($P > 0.05$). Similarly, there was no effect of treatment on any of the other post-thaw sperm motility or kinematic parameters assessed.

Conclusions: Our preliminary findings suggest that sperm from bulls of different β -defensin 126 haplotypes, and which differ in phenotypic fertility, do not differ in their post-thaw motility, kinematic or sperm binding properties. Fertility is a complex and multi factorial process and β -defensins may play a role in other aspects of fertility such as mucus penetration and fertilising ability.

Genetics and Breeding

P04-004-037

Economic values for production, functional and fertility traits in milk production systems in Southern Brazil

Heitor J. Cervo¹Júlio Otávio J. Barcellos¹Vanessa Peripolli²Concepta McManus²Eliana Pinheiro^{2*}

¹Animal Science, Federal University of Rio Grande do Sul, Porto Alegre, ²University of Brasilia, Brasilia, Brazil

Objectives: The objective of this study was to predict the economic values for production, functional and fertility traits, as well as to rank them in order of economic importance for milk production systems in southern Brazil.

Materials and Methods: On farm data were collected by technicians of the Brazilian Sebrae, through monthly monitoring of husbandry and economic data on 61 properties belonging to the microregion of Passo Fundo, southern Brazil, between 2009 and 2011. Two clusters were formed according to their production and the characteristics considered were: milk production (MP), lactation persistency (LP), milk fat (FAT), milk protein (PROT), somatic cell count (SCC), age at first calving (AFC), calving interval (CI), feed intake (Intake), mortality (MORT) and cow weight. The herd size was standardized to a 100-cow farm. The FACTOR procedure was used to understand the correlation structure and the sources of data variation. Analyses of variance were performed for economic and related milk production variables to differentiate between the clusters formed. Clusters 1 and 2 were designated high and medium-high output respectively, used for the economic values calculation. Revenue was based on the sale of milk, surplus heifers and cull cows and the actual operating costs were used to calculate profit and gross margin. The profit function used to calculate the economic values of traits related to milk quality was based on a 100-cow farm in three different scenarios (company that do not bonus/penalize for milk quality (I), which bonus or penalizes the lower range (II) and the higher range (III)). Sensitivity analyzes were performed to assess the impact of possible changes in the variations of dietary components in ± 25 and $\pm 50\%$ on the profit, when there is an increase of 1% in expression of the traits examined.

Results: The high production system (cluster 1) had higher production ($P < 0.10$) than the medium-high production system (cluster 2) as expected. Economically, higher income from the sale of milk (ISM) and the total income of dairy activity (TIDF) were seen, which resulted in higher gross margin (GM) for the high production system. High cluster had 22% higher annual income (sale of milk and animals) than the medium-high cluster. At the same time, the operating cost for production increased in smaller proportions (10%) determining higher gross margin (MB) (43%) and increased profitability (15%) compared to the medium cluster. Actual operating costs (AOC), between the two production systems showed that the higher cost was due to the animal feed (concentrate and roughage), with 75% of operating cost, for both

high and medium-high clusters and the second largest cost was due to the payment of labor, with an average of 12% of the operating cost. Considering the three scenarios, the average economic values of the characteristics that affect the profit of the producer for both clusters were in order: FAT: US \$ 3,776.07; PROT: US \$ 1,888.03; MP US \$ 1,258.69, LP: US \$ 1,258.69; Weight: US \$ 124.03; MORT: US \$ -14.30; INTAKE: US \$ -614.01; CI: US \$ -1,023.62; AFC: US \$ -2,724.29; SCC: US \$ -3,146.87. The decrease in the diet costs caused an increase in the profit percentage. On the other hand, the increase (+25 and +50%) in diet costs, would cause a decrease in farm profits (up to 25% in AFC with 50% increase in diet costs).

Conclusions: The economic values calculated for the characteristics related to volume of milk, fertility, milk quality, disease resistance, feed intake and mortality used in breeding programs resulted in increased profitability for milk production traits and weight for any scenario (I, II and III); increased profitability for milk quality characteristics for scenario II and III and decreased in profitability for fertility traits, consumption and mortality for scenarios I, II and III, and for characteristic related to the milk quality in scenarios II and III.

Genetics and Breeding

P04-004-038

Non-genetic factors affecting somatic cell count, milk urea content, test-day milk yield and milk protein percent in dairy cattle

Elsaid Z.M. Oudah^{1*}

¹Department of Animal Production, Faculty of Agriculture, Mansoura University, Mansoura, PC 35516, Egypt

Objectives: This study had two aims. Firstly, to determine the associations of month of recording (MOR) and days in milk (DIM) with somatic cell count (SCC), milk urea concentration (MU) and milk production traits (i.e. test-day milk yield, TDM; milk protein percentage, PP and milk protein yield, PY). Secondly, to evaluate the associations among SCC, MU and milk production traits by analyzing individual monthly test-day records for dairy cows raised in the Czech part of the Czech Republic.

Materials and Methods: A total number of 33,881 individual test-day milk records involving 15,565 dairy cows for a 12-month period enrolled in Database Computer Center belonging to Czech Moravian Breeders' Corporation, Inc., Hradistko, the Czech Republic was used. Individual test-day milk samples were analyzed in the Milk Testing Laboratory of Buřtehrad. Somatic cell count was estimated using Bentley Instruments (Somacount 3000, the instrument utilize a laser based flow cytometry). Protein percentage was estimated also using Bentley Instruments (Bentley 2000, infrared transmission photometer). The direct specific enzymatic method UREAQVANT (made by Agroslužby Morava a Slezko) was used for the routine determination of the MU. Data analysis was performed using the Statistical Analysis System (SAS/STAT 9.1 User's Guide, 2004). To control the repeated measures on different test-day record at the same cow level, repeated measures statements were used in the statistical analyses. In order to allow the inclusion of repeated measures statements in the statistical model, a minimum of two dependent variables per statistical model was imposed for the statistical analysis by SAS (2004). Descriptive statistics (i.e. mean, SD, CV %, minimum, and maximum) were also computed for TDM, PP, PY, SCC, SCS, MU and DIM using SAS (SAS, 2004). Summary of the descriptive statistics of test-day records.

Results: Analysis of variance shows that MOR and DIM has highly significant ($P < 0.01$ or 0.001) effects on all studied traits. The coefficient of determination (R^2) varied from 4% (for SCC) to 84% (for PY). In general, the magnitude of the effect of these factors including in the models in SCC, SCS and MUN was small. Only 4.0, 7.0 and 18.0% of the variation in SCC, SCS and MU values, respectively were explained by the factors studied. It is clear that there are other sources that account for most of the variation in SCC and MUN (including nutritional factors) which were not included in this study. Coefficient of variation (CV %) varied from 8.92% (for PP) to 183.8% (for SCC). The R^2 varied from 41% to 69% for the studied traits, with SCS having the lowest R^2 coefficients in all three lactations. Very high standard deviation for SCC was reported also by Ng-Kwai-Hang et al (1985) who found that SCC in terms of thousands per milliliter of milk was the most variable component with an overall mean of 297 and a standard deviation of more than twice this. The R^2 for the GLM procedure that examined the relationship between the variables and MU was 0.47 using a large database ($n = 1,279,600$). The differences in the values of R^2 and CV% may be due to the different statistical analysis, breed, number of observations and/or fixed effects included in the statistical model. A negative linear relationship between milk yield and PP in the same milking was observed. TDM for PP less than 3.2% was 24.6 kg, meanwhile, it was 18.6 kg for PP > 3.8 .

Conclusions: Highly significant effects ($P < 0.001$) on SCC, MU and milk production traits were found for MOR and DIM. Therefore, the effects of environmental variables must be taken into consideration when cows are evaluated and when developing and comparing models to be used in adjusting data to provide the best estimates of genetic parameters for selection purposes in the dairy cattle evaluation. The results demonstrate the importance of surroundings and management practice. Therefore, management play a great role as source of variability and has a effective role in maintaining optimum SCC and MU levels for health status and nutrition.

Identification Of Snps In Fcgrt Gene And Their Association With Gamma Immunoglobulin Concentrations In Buffalo (*Bubalus bubalis*)

Swati Agrawal¹Subodh Kumar¹Rajni Chaudhary¹Yathish H.M.¹Nihar R. Sahoo¹

¹Division of Animal Genetics, Indian Veterinary Research Institute, Izatnagar, India

Objectives: Calf mortality causes a major economic loss to dairy production. In ruminants, a calf is born agammaglobulinemic because transfer of antibodies through syndesmochorial placenta does not occur. The neonate is completely dependent on the absorption of maternal antibodies from colostrum as a source of immunity against diseases which occurs non-selectively by pinocytosis facilitated by certain receptors of small intestine known as neonatal Fc receptors (FcRn). This is encoded by B2M and FCGRT gene. We attempted to detect SNP's in FCGRT gene in buffalo and ascertain their association with IgG concentration in dams' colostrum and calves' serum.

Materials and Methods: Indirect ELISA was performed to determine the Immunoglobulin-G (IgG) concentration in serum samples of eighty murrah buffalo calves born during August 2013 to February 2015 and colostrum of their respective dams. The dams and calves were separately ranked in ascending order of colostrum and serum IgG concentration, respectively. Animals (dams or calves) which fell in bottom one quarter and best one

quarter were subjected to DNA isolation and subsequent experimentation. Nine pairs of primers (three pairs for the last exon) were designed to amplify nine fragments corresponding to seven exons of FCGRT gene in buffalo. SNPs were identified by PCR-SSCP of nine fragments. The odds ratio was calculated to ascertain the SNPs that were significantly associated with IgG concentration either in colostrum or serum.

Results: The mean value of IgG in low and high yielder dams was 32.25 ± 1.76 and 70.33 ± 5.28 respectively. Similarly, the mean value of serum IgG in low and high yielder calves was 2.85 ± 0.34 and 16.51 ± 0.47 , respectively. The PCR SSCP analysis and sequencing of fragment 2 (342 bp) revealed three G288C, C302T and C122G SNPs. The PCR SSCP analysis and sequencing of fragment 3 (372 bp) revealed three alleles A, B and C that differed at nucleotide positions 40 and 332. Analysis and sequencing of fragment 4 (361 bp) revealed three patterns A, B and C and two SNPs viz. A75G transition in exon 4 and G314T transversion in intron 4. Polymorphism at 75th position (A to G) lead to sense mutation so change of amino acid from isoleucine (I) to valine (V). The PCR SSCP analysis and sequencing of fragment 7A (339 bp) revealed two alleles A and B that differed at nucleotide positions 139 and 270. The PCR SSCP analysis and sequencing of fragment 1 (308 bp), fragment 5 (392 bp), fragment 6 (250 bp), fragment 7B (330 bp) and fragment 7C (157 bp) did not reveal any SNP hence these fragments were observed as monomorphic. In calves, for the SNP G40T in fragment 3, the presence of G and T allele at 40th position was significantly ($P \leq 0.05$) differing in low IgG and high IgG groups. In dams, both the SNPs (A75G and G314T) in fragment 4, were found to differ significantly ($P \leq 0.05$) in low IgG and high IgG groups. In dams, in polymorphic fragment 4, the haplotypes (AG, AT and GT) were found to differ significantly ($P \leq 0.05$) in low IgG and high IgG groups.

Conclusions: We identified 9 SNPs, located in different exonic and intronic regions of FCGRT gene in murrah breed of buffaloes. Seven SNPs were located in intronic (non coding) regions while 2 SNPs corresponded to exonic (coding) regions, one being nonsynonymous, causing alteration of Isoleucine (Ile) to valine (Val) while the other being synonymous mutation. Both the SNPs (A75G and G314T) present in fragment 4 in dams exhibited a significant bearing on colostrum IgG. Similarly the SNP (G40T) present in fragment 3 in calves exhibited a significant bearing on serum IgG.

Genetics and Breeding

Influence Of Mirna On Proliferation And Differentiation Of Bovine Satellite Cells On Different Stages Of In Vitro Myogenesis

Tomasz Sadkowski¹Anna Ciecierska¹Jolanta Oprządek²

¹Department of Physiological Sciences, Warsaw University of Life Sciences - SGGW, Warsaw, ²Department of Animal Improvement, Institute of Genetics and Animal Breeding of the Polish Academy of Sciences, Jastrzębiec, Poland

Objectives: The goal was to identify the role of miRNAs in skeletal muscle development in cattle breeds of different performance in order to understand the molecular mechanisms of myogenesis influencing beef gains and quality.

Materials and Methods: Samples of semitendinosus muscle were collected from 15 months-old bulls of beef (Hereford, HER & Limousine, LIM) and dairy (Holstein-Friesian, HF) breeds. Muscle samples were cleaned of other tissues, sliced and suspended in sterile

FBS with 10% addition of DMSO and then gradually cooled down to -80°C. Satellite cells were isolated according to the modified protocol of Baquero-Perez et al. (2012). Subsequently, cells were cultured in proliferation medium (10%FBS/DMEM/antibiotics). After reaching 80% of confluence cells were collected for further analysis (control condition) or proliferation medium was replaced by differentiation medium (2%HS/DMEM/antibiotics). After the 2nd and 6th day of differentiation cells were scraped and stored at -80°C until further analysis. Microarray analysis was performed using Bovine Custom miRNA Microarray 8x60K AMADID, (Agilent Technologies, USA). The total RNA from proliferating and differentiating cell samples was isolated using miRNeasy Mini Kit (Qiagen, USA) labelled and hybridized to microarray slides. The microarray output text files were analyzed using GeneSpring 13 (Agilent Technologies, USA). ANOVA with $p \leq 0.05$, $FDR \leq 0.05$ and fold-change of at least 2.0 were used as the criteria of significance. To validate microarray data, Real-time RT-PCR analyses were performed. For this purpose miRCURY LNA First-strand cDNA Kit, miRCURY LNA SYBR Green master mix and miRNA primers (Exiqon, USA) were used. Statistical analyses were done using GenEx 6 (MultiD, Sweden). Ontological analysis was performed using PathwayStudio 11 (Elsevier, Holland).

Results: The analysis of miRNA expression was performed in bovine satellite cells (BSC) at early and late stages of differentiation (2nd and 6th day) as well as in proliferating cells (80% confluence) used as a control. Microarrays were performed separately for each breed (HF, HER, and LIM). For Limousin, 44 miRNAs showed differential expression in differentiating (day 2 and 6) vs. proliferating cells. Similar analysis for the BSC derived from Hereford bulls allowed identification of 34 differentially expressed miRNAs. In the case of Holstein-Friesian bulls 39 miRNAs were identified. Global analysis of the miRNA expression in the aforementioned conditions showed a group of 13 miRNAs manifesting similar expression trends on 2nd and 6th day of differentiation in all examined breeds. Ontological analysis of identified miRNAs has revealed that they take part in the following biological processes: myoblast proliferation, myoblast differentiation, satellite cell activation and myogenesis. Additionally, the three miRNAs, whose expression was similar for beef but different from dairy bulls, were identified in both analyzed conditions (2nd day of differentiation vs. proliferation and 6th day of differentiation vs. proliferation). The cluster analysis showed that the expression of miRNAs in BSC from beef bulls shows a greater similarity between 2nd and 6th day of differentiation while expression of miRNAs in BSC of dairy breed has a greater similarity between the proliferating cells and cells entering differentiation (2nd day).

Conclusions: It seems that the identified group of 13 miRNAs could be classified as common regulators of myogenesis in cattle, since they change their expression during various steps of differentiation in a similar manner in all examined breeds. The identified 3 miRNAs (miR-133b, miR-206 and miR-2487) specific for HER & LIM may be the main regulators of myogenesis in beef breeds responsible for rapid and more intensive growth of myotubes observed *in vitro* and the enhanced muscle mass gains *in vivo*. Furthermore, cluster analysis has shown possible higher miRNA-related differentiation potential of BSC isolated from muscle tissue of beef breed bulls.

Genome-wide association study of immunoglobulin absorption in neonatal Holstein calves

Derek Foster¹ Steven Friedenber² Kathryn Meurs²

¹Population Health and Pathobiology, ²Clinical Sciences, NC State University College of Veterinary Medicine, Raleigh, United States

Objectives: Absorption of colostral immunoglobulins in neonatal calves is critical to health early in life, but appears to be vary widely between calves. The objective of this study was to identify single nucleotide polymorphisms (SNPs) associated with the efficiency of absorption of colostral immunoglobulins in neonatal Holstein calves.

Materials and Methods: 102 Holstein heifer calves born without assistance on 3 farms were enrolled in the study. Blood samples were collected between 24 and 36 hours of age. Whole blood was stored for genetic analysis, and serum was stored for IgG quantification. Samples of colostrum fed to each calf were also stored for IgG quantification. IgG concentration in the colostrum and serum samples was measured by radial immunodiffusion assay, and apparent efficiency of absorption (AEA) was calculated for each calf. A genome-wide association study was performed using the Illumina Bovine HD array (over 777,000 SNPs) to identify SNPs associated with AEA in which AEA was treated as a quantitative trait.

Results: AEA ranged from 7.7% to 59.9%. The mean AEA in the calves was 28.1%. After correction for population stratification using Efficient Mixed-Model Associated Expedited (EMMAX), SNPs on chromosome 2 ($p_{raw} = 1 \times 10^{-7}$) and chromosome 13 ($p_{raw} = 1.3 \times 10^{-6}$) were found to be associated with improved efficiency of absorption of IgG. These SNPs associated with improved AEA were found in 4 and 5 calves, respectively. Multiple candidate genes were found in these areas. No SNPs were associated with a decreased AEA.

Conclusions: There is wide variation in the efficiency of IgG absorption in Holstein calves. Further characterization of sequence variation in these two regions may provide an economical means to select for cattle with improved efficiency of absorption, allowing for reduced rates of failure of transfer of passive immunity.

Analysis of the genetic population structure of the Crioula Lageana cattle breed

Tomaz G. Pezzini¹ Edison Martins² Arthur D. S. Mariante³ Samuel R. Paiva³ José L. Jivago⁴ Vanessa Peripolli⁴ Concepta McManus⁴

¹Ministry of Agriculture Livestock and Food Supply, Brasilia, ²Brazilian Association of Cattle Breeders of Creole Lageana Breed, Lages, ³Embrapa Genetic Resources and Biotechnology, ⁴University of Brasilia, Brasilia, Brazil

Objectives: Knowledge of the population structure of Crioula Lageana breed is essential to provide the foundation for understanding the evolution of genetic parameters of this population, assisting in improving conservation programs and sustainable use this genetic resource. Thus this study aims to characterize the population structure of locally adapted Crioula Lageana Brazilian cattle breed to assess genetic diversity.

Materials and Methods: Data from 1,638 animals from Santa Catarina Plateau from the database of the Brazilian Association of Crioula Lageana Cattle Breeders (ABCCL), collected over a 38 year period were used. Information included the registration number, date of birth, sex, dam and sire registration number, and farm. Data analysis of the genetic structure of bovine breed population Crioula Lageana was performed using the program ENDOG v.4.6, and the following parameters were calculated: pedigree integrity index (PI), inbreeding coefficient (F), inbreeding rate (Δf), effective population size (Ne), average relationship coefficient (AR), effective founders (fe), effective ancestors (fa), genetic conservation index (GCI), generation interval (GI) and Wright's F statistics.

Results: Pedigree information is in the fifth generation, and only 44.87% of the animals had a known sire, while 40.42% have a known dam. Effective population size (Ne) ranged from 72.53 in complete generations to 143.90 in maximum generations, which is above the minimum value considered by the Food and Agriculture Organization of the United Nations to guarantee maintenance of maximum genetic variability. Inbreeding (F) and Average Relatedness (AR) were 0.34% and 0.91%, respectively. The effective number of founders (fe) and ancestors (fa) in this study were 29 and 28 animals, respectively, and only ten ancestors were responsible for 50% of the genetic variability of the whole population. The average generation interval was 5.84 years in the paternal line and 7.70 in the maternal line. Wright's F statistics indicate low genetic distances between subsets in relation to the total population ($F_{st}=0.0015$), between individuals with respect to their subpopulation ($F_{is}=-0.0027$) and between individuals in relation to the total population ($F_{it}=-0.0012$). This indicates a low genetic differentiation in the population studied. Analysis of population genetic structure of Crioula Lageana cattle indicates that, despite the small number of animals with known parentage and considerable loss of genetic variability by the constant use of a few sires, the population showed good genetic management, low inbreeding, low genetic differentiation among subpopulations and adequate effective population size for breed preservation.

Conclusions: The analysis of the genetic structure of the Crioula Lageana cattle breed population indicates a reduced number of known animal pedigree and considerable loss of genetic variability for the development of a population with a narrow genetic base. The population has low levels of inbreeding, low genetic differentiation among subpopulations and an effective population size above the recommended by FAO to maintain maximum genetic variability over the generations.

Population viability analysis of the Crioula Lageano cattle

Tomaz G. Pezzini¹ Edison Martins² Arthur D. S. Mariante³ Sanuel R. Paiva³ José L. Jivago⁴ Vanessa Peripolli⁴ Concepta McManus⁴

¹Ministry of Agriculture Livestock and Food Supply, Brasília, ²Brazilian Association of Cattle Breeders of Creole Lageana Breed, Lages, ³Embrapa Genetic Resources and Biotechnology, ⁴University of Brasília, Brasília, Brazil

Objectives: The objective of this study was to perform a population viability analysis with the locally adapted Crioula Lageana Brazilian cattle breed of cattle to study its demographic and genetic parameters, as well as verify the interference of factors that may affect the survival and development this population over a 500-year timespan.

Materials and Methods: The interaction between demographic, environmental and genetic factors on the population of Crioula Lageana animals was evaluated using the VORTEX software. There were 128 simulated hypothetical scenarios. The input variables in the program were as follows: initial population consisting of 1,408 animals, with 205 males and 1,203 females (current population); 100 repetitions performed in each scenario; 100 and 500 years simulation time; land capacity (K) of 500 animals; no removal of animals and removal of 100 animals from the population annually; sexual maturity at 2 years of age and maximum reproductive age of 15 years; one offspring per pregnancy with 50% of likelihood of being born male and female; 5:95; 15:85; 30:70 and 50:50 ratio of males to females in a population of 100 animals intended for breeding annually; inbreeding depression with a lethal amount of 3.14 equivalents per diploid genome; 5, 10, 25 and 40% of mortality at the first year of life and 2.5% over one year of age as well as five catastrophic events one every 20 years for the scenarios with up to 100 years, and a catastrophic event every 100 years for the scenarios up to 500 years. Using demographic, genetic and stochastic information of the Crioula Lageana breed the expected heterozygosity (He) and inbreeding coefficient (F), the deterministic growth rate (det.r), the population size, the probability of extinction as well as the population dynamics parameters were calculated.

Results: The possibility of extinction of Crioula Lageana breed over the next 500 years was remote, even in less favorable scenarios. The deterministic growth rate (det.r) was always positive during the evaluated period, and the mortality of animals up to one year of age was the most important factor that affected this parameter. The population size increased rapidly until the carrying capacity (k) was reached, which was a limiting factor for population growth. The level of retained heterozygosity (He) in the population in the worst scenario was above 80% and the coefficient of inbreeding (F) was always below 0.20 at the end of the 500 years of simulation.

Conclusions: The assessment of population viability of Crioula Lageana the Santa Catarina Plateau breed showed that this population has no apparent long-term risk of extinction as a result of its high genetic diversity and adequate demographic structure, and the area's carrying capacity is the main limiting factor for population growth. Farmers should adopt measures to ensure a low mortality rate in the first year, and a high male:female ratio.

Determination Of Haplotypes In Beta-2 Microglobulin Gene And Their Effect On Immunoglobulin-G Levels In Buffaloes

Rajni Chaudhary¹ Subodh Kumar^{1*} A. Sivakumar¹ Chinmoy Mishra¹ Anuj Chauhan¹ B. Sivamani²

¹Division of Animal Genetics, Indian Veterinary Research Institute, Izatnagar, ²Div of Nutrition, Genetics and Biotechnology, CIBA, Chennai, India

Objectives: Neonatal calf mortality is one of the major causes of economic losses in livestock production particularly in buffaloes. The new-born calves carry no antibodies in their blood stream at birth due to the uterine barrier. Therefore their only source of gaining immunity is through passive transfer of immunoglobulins. The passive transfer of immunity is determined by the neonatal receptor i.e. FcRn, which is a heterodimer composed of two subunits viz. FCGRT and Beta 2

microglobulin. We resorted to explore polymorphism/haplotypes in β_2 -microglobulin (β_2M) and ascertain their effect on IgG levels in dams' colostrum and calves' serum.

Materials and Methods: The β_2M gene in buffaloes was amplified in forty newly parturated murreh buffaloes and their respective new born calves by employing seven pairs of primers for amplification of both exonic and intronic regions i.e., fragment I (206 bp: full exon 1), fragment II (296 bp: partial intron 1), fragment III (287 bp: full exon 2), fragment IV (227 bp: partial intron 2 and full exon 3), fragment V (226 bp: partial intron 3), fragment VI (201 bp: initial partial exon 4) and fragment VII (405 bp: remaining partial exon 4) in the DNA samples of Murreh buffaloes which were designed on the basis of sequences of cattle (*Bos taurus*) in public database at NCBI (AC_000167.1). Genomic DNA was extracted from 5 ml of venous blood. The quality, purity and concentration of DNA was checked. The reaction mixture and PCR programme were optimized to achieve the satisfactory level of amplification for all the seven fragments. Polymerase chain reaction- single stranded conformational polymorphism (PCR-SSCP) technique was used to explore the polymorphism in β_2M gene of Murreh buffaloes. The different banding patterns were identified and each representative pattern was sequenced. The haplotypes in dams and calves were determined. Indirect ELISA was done to estimate IgG concentrations in colostrum (first milking) whey and serum of new born calves (6 to 12 hrs post birth). The effect of different haplotypes was evaluated on IgG concentrations by using PROC GLM module of SAS9.3 software.

Results: The PCR-SSCP analysis and sequencing of different patterns of fragment I revealed two genotypes AA and BB with only one SNP viz. C45G in 5'UTR. The analysis and sequencing of fragment II revealed two genotypes AA and BB due to SNPs viz. T22A, T23A and G256A in intron 1. The analysis and sequencing of different patterns of fragment III revealed only one SNP viz. T204C in exon 2. The genotypic frequencies of AA and BB genotypes were 95 and 5 % respectively. Polymorphism at 204th position (T to C) did not lead to alteration of amino acid hence was a synonymous (silent) mutation. The PCR-SSCP analysis and sequencing of PCR products of fragment IV, V and VI did not revealed any SNP hence, exon 3, intron 3 and exon 4 of β_2M gene were observed as monomorphic. The PCR-SSCP analysis and sequencing of different patterns of fragment VII revealed four SNPs viz. G80A, A101C, A208G and A239G in fourth exonic region (3' UTR). The patterns were designated as AA, BB, CC and DD genotypes whose overall genotypic frequencies were 47.5, 30, 15 and 7.5 % respectively. The identified 9 SNPs resulted in 7 different haplotypes in buffalo dams and 14 different haplotypes in calves. The mean IgG concentration in dams' colostrum and calves' serum were 51.71 ± 5.99 and 11.68 ± 0.75 mg/ml respectively. The effect of different haplotypes was evaluated on IgG concentrations. The least square analysis of variance revealed a non-significant effect of dam haplotype on colostrum IgG concentrations as well as calf haplotype on serum IgG concentrations.

Conclusions: Nine SNPs were identified in seven amplified intronic and exonic regions of the β_2M gene. Out of these SNPs eight SNPs lied in non coding region while one SNP lied in coding region (T204C in exon 2). This nucleotide change was synonymous type i.e., no change in amino acid occurred due to this SNP. These SNPs resulted in 7 haplotypes in dams and 14 haplotypes in calves. ANOVA did not reveal any significant effect of haplotype on IgG concentrations (either dam or calf).

Evaluation of morphometric data of Criollo Lageano cattle

Tomaz G. Pezzini¹ Edison Martins² Arthur D. S. Mariante³ José L. Jivago⁴ Vanessa Peripolli⁴ Concepta McManus⁴

¹Ministry of Agriculture Livestock and Food Supply, Brasilia, ²Brazilian Association of Cattle Breeders of Creole Lageana Breed, Lages, ³Embrapa Genetic Resources and Biotechnology, ⁴University of Brasilia, Brasilia, Brazil

Objectives: The objective of this study was to evaluate the body measurements of the cattle breed Creole Lageana at different ages in the three regions of Santa Catarina plateau, in order to establish the patterns of variation of these measures, contributing to the phenotypic characterization of the breed.

Materials and Methods: Body measurements were collected from 346 animals from three different regions (Coxilha Rica, Campos de Caçador and Campos de Curitiba) of the Plateau of Santa Catarina State. The following measurements were taken: body length, height at withers, thoracic girth, rump height, rump width and rump length. The morphometric measurements were evaluated in terms of age, gender and region of origin. The statistics analysis included an analyses of variance, correlation, principal factors, as well as cluster, discriminant and canonical analyses.

Results: All measurements, except for rump height, showed a statistical difference between males and females, demonstrating the sexual dimorphism present in this breed. In relation to age, it was observed that rump height varied until animals between 3 and 5 years of age; while rump width and thoracic girth varied until animals between 7 and 9 years. Height at withers and rump length stabilized in animals between 9 and 11 years, and the last trait to stabilize was body length, which only stop growing in animals above 11 years of age. The cluster analysis, based on morphometric information of this breed, showed a small distance between animals from the region of Campos de Curitiba when compared to animals from the regions of Coxilha Rica and Campos de Caçador. The discriminant analysis identified that an increase in body length, height at withers and rump length were associated with a decrease in rump height and rump width. The linear measurements that presented the greatest correlation were thoracic girth, rump width and rump length, with values above 0.80.

Conclusions: The analysis of body measurements indicated that the Criollo Lageano cattle breed show sexual dimorphism, low differentiation between regions in the Plateau of Santa Catarina State and late finishing, suggesting that farmers do not select the animals for early termination, but that they should join forces for the inclusion of this breed in added value production systems such as certification of Protected Designation of Origin of its meat.

Performance and carcass traits in locally adapted Brazilian cattle

Vanessa Peripolli¹ Candice B. Tanure¹ Luiza Seixas¹ Gustavo L. Costa² Marcos F. Costa³ Maria Clorinda S. Fioravanti² João Restle² Andrea A. Egito⁴ Concepta M. McManus¹

¹University of Brasilia, Brasilia, ²Federal University of Goias, ³Embrapa Rice and Bean, Goiania, ⁴Embrapa Beef Cattle, Campo Grande, Brazil

Objectives: The objective of the present study was to compare quantitative and qualitative carcass characteristics of Pantaneiro, Curraleiro Pe Duro and Nelore Brazilian cattle breeds under commercial feedlot conditions.

Materials and Methods: Fifteen males, approximately two years of age, of Pantaneiro, Curraleiro Pe-duro and Nelore breeds were evaluated after 17 days of adaptation for 97 days. The animals were reared as one group with the same environmental and treatment conditions and fed with 70% roughage, 30% concentrate, mineral salt and water ad libitum. Animals were weighed after 14 hours of fasting at the beginning and the end of the experimental period. The eye muscle area and fat thickness on the eye muscle area were determined in the cross section of the 12th and 13th ribs from the left half carcass in Longissimus lumborum, using ultrasound (Aloka SSD-500) at the beginning and end of the experimental period. Animals were slaughtered on three dates, with one third of each genetic group per day and the conformation (CF) and physiological maturity (FM) of the carcasses were evaluated. Carcass length (CL), leg length (LL), arm length (AL), thigh thickness (TT), and arm circumference (AC) were recorded using a measuring tape. Sirloin was analyzed for meat color using a colorimeter (Konica Minolta®) to evaluate the brightness (L^* 0 = black, 100 = white), the intensity of the red color (a^*) and the intensity of the yellow color (b^*). The statistical analysis included an analyses of variance, correlations, principal factors, as well as discriminant and canonical analyses.

Results: Nelore animals had the highest initial and final weight, physiological maturity and leg length (346.8 kg; 475.46 kg; 14.11; 74.54 cm, respectively). The initial weight of the animals had a significant effect on conformation, carcass length, arm circumference and thigh thickness, however arm length showed no effect. For the qualitative carcass characteristics of sirloin, the Nelore breed presented more brightness and intensity of red color compared to the other breeds, however, the yellow color was not different between breeds.

Conclusions: The Nelore Brazilian cattle breed presented the best carcass quantitative and qualitative characteristics when compared with Pantaneiro, Curraleiro Pé Duro breeds, under commercial feedlot conditions.

Herd Health Management: Beef

P01-001-017

Prevalence and risk factors of injection site lesions in UK beef cattle

Liz Cresswell ¹John Remnant ¹Andy Butterworth ²Wendela Wapenaar ^{1*}

¹University of Nottingham, Sutton Bonington, ²University of Bristol, Bristol, United Kingdom

Objectives: Injectable veterinary medicines are widely used in cattle, and in particular vaccines are used on large numbers of animals in the herd. The formation of injection site lesions (ISLs) is a risk when using injectable products, and has potential consequences for meat quality, animal welfare and beef industry revenue.

Materials and Methods: This study collected carcass observation data in abattoirs to determine ISL prevalence in UK beef animals, which was linked with a questionnaire investigating cattle vaccination techniques amongst UK beef farmers.

Carcasses were inspected visually by Food Standards Agency and slaughterhouse staff at both control points and any lesions or abnormal tissue was removed from the carcass. The tissue was labelled with the date and kill number. Where possible a gross morphological description was recorded.

A questionnaire was developed and distributed in paper format and online to cattle farmers in the UK between September and November 2011 using a convenience sample. The questionnaire contained 23 questions about cattle vaccine uptake, and collected data on how the vaccines were stored and administered.

Results: There was a trend (p=0.22) towards a difference in distribution between site of vaccine administration (60% in neck, 33% in rump) and site of lesions observed at the abattoir (42% in neck, 47% in rump)

When asked 'When administering this vaccine by injection (using e.g. a syringe, vaccinator gun), which of the following apply on your farm?' 43% of respondents started each vaccination session with a new needle or changed needles when they became broken or blunt.

The ISL prevalence was 4.1%, and the difference between sites being used for vaccination and the distribution of ISLs on carcasses suggested that factors other than vaccination were contributing to ISL incidence. Questionnaire responses highlighted deficits in compliance such as site of injection and correct needle usage.

Conclusions: The role of the veterinary surgeon in knowledge transfer is crucial in providing practical injection advice when prescribing vaccines and other veterinary medicines. This presentation will highlight practical factors that can be addressed by veterinary surgeons to reduce ISL formation in beef animals.

Herd Health Management: Beef

P01-001-019

On-farm mortality and related risk factors for Estonian beef cattle

Kerli Mõtus ^{1*}Kaari Reimus ¹Toomas Orro ¹Arvo Viltrop ¹

¹Institute of Veterinary Medicine and Animal Sciences, Estonian University of Life Sciences, Tartu, Estonia

Objectives: On-farm cattle mortality (euthanasia and termination) is involuntary loss of an animal associated with economic consequences to the farmer. High on-farm mortality is one of several indicators of suboptimal animal health and welfare. So far, scarce information about mortality and related risk factors exist in beef cattle population. Objective of this study was to assess beef cattle mortality in Estonian beef herds and discover potential risk factors associated with mortality.

Materials and Methods: Animal level data of all cattle in Estonian beef herds (consisting of more than 75% of beef cattle) was extracted from the Estonian Agricultural Registers and Information Board database for the years 2013 and 2014. Study population consisted of 58,708 cattle from 1,186 herds and 69,413 animals from 1,288 herds for years 2013 and 2014, respectively. The associations between possible risk factors (age, breed, gender, herd size, region) and mortality was analysed with Weibull proportional hazards models with farm as random effect. Interaction terms were introduced as separate variables in the model. Statistical analyses were performed with Stata MP version 14 (StataCorp LP, College Station, USA).

Results: Among 48,918 animal-years 1,166 animals died or were euthanized with resultant mortality risk of 1.99% and mortality rate of 2.38 per 100 animal-years in 2013. In 2014 1,030 deaths and euthanasias occurred per 57,602 animal-years resulting in a mortality risk of 1.48% and 1.79 per 100 animal-years. Significant decline in cattle mortality within two years could be identified (p < 0.001). According to multivariable Weibull proportional hazard random effect model the mortality risk was highest among male cattle up to one years old (HR = 1.20, 95% CI 1.05; 1.37) followed with females in the same age group (the baseline group). The hazard of dying declined with increasing age. In general, male cattle from older age groups (>12 months) experienced lower risk of mortality compared to females. An increased mortality of cattle from 'other' breed group consisting animals from breeds underrepresented in the Estonian beef herd's was established (HR = 1.37, 95% CI 1.13; 1.66, p = 0.002) compared to Aberdeen Angus, which was the baseline group in the model. The effect of herd size was dependent on the region. Mortality risk was highest among animals in largest herds (≥75 cows) from South of Estonia (HR = 2.11, 95% CI 1.52; 2.95, p < 0.001) followed with those kept in herds with 50-75 cattle in the same region (HR = 1.94, 95% CI 1.38; 2.73, p < 0.001) compared with baseline group (smallest herds with <10 cows in South of Estonia).

Conclusions: Results of our study demonstrate on-farm mortality rate comparable with other studies and declining between years 2013 and 2014. This study revealed several factors influencing beef cattle mortality in Estonia. More research is needed in order to advise beef cattle farmers in their decisions when reducing on-farm mortality.

Herd Health Management: Beef

P01-001-020

Evaluation of on-arrival vaccination and deworming on stocker cattle health and growth performance

Courtney M. Griffin ¹Brandi Karisch ²Amelia R. Woolums ¹John Blanton ²Ray M. Kaplan ³William Epperson ¹David Smith ^{1*}

¹Pathobiology and Population Medicine, ²Animal and Dairy Science, Mississippi State University, Mississippi State, MS, ³Infectious Diseases, University of Georgia, Athens, GA, United States

Objectives: The effect of vaccinating beef calves arriving to a pasture-based growing (stocker calf) system is poorly documented and potentially detrimental because the immune system of stressed calves

may not be able to efficiently process additional antigens. In the short-term, deworming cattle may not overcome the detrimental effects of parasitism at arrival. Our objective was to evaluate the effect of on-arrival vaccination and deworming on bovine respiratory disease (BRD) incidence, mortality, and growth of stocker calves in the southeastern United States.

Materials and Methods: Calves (n=80) received from an order-buyer through typical auction market systems were stratified by d-3 weight and fecal egg count into 20 pens of 4 animals each. Pens were randomly assigned to treatments in a 2x2 factorial design to test vaccination at arrival (d0 modified-live BHV-1/PI3V/BVDV1/BVDV2/BRSV and clostridial vaccine or not) and deworming (d0 oral fenbendazole and levamisole or not). Body weight and blood was collected days 0, 14, 28, 42, 56, 70 and 85. Fecal egg counts were measured days -3, 28, 56, and 85. Clinical signs of BRD (depression, anorexia, rapid respiratory rate, cough, nasal discharge, and rectal temperature of ≥ 40 C) were monitored daily. Treatment effects on BRD incidence, mortality, and growth were tested using Poisson, logistic, or linear regression, respectively ($\alpha \leq 0.05$).

Results: BRD incidence was greater for calves with d0 vaccination (RR=3.2), high (≥ 40 C) fever at day 0 (RR=6) and higher d-3 FEC (RR=1.2 per 100 epg). Mortality was greater for d0 vaccination (OR=8.3) and high fever (OR=41.6). Growth was lower for d0 vaccination (-4.7 kg), moderate (39.4-39.9 C) and high fever (-10.9 kg and -7.3 kg, respectively), and number of times treated for BRD (-7.9 kg/treatment). Deworming at arrival was not found to be significantly associated with BRD morbidity, mortality, or weight gain.

Conclusions: Health and growth performance of stocker calves may sometimes be adversely affected by vaccination at arrival. Deworming stocker calves at arrival may not always be beneficial to health or performance in the first 85 days after arrival. Degree of parasitism, as evidenced by fecal egg count, and presence of fever at arrival may be important predictors of subsequent BRD diagnosis. Both of these factors may also be important confounding variables to control for during design or analysis of BRD studies.

The participation of the bovine respiratory disease complex on the mortality and morbidity rates in a feedlot from southeastern Brazil

Anderson L. Baptista¹ Amanda L. Rezende¹ Pedro A. Fonseca¹ Geison M. Nogueira¹ Ronaldo L. Moura¹ Selwyn A. Headley² Guilherme L. Menezes¹ Amauri A. Alfieri² João Saut^{1*}

¹Large Animal Health Laboratory, Faculty of Veterinary Medicine, Universidade Federal de Uberlândia, Uberlândia, ²Department of Veterinary Preventive Medicine, Universidade Estadual de Londrina, Londrina, Brazil

Objectives: This study investigated the contribution of bovine respiratory disease (BRD) towards the development of morbidity and mortality in a beef cattle feedlot located in southeastern Brazil during a two-year-period (2013-2014).

Materials and Methods: All steers with clinical manifestation of disease were immediately separated from the particular pen and examined by the on-site veterinarian. Data relative to clinical diagnoses, therapy, morbidity, and mortality were tabulated daily into a Microsoft Excel spreadsheet. This information was used as input data for the results of this study. The evaluation used for the characterization of respiratory disease was based on the DART system (Zoetis, Florham Park, NJ) with modifications from Wilson et al. (2015). Clinical diagnoses were classified into seven large predetermined groups: BRD, feed refusal, clostridial diseases, lameness, bloat, trauma, and polioencephalomalacia (PEM). An estimation of the economic impacts associated with BRD-related morbidity and mortality was also determined.

Results: During this period, 188,862 steers were on feed. The morbidity rate was 7.05% (13,315/188,862), with mortality at 0.64% (1,214/188,862). The principal causes of morbidity were BRD (6.13%; 11,577/188,862), lameness (0.29%; 550/188,862), trauma (0.21%; 406/188,862), clostridiosis (0.13%; 242/188,862) and polioencephalomalacia, PEM (0.12%; 222/188,862). Predominant causes of mortality were BRD (0.21%; 397/188,862), trauma (0.17%; 329/188,862), clostridiosis (0.13%; 242/188,862), other diseases (0.08/157/188,862) and PEM (0.02%; 46/188,862), resulting in 32.7% (394/1,214), 27.1% (329/1,214), 19.9% (242/1,214), 12.9% (157/1,214) and 3.79% (46/1,214) respectively, of the animals that died during this period. When all sick cattle were considered, BRD (86.9%; 11,577/13,315) was the principal cause of morbidity, followed by lameness 4.13% (550/13,315), trauma 3.05% (406/13,315), and clostridiosis 1.82% (242/13,315). BRD-associated mortality was estimated at \$14,334.00/10,000 cattle; morbidity due to BRD resulted in \$16,315.40/10,000 cattle. It was projected that the economic effects due to BRD-associated morbidity in Brazil were \$6.31 million/annum, while losses due to mortality were \$5.54 million, resulting in an annual loss of \$11.85 million.

Conclusions: This is the first study that investigated the incidence of BRD in feedlot cattle from Brazil, and the results herein described indicate that BRD contributed significantly to the development of mortality and morbidity of cattle on feed.

P01-001-022

Evolution of seroprevalence for BHV-1 gE in a French herd vaccinated with a live bovine herpesvirus type 1 marker vaccine.

René Fournier¹ Loïc Oliviero¹ O Bruyninx² Eric Meens³ T Rambaud⁴ Siddhartha Torres^{5*}

¹MSD Santé Animale, Beaucouzé, ²Veterinary Practice, Forges Les Eaux, ³G.D.M.A., Bois-Guillaume, ⁴L.D.A., Rouen, France, ⁵Merck Animal Health, Madison, United States

Objectives: The objective of the present field study was to determine the evolution of seroprevalence for Infectious Bovine Rhinotracheitis (IBR) due to Bovine Herpesvirus type 1 or BoHV-1 (BHV-1 gE) in a French herd vaccinated with a live bovine herpesvirus type 1 marker vaccine.

Materials and Methods: The herd vaccination programme started in November 2008 in a large beef herd located in Normandy with a high seroprevalence of IBR. 74 % of heifers aged from 14 to 30 months and vaccinated with a live marker vaccine (Bovilis® IBR Marker Live, MSD Santé Animale) had BoHV-1 gE antibodies before beginning the herd protocol. All cattle within this herd were vaccinated with the same live

marker vaccine. Calves were vaccinated intranasally at two weeks of age, revaccinated at three months and thereafter boosted every six months. Cattle aged three months or more were vaccinated once intramuscularly and revaccinated every six months. All the animals aged between 12 and 48 months were sampled every six months to evaluate their BoHV-1 gE antibody status. Biosecurity measures were also applied and every positive animal was removed.

Results: In this field study, a total of four hundred animals, including calves, were vaccinated with the live marker vaccine. Results showed that the incidence of new seroconversion (BHV-1 gE seroincidence) decreased over time (from 5 percent BHV-1 gE seroincidence in November 2009 to 0 percent BHV-1 seroincidence in November 2012). As a result, the herd BHV-1 gE seroprevalence decreased also over time (from 50 percent BHV-1 gE seroprevalence in May 2009 to 0 percent BHV-1 gE seroprevalence in May 2014).

Conclusions: It can be concluded that vaccination with a live IBR marker vaccine could significantly contribute, if associated to hygienic measures and to a specific herd management, to the eradication of BoHV1 in a large herd with a high seroprevalence under field conditions.

Mineral supplement responses of grazing cattle under tropical conditions in Cuba

Gutiérrez Odilia¹, Gutiérrez B. Odilia² and Mineral group of Animal Science Institute

¹Fisiología y Bioquímica, Instituto de Ciencia Animal, San José de las Lajas, Mayabeque, ²Fisiología y Bioquímica, Instituto de Ciencia Animal, San José de las Lajas, Mayabeque, Cuba

Objectives: In Cuba, the grazing cattle are developed in areas with different nutritional deficiencies such as nitrogen and mineral elements. The objective of these work was determine the principal mineral deficiencies in dairy grazing cows for to know the mineral supplement responses of grazing cattle under tropical conditions.

Materials and Methods: An interesting work was conducted during 15 years in West, Center and East regions where the principal mineral deficiencies in pastures were: nitrogen, calcium phosphorus, copper, zinc and manganese. Mineral premixes were supplemented to grazing cattle depending of productive and reproductive purpose and the principal deficiency founded in previous analysis of pastures. Dry matter, nitrogen and organic matter were determined as AOAC (2005), macro and micro minerals by atomically absorption and phosphorus for colorimetric method.

Results: Increase in milk production and composition such as a better alimentary efficiency were found when appropriate mineral premix was offered. Five milking enterprise from west areas presented acid soils with organic matter content above 3% and pastures middle values of nitrogen, phosphorus, copper and zinc of 11.2, 10.4, gkg⁻¹; 8 and 20 mgkg⁻¹ respectively. A mineral premix containing deficient minerals improves milk production in one kg/cow/day. Cows and heifers in Center Region presented low levels of blood copper and reproductive disorders which were improve with injectable copper. East Region presented soils with pH between 6-7 and pastures protein levels ≥ 8%. Blood indices of cows and heifers showed low levels of hemoglobin, hematocrit, phosphorus, copper and total proteins which were better when a new mineral premix was offered.

Conclusions: In conclusion, it was necessary a mineral premix (calcium, phosphorus, sodium magnesium and microelements) addition in grazing cattle under pastures of poor quality in order to increased productive and reproductive indicators.

Comments: Keywords: mineral premix, milk production, cattle.

P02-002-097

An assessment of immune and stress responsiveness in Holstein-Friesian cows selected for high and low feed conversion efficiency

Josh Aleri¹, Brad C. Hine², Michael Pyman¹, Peter Mansell¹, Bill Wales³, Bonnie Mallard⁴, Andrew D. Fisher¹

¹Faculty of Veterinary and Agricultural Sciences, University of Melbourne, Werribee, ²Agriculture Flagship, CSIRO, Armidale, NSW, ³Agriculture Research and Development Division, Department of Economic Development, Jobs, Transport and resources, Ellinbank, Victoria, Australia, ⁴Department of Pathobiology, Ontario Veterinary College, University of Guelph, Ontario, Canada

Objectives: selecting animals for enhanced immune responsiveness and feed conversion efficiency are herd improvement strategies. Information on the relationship between immune responsiveness and feed conversion efficiency in dairy cattle is limited. Therefore, to provide insights into the potential benefits of selecting animals with enhanced general immune responsiveness the objective of this study was to assess the relationships between immune responsiveness, stress responsiveness and feed conversion efficiency of cows identified as extremely high and low feed conversion efficiency phenotypes.

Materials and Methods: The study utilized 16 Holstein-Friesian cows in their 3rd - 4th lactation, and identified as having either extremely high (n = 8) or extremely low (n = 8) feed conversion efficiency. The high feed conversion efficiency group had a mean of -0.825 ± 0.29 kg/DM/day residual feed intake and the low feed conversion efficiency group had a mean of 0.699 ± 0.19 kg/DM/day residual feed intake. Residual feed intake was defined as the difference between an animal's actual feed intake and its expected feed intake which was determined by regression of dry matter intake against main body weight and growth rate. A commercial vaccine was used to induce measurable antibody (AMIR) and cell-mediated (CMIR) adaptive immune responses and assess general immune responsiveness at days 0, 8 and 10 of the immunization protocol. AMIR were assessed using ELISA whereas CMIR were assessed using delayed type hypersensitivity reactions. Stress responsiveness was assessed by measuring changes in plasma cortisol concentrations in response to yarding and handling.

Results: Comparisons of AMIR measures revealed no significant differences between the high and low feed conversion efficiency phenotype groups on day 0, 8 or 10 (P=0.585, 0.978 and 0.343) respectively. Similarly, no difference was observed between feed conversion efficiency phenotype groups for CMIR measures (P=0.546). Pairwise comparisons revealed that AMIR measures were significantly higher on day 8 and 10 compared to day 0 (P=0.0001 and P=0.036, respectively). Differences between day 8 and 10 AMIR measures were not significant (P=0.975). Lower cortisol concentrations were observed in the high feed conversion efficiency phenotype cows as compared to their low feed conversion efficiency group on day 10 but only approached significance (P=0.079). No significant difference in cortisol levels were observed between the groups on day 8 (P=0.394) despite the low feed conversion efficiency group recording higher cortisol concentrations as compared to the high feed conversion efficiency group. Furthermore cortisol responses were significantly increased on day 10 relative to day 8 (mean difference = -2.80 nmol/L, 95% CI $(-5.11 - -0.49)$ nmol/L, P=0.021). A significant negative (but favourable) relationship was observed between AMIR and stress responsiveness, (R=-0.44, P=0.043) in the current study. In contrast, stress responsiveness and CMIR were not correlated (R=0.135, P=0.309).

Conclusions: To the author's knowledge, the relationship between immune responsiveness phenotype and feed conversion efficiency phenotype has not been investigated previously in dairy cattle. This study provides preliminary evidence that cows selected for feed conversion efficiency may have improved stress coping abilities and immune responsiveness. Results from this study support our hypothesis that enhanced immune responsiveness is correlated with reduced stress responsiveness, however validation of our findings in a larger population of animals is required.

Improving colostrum management in dairy calves by blood IgG measurement combined with recording and analyzing colostrum management data.

Inge Nijhoving ¹Siddhartha Torres ²

¹MSD Animal Health, Boxmeer, Netherlands, ²Merck Animal Health, Madison, United States

Objectives: Neonatal Calf Diarrhea (NCD) is a common disease affecting newborn calves. To reduce the incidence of NCD it is important to use a preventive approach. Vaccinating the dam is a proven preventive method to increase specific 'protection' and good colostrum management is a crucial element for a newborn calf to get a good start. The aim of the study is to gain more insight in the correlation between colostrum management and blood IgG levels of newborn dairy calves.

Materials and Methods: The study was conducted in The Netherlands using data from a 13 dairy farms. A colostrum management form was used to record data during the first 24 hours after calving (animal identification, calving date, time of calving, time of 1st colostrum feeding, amount of colostrum feed, IgG concentration). Information from a total of 58 dairy calves was recorded in the form and used for analysis. Blood samples from these calves were obtained from 2nd and the 5th day after birth in order to determine blood levels of IgG.

Results: Sixty-two percent of the examined calves had a low blood IgG level (IgG < 15 g/L), the remaining 38% had a high blood IgG level (>15 g/L). Most calves with a low blood IgG level received 5 liters colostrum or less in the first 24 hours, which was significantly lower compared to the calves with a high blood IgG level. There were no differences between calves with high and low IgG blood level in the interval birth-first feeding (OR=1.2, p=0.78, 95% ci 0.3-4.9), the interval second-third feeding (OR=1.3, p=0.7, 95% ci 0.4-4.6) and the amount of colostrum fed in the second and third feeding (OR=1.1, p= 0.85, 95% ci 0.4-3.4), (OR=1.2, p=0.75, 95% ci 0.3-4.5).

Conclusions: Conclusion of this study is that most calves still don't receive enough colostrum. Most calves with a low blood IgG level received colostrum directly after birth, but a strong trend was seen that the amount of colostrum in the first feeding was not enough and the second feeding was offered too late. Not all farmers milked out the dam completely directly after birth, which raises concerns. This study emphasized that by recording and analyzing colostrum management data in combination with determining the blood IgG level of dairy calves, a customized advice can be given.

Automated measurement system of body temperature in calves using infrared thermography

Tohru Suzuki ¹Yuchi Yoshinaga ²Masafumi Miata ²Syoichi Kimura ²Ken Katsura ¹

¹National Institute of Animal Health, NARO, Tsukuba, ²Nippon Avionics Co., Ltd., Tokyo, Japan

Objectives: Infectious diseases are a major concern in cattle industry.

Young calves are susceptible to infection of pathogens because of their immature immune system, and hence they often lead to a death with diarrhea or pneumonia after birth.

Early detection of sick animal is important to implement effective treatment and disease control. Many of sensing techniques of health condition in animals are invasive, and they usually require capture of animals, and collection of clinical samples. Infrared thermography is a non-invasive technique, and is useful for early detection of animals with infectious diseases by monitoring body temperatures continuously.

Materials and Methods: Young Holstein or Japanese Black calves (5 to 6 heads per group) managed and maintained by calf feeder in several farms were used in this study. Each group was recorded their clinical signs and amount of milk other than body temperature every day for one month. We tested whether our automated system can distinguish individuals by a visual camera, and can measure their facial, particularly ophthalmic max temperatures by using an infrared camera (InfRec TS9100, Nippon Avio) when calves are drinking milk fed by robots, in order to monitor their health condition continuously. After observation for one month, we analyzed correlation between individual health condition and their ophthalmic max temperature.

Results: In results of tests in several farms, we confirmed that our system can clearly distinguish individuals in each group and measure their ophthalmic max temperatures automatically and stably by using the infrared thermography during drinking milk. In addition, our data indicated that the measured max temperatures were strongly reflected by animal health condition. Moreover, this system has also a function that correct ophthalmic max temperature according to daily fluctuation of ambient temperature by monitoring ambient temperature of animals continuously. Therefore, we can accurately understand individual normal temperature without consideration of ambient temperature of animals by using our system.

Conclusions: Our system would enable to early detection and effective treatment of affected animals by monitoring their body temperature using infrared thermography. Therefore, it would contribute to reducing animal suffering and improving the economic losses in farm.

P02-002-100

A participatory on-farm approach leads to the identification of farm-specific management actions and high implementation rates in organic dairy farms

Margret Krieger ¹Karin Sjöström ²Ulf Emanuelson ²Isabel Blanco Penedo ³Julie E. Duval ⁴Aurélien Madouasse ⁴Nathalie Bareille ⁴Albert Sundrum ¹

¹University of Kassel, Witzenhausen, Germany, ²SLU, Uppsala, Sweden, ³IRTA, Monells, Spain, ⁴Oniris, LUNAM Université, ⁵INRA, Nantes, France

Objectives: In terms of production diseases a considerable proportion of organic dairy farms in Europe do not meet the organic principle of good animal health. Main reasons for the great variation in animal health under organic conditions are different management practices, restrictions in the availability of resources, and a lack of control mechanisms. Numerous studies have concluded that farm-individual approaches involving the necessary expertise and taking into account system dynamics and farm-specific opportunities and constraints are

needed to identify effective measures that are likely to be implemented, both in organic and conventional farms.

Materials and Methods: Organic dairy farms participating in the IMPRO project (impro-dairy.eu) were visited once in 2013 for an assessment of general characteristics, resources, and management procedures. A second visit was carried out in 2014 to conduct a round-table discussion between the farmer, the farm veterinarian and an agricultural advisor. The second visit, which took between 2 and 4 hours, was moderated by a researcher and followed the same procedure on all farms: farm walk, evaluation of the animal health status, system analysis by an impact matrix, cost-assessment of production diseases, identification of areas in need of improvement, discussion of potential management measures, agreement on suitable actions, feedback session. All farms were surveyed 1 year after the second visit by a written questionnaire to assess the level of compliance with the action plans and evaluate the limitations leading to non-compliance.

Results: In total 192 farms were visited. Due to involvement in other project activities 60, 29, 28 and 32 farms in Germany (DE), Spain (ES), France (FR) and Sweden (SE), respectively were part of the final survey and analysed for this report. In 11 cases (8%) no list of actions was agreed upon while suitable actions were identified in the remaining 138 farms, the number of actions ranging from 1 to 22 with a median (m_{ALL}) of 8. Least actions per farm were identified in FR (m_{FR} 2.5) and most in SE (m_{SE} 12). Actions ranged from very general ('improve feeding') to very specific ('use dry-cow therapy in case of positive California Mastitis Test'). The survey response rate was 63.1%. Of the 94 farms that responded, 88 (93.6%) had implemented at least one measure. The number of implemented measures ranged from 0 to 17 and was lowest in FR (m_{FR} 1) and highest in SE (m_{SE} 7). The rate of implementation was highest in FR (m_{FR} 81.7%) and 66.7%, 65% and 18.0% in DE, SE and ES, respectively. Most actions that were not implemented within one year were related to construction. Other limitations were (in order of frequency of response) time constraints, doubts about the effect, excessive costs, absence of the initial problem, implementation of alternative action(s), lack of expertise, and doubts about the appropriateness of the action.

Conclusions: It can be concluded that a structured participatory approach to health planning involving relevant stakeholders and an analysis of the whole farm system, its opportunities and constraints, can result in action plans tailored to the farm-specific situation and likely to be implemented. The limitations emphasise that 1 year is too short to assess the implementation of construction measures. Moreover, they indicate that farmers in Europe are under great economic pressure and that a lack of conviction often keeps them from taking actions to improve animal health. Future research and advisory practice should take these constraints into account.

Comments: This project has received funding from the European Union's Seventh Framework Programme for research, technological development and demonstration under grant agreement n° 311824 (IMPRO).

A study of a bolus system for continuous monitoring of ruminal pH in dairy cows under physiological conditions.

Katharina T. Hille¹·Hannah S. Braun¹·Julia Rosendahl¹·Katrin Mahlkow-Nerge²·Ulrich Meyer³·Friederike Stumpff¹

¹Freie Universität Berlin, Veterinary Medicine, Institute of Veterinary

Physiology, Berlin, ²Fachhochschule Kiel, Agrarwirtschaft, Osterrönfeld, ³Friedrich-Loeffler-Institut, Federal Research Institute for Animal Health, Bundesforschungsanstalt für Tiergesundheit, Braunschweig, Germany

Objectives: Systems to monitor ruminal pH levels of dairy cows aim to contribute to the general dairy herd health management. Besides the frequently used single point measurement techniques, intraruminal continuous pH measurement systems are focusing in particular on the diagnosis of subacute ruminal acidosis (SARA). However, there is increasing evidence suggesting a considerable variability in measured pH depending on the system used. We tested if the accuracy of continuous pH monitoring systems is sufficient to provide reliable data of the ruminal conditions. The benefits and limits of ruminal pH measurements in terms of validity were elucidated.

Materials and Methods: For the present study a continuous measurement system was used in order to record ruminal pH (smaXtec GmbH, Graz, Austria). According to the manufacturer, the accuracy of the applied pH bolus is ± 0.2 and the resolution is ± 0.01 . To examine the accuracy and validity of the system, two different experiments with either six or eight lactating Holstein Friesian cows equipped with a pH bolus were performed.

In the first experiment, 6 cows with an indwelling pH bolus were fed on a performance oriented grass-maize based Total Mixed Ration (TMR). Ruminal pH levels were continuously monitored. 49 days later each cow received a second pH bolus. On day 50 data from both devices were compared over a period of 24 hours and analysed for differences in daily pH-fluctuation.

In a second experiment, 8 fistulated cows with an indwelling pH bolus were fed on a TMR and additional concentrate supplementation. Again, pH values were continuously monitored. At a given time the cows were exposed to an eight hour lasting feed deprivation inducing an increase of the ruminal pH level. Additionally, the pH bolus from each cow was removed for approximately two hours through the ruminal fistula in order to test the accuracy of measurement by incubation in buffer solutions of pH 5 and 7 (39°C). Simultaneously, pH values were also analysed both by direct measurements of the ruminal fluid near the fistula using a pH meter and by obtaining ruminal fluid through a common suction pump, the pH of which was determined immediately afterwards

Results: Despite the considerable variability of the absolute pH value of the individuals, typical daily fluctuations in pH related to feeding, milking and treatments were observed.

In the first experiment, mean values of the pH during week 1 to 4 differed only slightly and showed expected daily changes according to circadian rhythm and feeding strategy of the farm. From week 5, the measured pH values began to decrease slightly, resulting in a pH drop of approximately 0.35 units (between first and 7th week). Comparison of the first and the second pH bolus on day 50 revealed differences ranging from 0.26 to 0.47 pH units with a mean of 0.39 ± 0.08 . Only one pair of devices yielded values that were comparable (-0.09 ± 0.09). The pH values of the first bolus were significantly lower than those measured by the second bolus.

In the second experiment, the 8 hours feed deprivation resulted in a slight increase of pH. Restarting the feeding decreased pH values by -0.84 ± 0.18 units. These changes occurred within 103 ± 22 min and recovery was reached within 24 ± 11 hours.

Removing the bolus through the cow's ruminal fistula and incubating it in artificial buffer solutions with a known pH revealed considerable shifts in accuracy: At pH 7 an average pH of only 6.60 ± 0.39 was measured, at pH 5 the average pH ranged from 4.58 to 5.61. pH values obtained by direct measurement through a fistula (5.52 ± 0.11) and those obtained in ruminal samples after aspiration (5.67 ± 0.31) differed significantly from

the value measured by the pH bolus in the corresponding time (6.39 ± 0.28).

Conclusions: The continuous pH monitoring system used in the study provides reasonably reliable data on the typical daily ruminal pH fluctuation of dairy cows. However, the accuracy in terms of absolute pH values appears less than optimal, so that the impact of continuous pH measurements on herd health may be debatable. Since the diagnosis of SARA strongly depends on absolute pH values during a certain time period, the data provided by continuous pH monitoring systems should be interpreted cautiously.

Optimization of dry cow management can influence natural antibody (Nab) levels and the incidence of postpartum disorders in dairy cows

Sanne Carp-Van Dijken^{1*} and S. Carp-van Dijken, I.M.G.A. Santman-Berends, G. Van Schaik, T.J.G.M. Lam, I.E.M. den Uijl

¹ruminants, Gd Animal Health, deventer, Netherlands

Objectives: Resilience plays an important role in the ability of cows to remain healthy and productive and can be measured by evaluation of immune parameters in cows. In previous research we found that natural antibody levels (NABs) combined with parity, SCC and postpartum disorders in the prior lactation could indicate whether a cow had a low or high risk for developing a disorder in the subsequent lactation. The aim of this study was to evaluate if postpartum disorders could be prevented by management optimisation of dry cows and whether this optimisation resulted in a change in NAB levels and thus in the risk profile of the cows.

Materials and Methods: In 29 Dutch dairy herds milk samples of cows were tested for IgM and IgG NAb levels at each test-day milking from December 2013 to March 2015. From April 2014 on, for each study herd a tailored plan was made to optimize dry cow management by a veterinarian specialized in feed and dry cow management in collaboration with the herd owners. During the optimisation process which lasted until March 2015, the farmers were guided intensively by the veterinarian with at least bi-monthly contact moments (either in person, by phone, app or email).

Besides optimisation, test-day milk recording data, fertility records, identification and registration data and comprehensive data from livestock disease registration systems were available. Digital disease registration contained cow-level records with the disease and the date it was observed by the farmer.

We evaluated whether the amount of postpartum disorders had changed during the period in which optimisation was conducted. A multilevel logistic regression model was used with postpartum disorder as dependent variable and period (before, at the start or during optimisation), parity, quality of optimisation and a random herd effect as independent variables. In addition, a linear regression model was used to evaluate the influence and quality of optimisation on NAb levels during the study period. The quality of optimisation was also used to divide the study herds in three classes, herds that applied all, part of, or none of the optimisation measures as indicated by the veterinarian.

Results: Besides a large variety of herd-specific optimisation measures, three measures could be applied in all herds:

1. Improve intake of dry matter
2. Optimisation of the ration of dry cows

Other optimisation measures were often related to reduction of infection pressure and stress reduction.

During the study period, the percentage of postpartum disorders decreased from on average 21% prior to optimisation to 16% during optimisation (figure 1a). During optimisation cows had a 1.6 (95% CI: 1.1-2.4) times lower probability (odds) to develop a postpartum disorder as compared to the period prior to optimisation.

Figure 1. Percentage of cows with a postpartum disorder (a) and average natural antibody levels (b) in 29 dairy herds, prior to optimisation (before dashed lines (May 2014)).

Higher NAb levels were known to be associated with higher incidence of postpartum disorders. It appeared that the NAb levels of the cows in the study herds decreased significantly in the period in which dry cow management was optimized. The decrease in NAb level was more evident in herds that applied part or all of the optimisation measures compared to herds that did not optimize their management (Figure 1b). Lower NAb levels contribute to a smaller proportion of cows defined as high risk, thus it seemed that the risk profile of cattle for postpartum disease could be changed by optimisation of dry cow management.

Conclusions: Our study showed that it is possible to prevent cows for developing postpartum disorders, from actually getting diseased by optimisation of dry cow management. In addition, by optimising dry cow management the Nab levels in dairy cows decreased resulting in a decreased risk for developing postpartum disorders in the subsequent lactation.

P02-002-103

Diagnostic Validity Of Real Time Measurement Of Reticular Temperature For The Prediction Of Parturition And Estrus In Dairy Cows

Johann Gasteiner^{1*}, Josef Wolfthaler¹, Werner Zollitsch², Marco Horn², Andreas Steinwider¹

¹Research and Education Center Raumberg-Gumpenstein, Irdning, ²BOKU-University of Natural Resources and Life Sciences, Vienna, Austria

Objectives: It is proven that the reticular temperature (RT) in ruminants is representative for the body temperature. In present study the suitability of the (RT) as an indicator for expected parturition and estrus of dairy cows was investigated.

Materials and Methods: 25 parturitions and 43 estruses were recorded. Estrus was confirmed by frequent measurement of milk-progesterone and, retrospectively, by a successful artificial insemination. The RT was measured continuously every ten minutes with indwelling reticular sensors and data were read out by telemetry. The average ambient temperature during the study period was 4.43° C (± 7.86) and the mean RT 39.23° C (± 0.33). In this study the averages of RT-day, 5 days before up to 2 days after estrus, the RT-4 hour averages from 48 hours up to 20 hours after the temperature maximum at estrus and the RT-day averages 10 days before up to 10 days after calving, were analyzed. Time of day, feeding, breed and lactation number were also considered.

Results: RT was sign. influenced by time of day and ambient temperature. RT was also sign. affected by the occurrence of estrus. The mean RT on the day of estrus was 0.15° C higher than the day before. The maximum RT-4-hour average on the day of estrus (39.71° C) was also increased sign. The results for heat detection showed an area under curve (AUC) of 0.81. A sign. effect of parturition on the RT was also found. 48 hours prior to calving RT decreased sign. by 0.43° C. No sign. difference was found between one day before parturition and the day of parturition. Up to a temperature threshold of $\geq 0.40^{\circ}\text{C}$, 100% of the parturitions were detected by RT within 24 up to 48 hours, with a specificity of up to 93%. The prediction of a parturition within 24 and 48 hours showed an AUC of 0.99.

Conclusions: We conclude that continuous RT measurement as used herein is highly suitable for detecting upcoming parturitions and, to a lesser extent, to identify cows in heat. Further results are promising for the early detection of health problems linked with an increase or decrease of body temperature.

Effect of duration and temperature during the delivery of bovine blood samples to the analytical laboratory on metabolic parameters serum assays

Barbara Galmiche¹; Catherine Garnier¹; Laurent Alves De Oliveira^{2,3}

¹IODOLAB, ²Campus vétérinaire de Lyon, VETAGRO-SUP, MARCY L'ETOILE, ³UMRH, INRA, Theix, France

Objectives: Blood samples collected in bovine medicine are often exposed to a range of environmental conditions prior to analysis in a laboratory. The stability of the molecules in the bovine blood is poorly understood. The aim of this study was to determine analyte stability of blood specimens in serum tubes exposed to a range times and two storage temperatures prior to centrifugation.

Materials and Methods: Blood samples were taken in 10 lactating Montbeliarde cows in one farm, 1.5 hours after the morning diet distribution. 17 blood tubes were taken from the jugular vein of each animal. The samples were immediately placed in a cooler box, protected from light, and sent to the laboratory. For each cow, one tube was centrifuged and analyzed in the 3 hours after collection (D0) as controls. 8 samples, uncentrifuged, were placed in a refrigerated chamber at 4°C and 8 samples, left at room temperature (25°C). All tubes were kept sheltered from the light. The day D1, D2, D3, D4, D7, D8, D9, D10, one tube stored at room temperature and one kept cool tube were centrifuged and analyzed (in duplicate). The analysis methods used were HPLC for vitamin A, E, and β carotene or enzymatic colorimetric method with an automated biochemistry analyser (JEOL Biomajesty 6010 with Biomérieux, Diasys, Diacron and Randox kits).

Statistical analysis was performed with the Excel © software. Outliers were removed by the Grubbs test. For each pair number storage day / storage temperature and each parameter, the averages of the 10 cows was compared with the average to D0 by a Student's t test for paired data if the distribution was normal (checked by Shapiro-Wilk test) and the variances equal (verified by Cochran's test) or by test of Wilcoxon signed rank in other cases. The results of stored samples were considered to be different from the value on D0 (reference) if the difference between average of stored samples and D0 average was greater than the measurement uncertainty or if $p > 0.05$.

Results: Assay results are identical to the D0 value during the numbers of days (d) following : (for samples stored at 4°C and 25°C respectively) : Bile acids : 3 d, 3 d ; nonesterified fatty acids (NEFA) 8 d, 1 d ; pancreatic amylase 8 d, 8 d ; aspartate amino transferase (ASAT) 4 d, 2 d ; β carotene 8 d, 8 d ; conjugated bilirubin 2 d, 1 d ; total bilirubin 2 d, 1 d ; β hydroxybutyrate (BOH) 10 d, 4 d ; calcium 10 d, 7 d ; chloride 8 d, 8d ; cholesterol 10 d, 10 d ; creatine kinase (CK) 4 d, 2 d ; total carbon dioxide 8 d, 8 d ; creatinine 9 d, 9 d ; reactive oxygen species production (d- ROMs, a subclass of reactive oxygen metabolites (ROM) used to determine the antioxidant capacity of plasma) 4 d, 1 d ; iron 9 d, 4 d ; gamma glutamyl transferase (GGT) 4 d, 4 d ; glutamate dehydrogenase (GLDH) 10 d, 7 d ; lipase 2 d, 2 d ; magnesium 10 d, 10 d ; serum total antioxidant capability (OXY-adsorben test, measures the ability of a plasma sample to object to a massive oxidative insult induced in vitro by a solution of hypochlorous acid) 10 d, 10 d ; Alkaline phosphatase (PAL) 10 d, 10 d ; Phosphate Inorganic 10 d, 3 d ; Potassium 1 d, 1 d ; Total Protein 10 d, 10 d ; Sodium 4 d, 4 d ; Total Iron-Binding Capacity (TIBC) 10 d, 10 d ; Triglycerides 4 d, 3 d ; Urea 10 d, 3 d ; vitamin A 10 d, 10 d and vitamin E 10 d, 10 d.

The storage temperature has no effect on the duration of biochemical parameters stability for half of the measured parameters, for the others parameters, the stability is better when the sample is kept cool.

Conclusions: The stability of some biochemical indicator is very long, it reached 10 days (Total Protein, BHB, urea, cholesterol, Ca, Mg, Phosphate Inorganic, PAL, GLDH, ...) especially for vitamin A and E deemed fragile. Very few parameters require analysis rapidly after collection (bile acids, bilirubin, lipase). These results show a very good stability of biochemical parameters in cattle. The use of biochemical assays should not be limited even if the delivery times in the laboratory is several days. However, the laboratory should check the temperature on receipt of samples to ensure the reliability of the value (NEFA, CK, d-ROMs, potassium, urea).

Diversity of behavioural patterns displayed by an autumn calved, recently weaned cohort of dairy calves in SE QLD dairy herd

Bome Kealeboga¹; John Alawneh^{1,*}

¹School of Veterinary Science, University of Queensland, Gatton, Australia

Objectives: Timely detection of morbid animal has a detrimental effect on animal productivity and animal welfare¹. Movement trends have been extensively studied in wildlife to monitor annual migration and prey-predator interactions.^{2,4} Different species of animals develop distinct movement trajectories that can be monitored overtime and used as indicator of health.⁵ The objective of the study was to describe diversity of the movement patterns displayed by a recently weaned cohort of dairy calves soon after weaning and to assess the feasibility of collecting such data as a proof of concept to monitor dairy calves' movement patterns.

Materials and Methods: This pilot cohort study was conducted on dairy calves at the University of Queensland, Gatton campus, South East Queensland in September 2015. There were 14 Holstein calves comprised of six males and eight females. The age range for these calves was 8-9 weeks old. The calves were fitted with GPS data loggers (Igot-U GT600, Mobile Action Technology Inc, Taipei, Taiwan) to capture coordinates, distance, time and speed. Each calf was identified by an ear

tag. The combination of ear tag and GPS unit serial number was used as a form of identification during the study. The data loggers were pre-set to record data at twenty seconds interval over a twenty four hour period for the duration of three days. This interval reduced chances of omitting little movements.⁶ The following variables were calculated to describe the movement patterns of the calves; distance, rate of movement (ROM), angles of turns and linearity ratio.⁷ The mean and standard deviation were calculated for all the variables, excluding linearity ratios. A within group sum of the squares plot was used to identify clusters in the trajectory data set. A k-means cluster analysis was used to divide relocations into one of the identified clusters. Univariate analyses of variance (ANOVA) were used to test for the significance of each matrix variables in characterising calves movement pattern. Analyses were done using the *fpc*⁸ and *adehabitat* packages⁹ in the R package.

Results: Overall, there were 17532 relocations made by the 14 calves with 618 being the smallest number of relocations. The highest number of recorded relocations was 3725. There was a significant difference ($P < 0.001$) in the number of relocations made by the individual calves. There were eight calves that recorded over 1000 relocations each against only three registering relocations less than 1000 relocations. The number of relocations at about 250 were recorded at 6pm with the next other highest number of relocations captured at 8 and 9pm. The highest numbers of relocations occurred between afternoon and night ($P < 0.01$). Three distinct movement patterns were identified using cluster analysis: a) the foraging pattern cluster characterised by short distance movements over a wide geographic area with big turning angles; b) travelling pattern cluster which is associated with large distance movements with small turning angles and high speed; and c) the resting or bedding pattern cluster.

Conclusions: There was a significant difference in the number of relocations and movement patterns made by the individual calves. Significant movement activities from the study animals occurred mostly in the afternoon and at night. Three distinct movement patterns have been identified with significant differences in distance travelled, rate of movement and linearity ratios. This study shows that despite the complexity of animal movement behaviours collecting movement data is feasible and could potentially be developed further to enhance remote monitoring of health and wellbeing of dairy calves.

Evaluation of quality and management of colostrum on dairy farms in Spain

Carlos Carbonell¹Laura Ferreira¹Laura Elvira^{1*}

¹MSD Animal Health, Madrid, Spain

Objectives: The quality and management of colostrum is the most important risk factor for the health of the dairy calf. However, to our knowledge no previous study has evaluated the quality and management of colostrum on Spanish dairy farms. The objective of this study was to evaluate colostrum quality and frequency of failure of passive transfer of immunity to newborn calves.

Materials and Methods: Twenty five dairy farms located in different regions of Spain were selected. In each farm a three step program was implemented: 1) epidemiological questionnaire including main critical points for colostrum management on farm; 2) sampling of colostrum (a minimum of five colostrum samples per farm) and sera from newborn calves (a minimum of five calves of 24h to 6 days old per farm); and 3)

individual and overall analysis of the results and recommendations to improve colostrum management.

The samples of fresh, frozen or refrigerated colostrum were collected just before the first administration to the newborn calf, according to normal on farm practices. Then, the colostrum was analyzed to determine its composition (fat, protein, somatic cell count (SCC)); microbiological quality (total plate count (TPC) and coliform count (CC)); and immunological quality (IgG concentration, mg/mL). In addition, serum samples were taken from calves. Whenever possible, the sampled calves were the ones previously fed the sampled colostrum. The serum was analyzed to evaluate FPT through direct measure of IgG (g/mL) and also indirectly by total proteins (g/dL) and Brix refractometry (%).

Results: This information will be very useful to identify the proportion of colostrum that meets the minimum standard IgG concentration (50 mg IgG/mL in colostrum); and also to calculate the quantity of colostrum we should recommend to feed to the calves in order to reach the necessary IgG absorption (10 mg IgG/mL in calves sera to avoid FPT. On the other hand, it will allow an evaluation of the colostrum management on farm mainly based on: the level of contamination (bacteriological count), the milligrams of IgG administered in first colostrum feeding (based on its quality, quantity and time of administration) and the prevalence of FPT in newborn dairy calves (1-7 days old).

As the study is still in process, the final results and conclusions will be completed and sent to the WBC organization by February 2016 and presented at the congress.

Conclusions: This information will be very useful to identify the proportion of colostrum that meets the minimum standard IgG concentration, calculate the quantity of colostrum recommended in calves sera to avoid FPT. On the other hand, it will allow on farm colostrum management evaluation mainly based on: the level of contamination (bacteriological count), amount of IgG administered in first feeding and the prevalence of FPT in newborn dairy calves (1-7 days old).

As the study is still in process, the final results and conclusions will be completed and sent to the WBC organization by February 2016 and presented at the congress.

P02-002-107

Metabolic status of F1 Holstein x Gir dairy cows during transition period in two different seasons

Tiago Facury Moreira^{1*}Rodrigo M. Meneses¹Elias J. Facury Filho¹Antônio U. Carvalho¹Jose A. U. Zambrano¹

¹Department of clinical and veterinary surgery, Federal University of Minas Gerais, Belo Horizonte, Brazil

Objectives: Brazil has a seasonal milk production due to differences in the climate and food supply. In Minas Gerais the summer period is hotter and rainy with higher grazing availability but heat stress can be very severe. In winter the temperature are mild and there is almost no rain. In this tropical condition the crossbreed F1 Holstein x Gir is proving to be a good alternative for milk production. Thereafter, our works focus on clarifying the metabolic pattern of F1 Holstein x Gir dairy cows during the most critical time in the lactation cycle, the transition period and compare their performance in two seasons.

Materials and Methods: The research took place at a dairy farm located in Minas Gerais State with a herd of 120 lactating cows producing 2,000

liters of milk/ day. We took blood samples from 15 cows during summer (January to April) and 13 cows during winter (May to August). All cows were crossbred ½Holstein ½ Gyr, pluriparous, with lactation order from second to the fifth with average daily milk production of 24L in both seasons. Cows remained in mixed paddocks and received total mixed ratio of concentrate and corn silage twice a day. The Ethics Committee on Animal Experimentation of Universidade Federal de Minas Gerais approved the project.

We took blood samples by puncture of the coccygeal vein weekly during the prepartum beginning in the fourth week before calving expected date, one sampling 24 hours after calving, and in the second, fifth, 10th, 15th, 21th and 30th days postpartum. Thereafter, we conducted analyses of triglycerides, cholesterol, glucose, gamma-glutamyl transferase (GGT), lactate dehydrogenase (LDH), aspartate aminotransferase (AST), non-esterified fatty acids (NEFA) and beta-hydroxybutyrate (BHB) using the technique of spectrophotometry in automatic device and commercial kits.

We used cutoff points of 1.2 mmol/L of BHB for subclinical cetose diagnose and 0.4 mmol/L of NEFA in prepartum and 0.7 mmol/L in postpartum for animals with higher risk for diseases.

The design was a split plot arrangement in which the seasons consisted of plots and times of blood collection the subplots. We used Scott-Knott test for time of assessment and by SNK test for comparison between seasons.

Results: The season had a great influence in the metabolic status seeing that only AST, NEFA and BHB had no variation. Glucose was higher in winter during the whole period. LDH was higher in summer during postpartum. Cholesterol was lower in winter than in summer during the first week prepartum and calving day.

Sometimes, more important than the difference in concentration is the difference in the patten of the metabolites during the transition period between the seasons. On this aspect, almost all evaluated metabolites had a different patten with the exception of glucose, NEFA and BHB.

The mean concentration of NEFA and BHB never reached the cutoff points, but a high number of cows had experienced subclinical cetose or had concentrations of NEFA above the limit. In total, 40.0% of animals had subclinical cetose and 46.67% had high levels of NEFA in winter, while in summer 53.85% of animals had subclinical cetose and 30.77% had high levels of NEFA. It is important to note that the frequency of animals above cutoff points for NEFA and BHB does not follow the same pattern of the mean concentration. This means that the data have to be analyzed by the two ways.

Regarding the sampling time, all liver enzymes and cholesterol increased their activity and concentration after calving while glucose and triglycerides concentrations decreased due to the use for milk synthesis. NEFA concentrations increased one week before calving, reached 0.45 mmol/L at 5th day and decreased 10 days after calving. BHB concentrations increased on the calving day reaching their peak of 0.90 mmol/L on the 5th day.

Conclusions: The metabolic profile of F1 Holstein x Gir cows in semi-confined system differ greatly between summer and winter, reflecting the great difference especially in environmental conditions.

The metabolic status of crossbred ½Holstein ½ Gyr dairy cows in the transition period appeared very similar to the patten presented by cows with a high Holstein composition in similar conditions. This may be due to the genetic selection and consequently increased milk production.

An alarming number of cows had experienced subclinical cetose and high NEFA concentrations, showing that this animals had a greater chance for developing other diseases.

Genetic characterization of antimicrobial resistance in *Staphylococcus aureus* cultured from bovine mastitis cases in Northwest China

Feng Yang^{1,*}

¹Husbandry and Pharmaceutical Sciences of Chinese Academy of Agricultural Science, Lanzhou, China

Objectives: *Staphylococcus aureus* is the most common etiological pathogen of bovine mastitis. The resistant strains make the infections difficult to treat. The objective of the present study was to characterize the genetic nature of the antimicrobial resistance-encoding genes in *S. aureus* cultured from bovine mastitis in Northwest China in 2014.

Materials and Methods: A total of 44 *S. aureus* were isolated in this study. These included 32 strains isolated from clinical cases and 12 strains isolated from subclinical cases. The regions and number of isolates included Gansu (23), Qinghai (11) and Ningxia (10). Mastitis infection was confirmed by California Mastitis Test (CMT). Milk samples were collected aseptically for bacteriological assay. Before sampling, the first streams of milk were discarded, and teat ends were disinfected with cotton swabs soaked in 70% [v/v] alcohol and allowed to dry. Then a 5 mL secretion was collected into a sterile 10 mL tube. Any samples that were not processed immediately were kept at 4 °C for microbiological examination within 18 h of collection.

Results: Susceptibility to a panel of antimicrobial compounds was determined by disc diffusion and the corresponding resistance-encoding genes were detected by polymerase chain reaction (PCR). Phenotypic resistance among these isolates was found to penicillin (84.09%), erythromycin (20.45%), tetracycline (15.91%), gentamicin (9.09%), tobramycin (6.82%), kanamycin (6.82%), and methicillin (2.27%). In total, 9.09% of the *S. aureus* isolates were classified as multidrug resistant. In addition, the genotypes underpinning resistance to rifampicin (100%, rpoB), penicillin (95.45%, blaZ), tetracycline (22.73%, tetK, tetM, alone or in combination), erythromycin (22.73%, ermB or ermC), gentamicin/tobramycin/kanamycin (2.27%, aacA-aphD), methicillin (2.27%, mecA) and vancomycin (2.27%, vanA) were also identified. Resistance to tetracycline was attributed to the genes tetK and tetM ($r = 0.558$, $P < 0.001$).

Conclusions: Thus study noted high-level geno- and phenotypic antimicrobial resistance in *S. aureus* isolates from bovine mastitis cases in Northwest China and confirmed that genotype resistance cannot be used as a diagnostic indicator for phenotypic antimicrobial susceptibility patterns.

The effect of gradual weaning and breed on the blood mRNA transcriptome of artificially reared Holstein-Friesian and Jersey calves

Dayle Johnston¹ Paul Cormican¹ Matthew S. McCabe¹ David A. Kenny¹ Sinead M. Waters¹ Mark McGee³ Alan K. Kelly² Bernadette Earley^{1,*}

¹Animal and Bioscience Research Department, AGRIC, Teagasc,

Grange, Dunsany, Co. Meath, ²University College Dublin, School of Agriculture Food Science and Veterinary Medicine, University College Dublin, Belfield, Dublin 4, ³Livestock Systems Research Department, AGRIC, Teagasc, Grange, Dunsany, Co. Meath, Ireland

Objectives: Holstein-Friesian and Jersey are the predominant dairy breeds in Ireland. Variance in haematological profiles, expression of genes implicated in immune responses and *in vitro* neutrophil activity has been observed between these calf breeds. Weaning was reported to induce a pro-inflammatory stress response in abruptly weaned beef calves. However, limited literature is available on the dairy calf immune response to weaning. Therefore, the objective of this study was to examine the effect of (i) gradual weaning and (ii) breed, on the whole blood mRNA transcriptome of artificially-reared Holstein-Friesian and Jersey calves using RNA-Seq.

Materials and Methods: Holstein-Friesian (n=8) and Jersey (n=8) bull calves were group housed and individually fed milk-replacer and concentrate, using an automatic feeder, for 56 days. During the pre-weaning period, calves were offered 0.8 kg milk replacer (6 litres (l) at 133.33 g/l) and ad libitum concentrate. Prior to weaning (day (d) 0), milk-replacer was gradually reduced over the preceding 13 days (d -13 to d -1) and by d -1 all calves were consuming at least 1 kg of concentrate per day for three consecutive days. On d 0, milk-replacer was eliminated from the diet of all calves. Calves were blood sampled into Tempus Blood RNA Tubes on d -14, 1, and 8, relative to d 0. Total RNA was extracted from whole blood. Forty-eight individual libraries were prepared, validated, pooled, and sent to Clinical Genomics (Canada), for RNA sequencing on an Illumina HiSeq. Forty million 76 bp paired end reads were sequenced per library. Raw sequence reads were assessed for quality using FastQC. Reads were aligned to the bovine genome UMD3.1 using the STAR aligner. Read counts were generated using htseq-count. Differential gene expression was determined using EdgeR. Pathway and downstream biological functional effects analyses were performed within Goseq using Kyoto encyclopaedia of genes and genomes (KEGG) and Ingenuity® Pathway Analysis, respectively, on statistically significant (P<0.05) differentially expressed genes (DEGs), with a false discovery rate (FDR) of 10% and a fold change of ≥ 1.5 . A 10% FDR cut-off was implemented on the results of the pathway analysis using Bioconductor's qvalue package.

Results: There were no DEGs in response to gradual weaning (i.e. within breed between blood-sampling days). The data therefore suggests that gradual weaning of artificially-reared dairy calves does not compromise their welfare. At a false discovery rate of 10% and with a ≥ 1.5 -fold change, 550 DEGs were detected between Holstein-Friesian and Jersey calves on d -14, 490 DEGs on d 1, and 411 DEGs on d 8, respectively. Nine, five and five, KEGG pathways were over-represented among the DEGs between the two breeds on d -14, d 1, and d 8, respectively (P<0.01; Q \leq 0.1). The cytokine-cytokine receptor interaction and the neuroactive ligand-receptor interaction pathways were over-represented between breeds on all days (P<0.01; Q \leq 0.1). These pathways contained immunological genes down-regulated in Jersey relative to Holstein-Friesian calves which are involved in cell signalling and monocyte and T lymphocyte activation, chemotaxis and phagocytosis. The results of the downstream biological functional effects analysis also suggested decreases in cell signalling activity along with chemotactic and phagocytic functions for Jersey relative to Holstein-Friesian calves, on all days. Therefore Holstein-Friesian and Jersey calves differ in transcription of many immune response genes under artificial rearing conditions without exposure to experimental challenge with pathogens.

Conclusions: In conclusion, the data suggest that gradual weaning of artificially-reared dairy calves does not compromise their welfare, evidenced by the lack of expression changes in genes involved in immune and/or stress responses. Additionally, these results demonstrate

transcriptional down-regulation of genes involved in cell signalling and immune responses in Jersey compared with Holstein-Friesian calves. Knowledge of breed-specific immune responses could enable improved health management practices which could be better tailored towards the specific disease sensitivities of Holstein-Friesian and Jersey calves.

Herd Health Management: Dairy

P02-002-110

Relationships between rumination pattern, time of calving and drenching in dairy cows

Lea Lenart ¹; David Bujak ¹; Tamas Kis ²; Otto Szenci ¹; András Horváth ¹

¹Szent István University Large Animal Clinical Research Group, Hungarian Academy of Sciences, Üllő, ²Dózsa Mg Zrt. Tass, Tass, Hungary

Objectives: The objective of this study was to monitor the rumination pattern during the peripartur period in pluriparous dairy cows. The study also aimed to examine the effect of postpartum drenching on rumination times.

Materials and Methods: The study was carried out on a commercial dairy farm and involved 63 Hungarian Holstein Frisian cows. The rumination time was continuously recorded by using an automatic system (Hr-Tag, SCR Engineers Ltd., Netanya, Israel), which were placed on the cows approximately 2 weeks before calving and they were removed 4 days after calving. The data were calculated and summarized in 2-hour intervals. The postpartum drenching (D) was performed on 32 cows randomly, and the control group (C) consisted of 31 cows. The time of calving was recorded in 44 cows. Cows in the D group were drenched with a nutritional supplement consisting of 14% calcium, 42% propionate, 6% magnesium, 6% potassium, 3% sodium, 9% chloride and 20% yeast solved in 25 liters of lukewarm water. Drenching was performed three times approximately 24 hours apart. The exact time of the drenching was recorded. The first drench had to be done in the first 24 hours after calving. Cows in the group C were handled exactly the same way except for the drenching.

Results: There is a tendency toward a decreased rumination time from 8 to 10 hours to 6 to 8 hours before calving (17.2%, P=0.055). Rumination time decreases significantly from 6 to 8 hours before calving to 4 to 6 hours before calving (45.5%, P<0.001), and another significant decrease could be detected between 4 to 6 hours and 2 to 4 hours before calving (58.5%, P<0.001). A non-significant decrease could be found in the 2-hour interval in which the calving proceeded compared to the previous interval (2 to 4 hours before calving). The rumination time resumed the values prior to the first decrease in 24 to 28 hours after calving. After summing up the daily rumination times, a strongly significant decrease was detected on the day of the calving compared to the previous day (P<0.0001). The rumination times of the cows in the D group significantly decreased at the time of drenching (37%, P<0.05) compared to the controls. The difference could also be detected in the next 4 to 6 hours (P<0.05).

Conclusions: We can conclude that the automatic measurement of rumination time is useful to predict the time of calving both on daily and hourly level. Drenching, however, doesn't seem to have a positive effect on rumination times immediately after the treatment.

Herd Health Management: Dairy

P02-002-111

Modeling Lactation Curve For Milk Fat To Protein Ratio In Holstein Cows

Navid Ghavi Hossein-Zadeh^{1,*}¹Department of Animal Science, University of Guilan, Rasht, Iran, Islamic Republic Of

Objectives: The aim of this study was to examine seven empirical mathematical models (Brody, Wood, Dhanoa, Sikka, Nelder, Rook and Dijkstra) currently used to fit 305 day standard lactations to evaluate their efficiency in describing the lactation curve for milk fat to protein ratio (FPR) in the first three lactations of Iranian Holsteins.

Materials and Methods: Data were 8,103,044 test-day records for FPR from the first three lactations of Iranian Holstein cows which were collected on 2392 dairy herds in the period from 1991 to 2014 by the Animal Breeding Center of Iran. Each model was fitted to monthly FPR records of dairy cows using the NLIN and MODEL procedures in SAS and the parameters were estimated. The models were tested for goodness of fit using adjusted coefficient of determination, root means square error, Durbin-Watson statistic (DW), Akaike's information criterion (AIC) and Bayesian information criterion (BIC).

Results: The highest peak of FPR was observed in early lactation, which was followed by a decline as the lactation progressed and an increase toward the end of the lactation period. For the first three parities, Dijkstra model provided the lowest AIC and BIC values, but Nelder model had the greatest values of AIC and BIC for the first three parities. Therefore, Dijkstra equation provided the best fit of FPR for the first three parities of Holstein cows, but Nelder model provided the worst fit. According to DW values, it seems that there was only a slight or no problem of residual autocorrelation for FPR in this study.

Conclusions: The change in FPR over the lactation might be an appropriate selection criterion in order to improve the energy status. Evaluation of the different models used in the current study indicated that non-linear functions were adequate for fitting monthly FPR records of Holstein cows.

Herd Health Management: Dairy

P02-002-112

Effect of Ultrasonographic Lung Lesions on Milk Production in Adult Holstein Dairy Cattle

Muireann Conneely^{1,*}Theresa Ollivett¹Jane Riemann¹Nigel Cook¹Sheila McGuirk¹¹Department of Medical Sciences, University of Wisconsin-Madison, Madison WI 53706, United States

Objectives: Immune system suppression related to parturition and the onset of lactation increase the susceptibility of dairy cows to infectious disease such as pneumonia. Thoracic ultrasound is a practical means of identifying lung lesions which have been associated with poor performance in dairy calves. Currently, there is a paucity of research evaluating the impact of pneumonia on future performance in lactating dairy cattle. The objectives of this study were to investigate the prevalence of ultrasonographic lung lesions and their impact on milk production in recently fresh Holstein cows.

Materials and Methods: The study was conducted April to October 2015 on a commercial dairy with a high historical rate of pneumonia (12% in 2014) in Wisconsin, USA. Fresh Holstein dairy cows (n=554) were enrolled in the study during twice-weekly farm visits. At each visit, a thoracic ultrasound scan was performed once per cow between 4-7 days in milk (DIM). A portable variable frequency linear ultrasound scanner was used to scan the 10th to 4th intercostal spaces on both sides of the thorax. A score (US score) was assigned based on the ultrasonographic finding, as follows: 0) only normal lung tissue visualized, 1) lobular pneumonia in one or more lobes (limited area of focal consolidation involving less than an entire lobe), 3) lobar pneumonia (one or more lobes entirely consolidated). Individual daily milk weights for each cow were recorded and 60 day milk yield was calculated. Blood β -hydroxybutyrate (BHBA) concentration of each cow was recorded between 7-10 DIM. A fixed effects linear regression model was fit using backwards elimination and commercially available software. The primary predictor of interest was US score and the primary outcome was 60 day milk yield. The final model also included parity (parity 1 and parity 2+), treatment for illness in the first 65 DIM, BHBA, and parity*US score interaction. Clinical cases of pneumonia were treated according to farm protocols by farm staff that were blinded to ultrasound status. This study was approved by the University of Wisconsin Institutional Animal Care and Use Committee.

Results: Nine of 554 cows (1.6%) were treated for clinical pneumonia by farm staff. Thirteen of 554 cows (2.4%) were diagnosed with ultrasonographic lobar pneumonia. The prevalence of lobular lesions was 64% (n=353). Approximately one third (34%; n=188) had no ultrasonographic lesions. Two of the 13 cows with lobar pneumonia were treated for clinical pneumonia by farm staff. Conversely, 2/3 cows that were treated between 4-7 DIM for clinical pneumonia did not have lung lesions. In general, 60 day milk yield was greater for parity 2+, than cows in their first lactation (P < 0.001). The effect of US score on 60 day milk yield differed by cow parity (P = 0.02). First lactation cows with lobar lesions had a lower 60 day milk yield (3217 lb, SE 404 lb; n=3) than those with normal lungs (4125 lb, SE 65; n=92) or lobular lesions (4270 lb, SE 76 lb; n=132). Sixty day milk yield was not affected by lung lesions in parity 2+ cows. Other factors impacting 60 day milk yield included treatment for illness and hyperketonemia. Cows treated for an illness produced 230 lb, SE 70 less milk during the first 60 DIM than untreated cows (P = 0.001). Sixty day milk yield increased as BHBA increased, up to 2.9 mmol/L, after which it decreased (P < 0.01).

Conclusions: To the authors' knowledge, this is the first study to demonstrate the negative impact of ultrasonographic lung lesions on milk production and highlights the difficulty in diagnosing pneumonia, as cows with lung lesions were not consistently identified by farm staff. Such discrepancies result in failure to initiate appropriate therapy or the unnecessary treatment of cows lacking lung lesions. This is particularly important in light of recent concerns regarding proper drug use, antimicrobial resistance, and food safety. Future studies should evaluate the impact of treating cows with ultrasonographic lung lesions on milk yield.

Barcelona, Bellaterra-08193, ²Dpt. Reproduccion, INIA, Madrid,
³Centre Veterinari Tona, Tona (Barcelona), Spain

Objectives: Dairy farms are facing difficulties due to high feeding costs, and low milk prices and profits. The need to improve the competitiveness of the dairy enterprise requires decisions that are often difficult to evaluate because they are highly dependent on many economic and technical factors and their interactions. These complex interactions can only be predicted by mathematical modeling. The objective of the present project is to present a stochastic mathematical model to simulate the functioning of a dairy farm, and to evaluate the impact of changes in one or several technical or economic factors on its profitability.

Materials and Methods: The model is fed with data from a dairy farm or using of a randomly generated farm under the specifications defined by the user. The model accounts for heifers, lactating and dry cows (biological model for each group). For each animal, sub models are developed for feeding, diseases, environmental factors, facilities, management, reproductive management, and economics. All these factors follow established equations that account for the complex interactions among them. Default values for variables are provided, but the user can changed them. The conditions established are simulated on an animal-by-animal and day-by-day basis. The outcome provides a list of technical and economic indicators essential for the decision-making process, including demographics, production, reproduction, heifers, diseases and economics. As an example, a 300 adult dairy cow farm (average of 38 L/milking cow/day) with the replacement heifers was used. The farm had an average pregnancy rate of 15%, a milk price of 0.33 euros/L and a labor efficiency 43 cows/person. The question was raised on the suitability of using a time-fixed artificial insemination protocol. The timed-fixed insemination was planned only for the first insemination at 77 DIM, with a 50% fertility for first lactation cows, and 45% fertility for older cows, and a cost of 13 euros per treatment. The model was used to provide the proper data to help in the decision process.

Results: During the 4-year simulation, the application of the fixed-time artificial insemination reduced DIM (from 202 to 181 days) and the proportion of problem cows (not pregnant by 150 DIM; from 14.3 to 8.5 %); and it increased milk production (from 37.4 to 38.6 L/milking cow/day) and the gross margin (from around 54.000 to 70.000 €/year, or from 184 to 236 €/cow/year). The simulation information indicates that for each percentage point improvement in pregnancy rate there is an increase in 4.83 euros in the gross margin per cow. The breakeven point for the use of time fixed artificial insemination was set at a pregnancy rate of 24.2%. The decision was independent of the price of milk over a range of 0.28 to 0.38 €/L or the level of production (tested at 8000 and 15000).

Conclusions: The model provides a powerful and useful tool to explore the medium and long term consequences of changes in technical and economic decisions on the economic sustainability of dairy farms. The program is user friendly, web-based and available in English, Spanish and Catalan (www.dairyfarm.es/simulador).

Resilient Cattle; predicting postpartum disease before drying off

Ingrid Den Uijl ¹, Inge Santman-Berends ², Sanne Carp van Dijken ²,
 Gardien van Schaik ², Theo Lam ² and Weerbaar Vee

¹University of Surrey, Guildford,, United Kingdom, ²GD Animal Health,

Deventer, Netherlands

Objectives: Udder health, fertility and leg problems are of importance in the dairy industry and a long productive life of cows. The immune system is a driving force in the maintenance of a good health status. Immune parameters will be evaluated for their capacity to identify resilient individuals. Previous research showed that innate immunity is associated with disease risks in cows, but it is unknown if the occurrence of future diseases can be predicted based on innate immunity parameters. Therefore, the aim of this study was to investigate whether it is possible to predict postpartum disorders using natural antibody levels (NABs) in dairy cattle.

Materials and Methods: In 29 Dutch dairy herds milk samples were obtained from all lactating cows between April 2012 and April 2013. IgM and IgG levels against Keyhole Limpet Hemocyanin (KLH) were determined using an ELISA test (Greiner®). Nabs for KLH are considered to represent the innate immunity level of the cow. Test-day milking recording data, fertility records, identification and registration data and comprehensive data from livestock disease registration systems were available. Digital disease registration contained cow-level records with the disease and the date it was observed by the farmer. Survival analyses techniques were used to evaluate if NABs in the last available milk sample prior to drying off were associated with the time to occurrence of postpartum disorders in the first 60 days of the subsequent lactation. The following postpartum disorders were considered: retained placenta, (endo)metritis and ketosis.

Results: The best final model included IgM NAb level, difference in IgG NAb levels between two measurements, parity, SCC and postpartum disease in prior lactations. The validation data showed that the model classified 32% of the cows as having a high risk for developing postpartum disorders. Of the cows predicted to be at high risk of postpartum disease, 31% developed a postpartum disorder. Of the cows that were classified as having a low risk, 86.1% did not develop a postpartum disorder. This means that almost 1 in 3 cows predicted to get the disease did actually get postpartum disease. This is comparable to the number of cows with high somatic cell count developing mastitis.

Cows that were classified as high risk by the model had a 2,7 times higher odds (95% CI: 2,2-3,3) for developing a postpartum disorder than low risk cows.

Conclusions: The study showed the possibility to predict postpartum disorders with a model that, amongst other variables, contained NABs in milk samples. The model can be used to inform farmers which cattle have a high risk for developing a postpartum disorder. This may assist farmers to take measures to prevent the disorders from occurring.

Implementation of vaccination strategies on British dairy farms: the importance of the farmer-veterinary surgeon relationship

Imogen Richens ¹, Marnie Brennan ¹, Pru Hobson-West ¹, Wendela Wapenaar ¹

¹University of Nottingham, SB, United Kingdom

Objectives: Vaccine use in the cattle industry appears to be widespread but there is limited published guidance or set protocols for their use.

Veterinary surgeons have been identified as important sources of advice on disease control and vaccination by farmers, as well as being their preferred vaccine provider. However, there is limited research exploring the farmer-veterinary surgeon relationship in the context of vaccination decision-making.

The objective of this study was to explore the farmer-veterinary surgeon relationship in the context of vaccination decision-making.

Materials and Methods: This study is reported following the Consolidated Criteria for Reporting Qualitative Research (COREQ) guidelines. Twenty-four semi-structured interviews were carried out with dairy farmers, and fourteen with veterinary surgeons. The audio recordings were transcribed verbatim by external transcribers. Anonymised transcripts were imported into qualitative data analysis software (NVivo 10, QSR International) for thematic analysis. To assess the robustness of the coding framework a sample of the transcripts were coded independently by a second researcher.

Results: Thematic analysis suggested that both veterinary surgeons and farmers have a positive attitude towards the use of vaccination and have few barriers to its implementation providing there is evidence of a need to do so. Currently in Britain cattle vaccination schedule decision-making is undertaken on an individual farm basis by farmers and their veterinary surgeon. Farmers perceived their veterinary surgeon to have an important role throughout the decision-making process. The advice of veterinary surgeons was trusted. Veterinary surgeons appeared to group farmers into three 'types' of farmer and these groups influence the vet-farmer relationship and communication. There were differences between farmers and veterinary surgeons extending from differences in risk perception to the perceived influence of outside sources. These differences potentially acted as barriers to effective communication and could therefore lead to either vaccines not being implemented or the use of vaccines that were not necessarily required.

Conclusions: A need for methods to increase farmers' awareness of their herd's disease status and solutions to provide more time and resources to enable vets to discuss disease prevention and control with clients was also highlighted by this study.

Comments: The work was funded by AHDB Dairy (www.dairy.ahdb.org.uk) a levy funded, not for profit organisation working on behalf of British dairy farmers and a division of the Agriculture and Horticulture Development Board, the Centre of Evidence-based Veterinary Medicine and the University of Nottingham.

Herd Health Management: Dairy

P02-002-116

Evaluation of heat stress conditions at cow level inside a dairy barn

Laura Schüller¹, Wolfgang Heuwieser¹

¹Clinic of Animal Reproduction, Freie Universität Berlin, Berlin, Germany

Objectives: The precise measurement of climate conditions that cows are exposed to inside a dairy barn is crucial, because already small variations in THI can negatively influence dairy cows.

Besides the housing conditions also the social hierarchy affects the actual experienced heat stress by individual animals because cows actively seek comfortable climate conditions.

The objectives of this study were to examine heat stress conditions

dynamically at cow level, to investigate the relationship to the climate conditions at stationary locations inside a dairy barn and to compare the climate conditions at cow level between primiparous and multiparous cows.

Materials and Methods: The study was conducted on a commercial dairy farm in Sachsen-Anhalt, Germany from May 2014 to July 2014. The herd consisted of 1,200 Holstein dairy cows with an average milk production of 10,147 kg. The barn was positioned in a NE-SW orientation with open ventilation and a mechanical fan-system. Ambient temperature and relative humidity were recorded using EL-USB-2+ data loggers (Lascar electronics, Salisbury, UK) and used to calculate the THI according to the equation reported by the NRC (1971):

$$THI = (1.8 \times AT + 32) - ((0.55 - 0.0055 \times RH) \times (1.8 \times AT - 26)).$$

Days of heat stress were defined as days with a mean THI \geq 72. Stationary climate conditions within the barn were recorded on 2 locations within the milking parlor and on 3 locations within the experimental pen. Climate loggers within the milking parlor were located in the holding area and the rotary parlor. Climate loggers within the experimental pen were secured on an alley position, on a central position, and on a window position located nearby a ventilation opening in the outer wall. Climate conditions at cow level were recorded with climate loggers attached to the collar of the cows within an isolated rubber tube. These climate data were recorded on cohorts of 6 to 10 primiparous and multiparous cows, respectively in 7 replicates for one week each. Multiparous cows were housed inside the experimental pen for a minimum of 3 weeks before each replicate and primiparous cows were transferred to the experimental pen at the first day of each replicate to enforce a subordinate rank in the social hierarchy.

Results: Sixtyone primiparous and 62 multiparous cows were enrolled in the study. A total of 34,657 time values (2 minute intervals) from 52 experimental days was collected. The AT and THI differed significantly between all stationary loggers. The lowest AT and THI was measured at the window logger in the experimental pen and the highest AT and THI was measured at the central logger in the experimental pen. The RH measured at the pen loggers was 4.53% ($P < 0.05$) lower than measured at the milking parlor loggers. The highest RH was measured at the holding area logger and the lowest RH was measured at the window logger in the experimental pen.

The AT measured at the mobile cow loggers was 1.56 °C ($P < 0.05$) higher than measured at the stationary loggers. The THI at the mobile cow loggers was 2.33 THI points ($P < 0.05$) higher than measured at the stationary loggers. Furthermore, the mean daily THI was higher at the mobile cow loggers than at the stationary loggers on all experimental days. Number of days averaging THI \geq 72 were 12.86 percentage points higher measured at mobile cow loggers than at stationary loggers ($n = 427$, $P < 0.05$). There was no significant difference for the AT, RH, and THI between primiparous and multiparous cows.

The THI at the pen loggers was 0.44 THI points ($P < 0.05$) lower when the experimental cow group was located inside the milking parlor. The THI measured at the mobile cow loggers was 1.63 THI points ($P < 0.05$) higher when the experimental cow group was located inside the milking parlor.

Conclusions: Our results indicate, that the actual heat stress experienced of dairy cows differs significantly from the heat stress conditions measured at stationary locations inside the barn and heat and humidity are not eliminated effectively from the cows immediate surrounding. Thus, a wide range of microclimates between different locations as well as between individual cows exists inside a dairy barn. Heat stress is underestimated when climate conditions are obtained from one stationary location inside the barn. For the determination of specific THI thresholds, the climate conditions should be obtained in the immediate surrounding of the cows.

P02-002-117

Swelling at the injection site after Q fever vaccination - an important information

Elisabeth Deckinger¹, Britta Janowitz¹, Benjamin Motsch¹, Michaela Alex¹, Sylvia Keilholz¹, Norbert Meier¹, Jens Boettcher¹

¹Bavarian Animal Health Service, 85586 Poing, Germany

Objectives: The zoonotic pathogen *Coxiella burnetii* (Cb) causes Q fever in humans and Coxiellosis in many species of animals of which ruminants are of major concern. Large quantities of Cb are shed during parturition; additionally, individual cows are shedding Cb with their milk. Since 2010 a vaccine (Coxevac[®], CEVA, Düsseldorf) got registered in Germany. It is an important tool to reduce Cb-shedding. An increased awareness among farmers and veterinarians regarding side effects of vaccination exists, because former vaccines induced unacceptable swellings: The size was sometimes comparable to a loaf of bread.

Materials and Methods: In this study 80 dairy cows and their off-springs in a chronically Cb-infected herd were vaccinated. Before vaccination individual milk samples from each quarter of the udder were analyzed for phase-specific antibodies (Phase I and Phase II-ELISA) and by quantitative PCR. At each vaccination a Li-heparin and a clotted blood sample were collected to assess the Interferon-(IFN)- γ -response (IFN- γ -recall assay) and phase-specific antibody titers, respectively. After vaccination (1-3 days p.v.) the injection site was controlled for swelling (diameter in cm) and the temperature was recorded rectally. Pregnancy was controlled by rectal palpation before and after vaccination. Cows in the last month of pregnancy were vaccinated after calving.

Results: In 11 of 72 cows Cb was detected in milk samples. A variable number of quarters of the udder per animal were affected. 47% of animals showed a palpable swelling after 1st vaccination, and in 16% of animals it even exceeded 5 cm. However, they disappeared without treatment within two weeks. Temperature exceeded 39.5°C in 6.1% of vaccinated animals. No abortion was observed.

After 1st vaccination swellings were significantly associated with positive IFN- γ -results (cut-off 15%) before vaccination. Generally, vaccination resulted in a strong increase of Phase II-titers and IFN- γ -reactivity and only a slight increase of Phase I-titers. However, a weak IFN- γ -response and no side effects after 1st vaccination were observed in cows with elevated phase I-titers and detection of Cb in milk before vaccination (i.e. chronic infection of the udder). Remarkably, strong IFN- γ -reactivity in absence of antibodies characterized the immune response of unvaccinated heifers and calves. It is assumed to be due to an early infection of calves. Thus absence of antibodies should not be misinterpreted as non-immune (i.e. susceptible to infection).

Conclusions: Swelling at the site of vaccination was related to a preexisting immunity. Consequently, farmers and veterinarians are advised to record such swelling per animal; an exclusion of these animals from repeated annual revaccination might be considered. Indeed, prudence is indicated, since "over-vaccination" might become a future problem: Recently very large and persisting swellings were reported in a herd with a repeated annual revaccination.

Milk sampling should include all quarters of the udder! Chronically infected cows need to be identified prior to and controlled after vaccination. Serology is inappropriate to assess immunity in heifers.

Comments: This study was financially supported by the Free State of Bavaria and the Bavarian Joint Founding Scheme for the Control and Eradication of contagious Livestock Diseases.

Herd Health Management: Dairy

P02-002-118

Operating procedures for dairy farms and their servicing veterinary practices- an analysis and optimization of the organization of work processes

Anne Hesse¹, Stefan Borchardt¹, Jan-Marcus Lehmann², Wolfgang Heuwieser¹

¹Clinic of Animal Reproduction, Freie Universität Berlin, ²Hochschule für Technik und Wirtschaft Berlin, Berlin, Germany

Objectives: In contrast to quality assurance programs in industrial companies a similar model in animal and medical science is only starting to develop. Many farmers and veterinarians lack the awareness of quality assurance programs although they have major responsibility in the food chain. Standard operating procedures (SOP) play a major role in quality assurance programs in industrial production. They provide clear instructions so that fluctuations in product quality are reduced.

The objective of this study was to gain insight into the organization of work processes and analyze the current use of standard operating procedures on German dairy farms.

Materials and Methods: In spring 2015, a questionnaire was handed out to 300 German dairy farmers attending 3 continuing education events. It consisted of 10 questions and 9 statements.

In addition to general farm information (e.g. herd size, annual milk yield, number of employees) the participants were asked regarding the use of SOP (e.g., existence of SOP considering different areas and their documentation). Nine questions evaluated statements referring to how employees handle their tasks, to the documentation of work instructions and a potential interest in SOP available through mobile devices.

Results: Overall 96 questionnaires were returned (32%). On average the farms were milking 170 cows with an annual milk yield of 9.600 kg and a bulk tank somatic cell count of 190.000 cells/ml.

Standard operating procedures were used on 91% of the farms, mostly in areas such as feeding, milking and calf rearing. However, only 51% (41/79) had a written version of their work instructions. On 61% (75/94) of the farms identical tasks were performed differently by different employees and 73% (69/95) of the farmers stated that certain tasks were being performed in a different way than intended by the management. During the creation of operating procedures veterinarians were consulted most frequently as external advisors (68%, 52/77). Nearly all of the surveyed farmers (96%, 89/93) were interested in improving certain areas on their farm and 67% (63/94) of the farmers were interested in using prefabricated SOP and adjusting them to their specific needs.

The majority (69%, 63/91) stated that there is not enough continuing education for the workers and 52% (48/93) did not think that creating SOP was difficult.

Conclusions: There is an obvious discrepancy between the motivation of the farmers to improve the performance on their farm and the expertise in realizing these goals and intentions.

The agricultural sector is observing a trend to larger farms with more animals and a higher percentage of seasonal or migrant work forces. Those farms could benefit from the implementation of high quality SOP as these can help to optimize the management by standardizing the work flow and prevent losses in product quality, work quality and labor efficacy.

Herd Health Management: Dairy

P02-002-119

Predicting and preventing disease in dairy herds using a risk analysis model

Richard Sibley¹, Peter Orpin²

¹West Ridge Veterinary Practice, Witheridge, ²Park Vet Group, Leicester, United Kingdom

Objectives: The veterinary profession has traditionally been motivated by a model of test and treat where disease outbreaks are recognised, diagnosed and treated and then preventive action taken to prevent recurrence. More effective prevention programmes can be used to predict disease occurring by measuring and monitoring risks, enabling cost effective disease management programmes to be implemented at a herd level to avoid disease outbreaks or limit the impact of any disease within a herd. This study demonstrates the use of a simple web based risk assessment tool to help veterinarians and farmers predict and prevent common infectious diseases.

Materials and Methods: Over 2000 dairy herds have become engaged in various disease management programmes as part of campaigns of awareness and implementation in the United Kingdom. A herd health management tool (myhealthyherd.com) has been used to measure and manage risks pertinent to the particular disease relevant to the herd on these farms as part of their health management.

Risks of disease entry (biosecurity risks) and risk of disease spread (biocontainment risks) were measured by a system of questions, scores and weightings for Bovine Viral Diarrhoea virus (BVDv), Infectious Bovine Rhinotracheitis (IBR), Mycobacterium Avium Paratuberculosis (Johnes Disease, MAP), Bovine Tuberculosis (bTB), Neospora and Bovine Respiratory Disease (BRD). The algorithm in the model then calculated the relative risks of each of these diseases being a problem to the herd, giving veterinarians relevant information on which to base practical preventative advice to minimise the impact of these diseases to the herd.

Results: 2993 herds have completed risk assessments for one or more of the listed diseases. Most showed high levels of risks of specific diseases entering and spreading within the herd, suggesting a high economic impact should the disease exist or be a threat to the herd. Many of the high risk herds were not infected or affected by the particular disease, yet were at high risk, allowing specific advice to be given on biosecurity and vaccination as a preventative rather than a curative. For example, over 70% of herds were at high risk of BVD entering the herd and causing significant impact to the health of the herd, yet less than 10% were actively infected with many of the uninfected herds taking no significant precautions to prevent disease.

There were major geographical differences, particularly related to risks such as stock densities and cattle movements, making some areas much higher risk to disease than others. For example, in some areas, over 76% of herds introduced cattle into their herds without any form of quarantine, and over 50% had cattle drinking from water courses that has passed through other cattle farms.

Conclusions: Many dairy farms are at high risk of infectious disease entering and spreading within their herds, causing significant impact on the health of the herd. Traditionally, many farmers and veterinarians wait for disease to become established and then take action to control and eradicate the disease. This study demonstrates that disease risks can be used to predict and prevent many common infectious diseases entering and spreading in herds thus allowing practical and effective measures to be taken to prevent diseases before they become established.

Herd Health Management: Dairy

P02-002-120

Dairy data quality, much more than just missing data.

Kristof Hermans¹, Geert Opsomer¹, Bonifacius VanRanst¹, Jenne De Koster¹, Mieke Van Eetvelde¹, Sander Moerman¹, Hannes Bogaert¹, Elke Depreester¹, Jan Vandepitte¹, Osvaldo Pascottini¹, Miel Hostens¹

¹Faculty of Veterinary Medicine, Department of Reproduction, Obstetrics and Herd Health., University of Ghent, Merelbeke, Belgium

Objectives: Data stored in dairy herd management software could be used by veterinarians for herd health management. Data ought to be of high quality in order to be useful. Analysing data of poor quality will result in erroneous management decisions. For most researchers and veterinarians data quality equals missing data. Data quality however, is acknowledged to be a multidimensional concept. For instance, the recording of milk production data after a dry off event is considered to be a relational constrain violation and has nothing to do with missing data. We aimed to raise awareness regarding data quality being more than a complete dataset.

Materials and Methods: For all herds connected to dairy data warehouse, the database of the herd management software was extracted via an automated tool. The automated extraction tool and procedure are developed and owned by the company Dairy Data Warehouse (DDW) ©. All animals, active and historic, male and female, from the extracted dataset were queried for the following data anomalies: the existence of events prior to the date of birth; the recording of events with a date in the future; the registration of a male animal producing milk; the recording of multiple death events for the same animal and the recording of a negative milk production amount. Errors were logged on animal level and loaded into an excel file. If the same data error occurred multiple times in the same animal, it was only counted for as one.

Results: In total 1,235,279 animals from 333 different dairy herds were extracted. All 5 anomalies were detected. Three percent or 37,264 animals had anomalies in their data. In total 40,822 anomaly cases in 205 different herds were detected. With 61.1%, the error, events prior to the birthdate was the most registered. Negative milk production was the second most important data fault, with 37.2%. In 1.1% of the anomalies an event happened in the future. Male animals producing milk and the recording of multiple death events happened respectively in 0.4% and 0.3% of the recorded cases. The median herd data anomaly rate was 0.1%, defined as the number of animals within a herd with a data anomaly divided by the total number of animals included in the herd database. The maximum herd data anomaly rate was 86.5%. The minimum herd data anomaly rate was 0%.

Conclusions: None of the queried data errors are linked to missing data. Compared to literature, only a low percentage of animals had data errors. This can be explained by the low amount of tested data errors. When more anomalies will be defined and queried, the percentage of animals with a data anomaly will probably increase. All data from animals with events recorded prior to the birthday, is compromised. Hence, the data cannot be used for herd health management. A clear difference in herd data anomaly rate between herds is observed. The reason whether the latter is related to the used software or explicit herd management factors has to be investigated.

Herd Health Management: Dairy

P02-002-121

Link between the histology and endocrine functioning of the pancreas in overconditioned dairy cows at the end of pregnancy

Hannes Bogaert¹, Jenne De Koster¹, Wim Van den Broeck², Geert Opsomer¹

¹Department of Reproduction, Obstetrics and Herd Health,
²Department of Morphology, Faculty of Veterinary Medicine, Ghent University, Merelbeke, Belgium

Objectives: Overconditioning in dairy cows, like obesity in humans, appears to be an important risk factor to develop a wide variety of health problems in the periparturient period. Since the endocrine pancreas plays a central role in the metabolic adaptations at the start of lactation, maladaptations that go along with overconditioning may play a pivotal role in the occurrence of major health disorders. The objective of the present study was to determine the effects of overconditioning at the end of pregnancy on the histology of the pancreas and the functioning of the pancreatic β cells in dairy cattle.

Materials and Methods: Ten pregnant Holstein Friesian cows were selected based on body condition score (BCS) and divided in 2 groups: normally- (≤ 3.5) and overconditioned (> 3.5). During dry period, animals were weekly monitored for BCS and back fat thickness (BFT), and blood samples were taken to determine the non-esterified fatty acid (NEFA) concentration. At an average gestation period of 260 days, cows underwent an intravenous glucose tolerance test (IVGTT) to measure the insulin secretory capacity of the pancreas. A glucose bolus was administered IV and blood samples were taken on different time points to determine glucose and insulin concentrations. Cows were euthanized on average 8 days after the IVGTT, after which 15 pancreatic tissue samples were taken by systematic random sampling. Using a standard protocol, hematoxylin and eosin (HE) stained sections were prepared from the tissue samples. Based on data obtained from the HE stained sections and the IVGTT, macroscopic, histological and functional parameters of the pancreas were determined. Data were statistically analyzed using SAS software. Normality of the data was checked using the Kolmogorov-Smirnov test. To assess the differences between the 2 groups, the PROC ANOVA function and the PROC NPAR1WAY function for resp. normally and not-normally distributed variables were used. Pearson correlation coefficients (r) were calculated between variables representing the pancreatic characteristics and the cow characteristics (BCS, BFT and NEFA level). Significance* and tendency (t) were declared at $P < 0.05$ and $0.05 < P < 0.1$, respectively.

Results: Histological results revealed that overconditioning at the end of pregnancy comes together with fat infiltration in the pancreas and this was accompanied by a relative increase in the amount of endocrine tissue (pancreatic fat%*: 1.29 ± 1.43 ; 6.75 ± 7.11 ; islet%*: 1.28 ± 0.13 ; 1.73 ± 0.15 ; #islets per surface area pancreas (t): 1.74 ± 0.12 ; 2.15 ± 0.37 for the normally- and overconditioned group resp.). In addition, results revealed a positive correlation between the peripheral NEFA concentration and the pancreatic islet percentage ($r = 76^*$) and the number of islets per surface area pancreas ($r = 0.83^*$). The results of the IVGTT revealed that overconditioned animals had a higher insulin secretory capacity of the endocrine pancreas. The peak insulin concentration, the area under the curve (AUC) for insulin for the different time intervals and the acute insulin response to glucose (AIRg) after the administration of the glucose bolus, all tended to be higher in overconditioned cows. In addition, the peak insulin concentration was correlated with the peripheral NEFA concentration ($r = 0.63^*$). No significant effects of the condition or lipid metabolism on the elimination rates of insulin (ER_{ins}) and glucose (ER_{glu}) were found.

Conclusions: It can be concluded that overconditioning at the end of pregnancy in dairy cattle, as obesity in humans, is accompanied by an increase of fat tissue and a concomitant relative increase in endocrine mass in the pancreas, finally leading to an increased activity of the endocrine pancreas. Further research is however warranted to understand the underlying mechanisms with regard to the increased sensitivity towards disease in order to come to more successful preventive strategies and curative treatments.

P02-002-122

Mastitis detection in modern free-stall barns with conventional parlour milking and automatic milking

Mari Hovinen¹, Timo Hurme², Kristiina Sarjokari¹, Marianna Norring¹, Leena Seppä-Lassila¹, Timo Soveri¹

¹University of Helsinki, Helsinki, ²MTT Agrifood Research, Jokioinen, Finland

Objectives: Udder health of every individual cow has been well known by the farmers in traditional small tie-stall barns of the Nordic countries. Has this tradition changed after converting to larger farms? Objective of the study was to explore udder health management in modern, large free-stall barns.

Materials and Methods: We studied 82 free-stall dairy farms with an average herd size of 126 cows with conventional parlour milking (50 farms) and automatic milking (32 farms) in Finland in 2012. In an interview, farmers had to select the methods of detecting mastitis used in their farm from a list of 12 choices including a choice "other, describe". Herd health recordings of cow somatic cell count (SCC) and records of quarter milk bacterial analysis were also used to check the reliability of the data inquired. This was a part of a larger study exploring the associations between animal health and grouping of cows.

Results: Eighty-two and 72% of the farms with conventional and automatic milking used test-day cow SCC records and CMT-test to detect mastitis. In conventional milking 94% of the farms checked visual appearance of milk and 64% palpated the udder during milking. In automatic milking 84% of the farms used electrical conductivity and 59% automatic milk colour evaluation. They also monitored milking frequency (69%) and unsuccessful milkings of the cows (56%) in order to detect mastitis. Other choices were used in less than 30% of the farms. Over 90% of all farms used bacterial sampling of a quarter to decide whether to treat or dry it or cull or follow-up the cow. Farmers milking cows automatically used broader spectrum of detection methods in many different combinations.

Conclusions: In conclusion, farmers use a wide range of methods to detect mastitis in modern dairy farms studied. Decisions to treat or not treat a cow with mastitis are based on information of the inflammation status of the udder and on the interpretation of the causative bacteria. These final decisions are made by a veterinarian according to the legislation. Adequate diagnosis, treatment and prognosis are important in order to reduce the consumption of antibiotics and also from animal welfare and economic perspective.

Herd Health Management: Dairy

P02-002-123

Assessment of transition cow management on six UK dairy farms using apps to assess farm management, disease incidence and disease costs

Paddy Gordon^{1,*}¹Shepton Veterinary Group, Shepton Mallet, United Kingdom

Objectives: The transition period represents a key time in the dairy cow production cycle, with the outcome having a major impact on health, welfare, production and profitability. The aim was to assess transition cow management and outcomes on six UK dairy farms using novel 'apps' called the Risk Assessment Tool (RAT) and Economic Assessment Tool (EAT) (Elanco Knowledge Solutions ; Elanco Animal Health).

Materials and Methods: Farms received two visits from the author, an experienced dairy vet, at an interval of four months. A structured farm walk was conducted with details entered onto the RAT app, using an iPad. The app requires assessment of management, nutrition and environment to identify key areas where inputs are sub-optimal.

Transition disease levels were assessed from farm records, vet invoices and interviewing the farmer. In addition freshly calved cows were screened for ketosis using milk samples (Keto-test, Elanco Animal Health). The data was used to populate the Economic Assessment Tool to identify management inputs (routine treatments), disease levels and the financial impact of transition period outcomes.

Results: Vet assessment using the RAT identified risk factors for cow health during the far-off, transition and fresh calved periods. The app helped to prioritise the changes needed to achieve the maximum impact. The most common areas for advice were on management and nutrition. Mastitis and metritis had the greatest financial impact, and most herds had underlying ketosis. Identification and recording of the key disease area were used to monitor and to raise awareness on farm. Reassessment four months later found improvement in health and financial performance of £19 per cow calving event, through reduction in disease. The cost of the transition period (investment and disease outcomes) averaged £171 per cow. This was typically £40 in investment (routine treatments and supplements), and the remainder and major cost was disease outcomes.

Conclusions: Transition period management is an area where dairy vets can deliver improved health and profitability. The apps developed provided a structured method for assessing transition period management and outcomes. Many of the areas identified for change involved people and nutrition, and so barriers could be overcome without significant capital expenditure. Change advised proved to be effective in reducing disease and improving the farm financial position.

Comments: Further data will be added showing individual farm outcomes and statistics if abstract accepted.

Mycoplasma bovis Seroprevalence in Healthy Dairy Cattle in Turkey

Mehmet Ozden^{1,*}Cem Keskindil²¹Bacteriology, Izmir Bornova Veterinary Control Institute, Izmir,²Marketing and Technical Services, Bayer, Istanbul, Turkey

Objectives: *M. bovis* in cattle exacerbates the respiratory disease. In 128 BRD outbreaks in France and Germany, *M. bovis* was isolated combined with *M. haemolytica* and / or other bacteria. This pathogen has been considered a silent one, but increasing the damage in the respiratory tract and promoting relapses of BRD. In Turkey, the role of this pathogen is not completely known. The objective of this study was to determine the sero-prevalence of *M. bovis* in sera of healthy animals.

Materials and Methods: Blood samples from animals collected from different regions in the seven provinces of Aegean area (Izmir, Manisa, Aydin, Mugla, Usak, Kutahya, and Denizli provinces). Sera samples were taken for routine analysis for Brucellosis monitoring from certified dairy farms. These farms are free from tuberculosis too. Some of these cattle had imported from different countries. A total of 624 blood samples, coming from 21 different farms were analyzed by ELISA test (Bio-X Diagnostics) and results were calculated according to manufacturer's manual.

Results: Eventually 24% of sera were evaluated as positive. Positive results shown different ratios between different farms. These animals belong to the west region provinces of Turkey. All farms were intensive dairy facilities. These results have shown a high frequency of seropositive animals considering that they are healthy and well-fed. These farms could describe "good managing and feeding" farms to rest of other farms. Farmers and breeders prefer to buy these cattle in spite of high prices primarily because of healthy conditions.

Conclusions: *M. bovis* infections point out high ratio of sera positive results, because of that, these infections must be considered in mastitis and BRD infections. Further studies with PCR in milk or from BRD affected animals would give a better understanding of the distribution of *M. bovis* in Turkey.

Herd Health Management: Dairy

P02-002-125

Differences in neck movements associated with rumination recorded by accelerometers affixed to neckbands in different dairy cattle herds

Takashi Sato¹Yasushi Chida^{2,*}Yoshitaka Deguchi³Toshihiko Takahashi⁴Shigeru Sato¹Keiji Okada¹¹Department of Veterinary Medicine, Iwate University, Morioka, ²FRONT, Konan University & Bycen Inc., Kobe, ³Department of Animal Science, Iwate University, Morioka, ⁴Department of Sustainable Agriculture, Rakuno Gakuen University, Ebetsu, Japan

Objectives: Our research group succeeded in obtaining wireless recordings of neck movements associated with rumination in dairy cows using a three-dimensional accelerometer attached to a neckband. Rumination behavior in cows is essentially a physiological response associated with digestion and is strongly correlated with feeding and milk production. However, accurately monitoring the temporal characteristics associated with rumination behavior for clinically and herd health assessments in individual herds is difficult. This study compared rumination data, herd characteristics (e.g., milk production) and environment on three different farms.

Materials and Methods: Twenty-four Holstein cows in free-stall barns

on three different farms (A, B and C) in the Kushiro area of Hokkaido were used in this study. Wireless 3-axis accelerometers affixed to commercial neckbands were used to record neck movement data in ruminating cows. These data were automatically transferred and stored on a data server over a local wireless network (WiSUN, IEEE802.15.4g) and the internet. Cow behavior was simultaneously recorded on digital video in order to correlate the obtained acceleration data with cow movements. The sampling frequency of the accelerometers was set to 20 Hz and the length of each stored dataset was 1024 points. In order to compare the differences among farms, the collected data were compiled and analyzed using Excel (Microsoft) and MatLab (MathWorks Inc.). Analysis methods were used autocorrelation and histogram in each direction data, and 3-direction resultant vector and difference of 3-direction resultant vector. The Penn State Particle Separator (PSPS) was used to quantitatively determine the total mixed ration (TMR) in each farm. On each farm, products information and information of oral interview were also collected in experimental cows. The data obtained from the three farms were compared using ANOVA. This study was approved by the Animal Research Committee of the Faculty of Agriculture at Iwate University, Japan. Experiments were conducted according to the Iwate University Guidelines for Animal Experimentation.

Results: The acceleration waveforms obtained during rumination were markedly different among farms A, B and C. After calculating the autocorrelation function, the amplitudes of left-right and up-down movements for cows on farm C were significantly higher than those for cows on the other farms ($p < 0.01$). For cows on farm C, the interval between peaks of head movement has a strong tendency to change periodicity pattern. The granularity of the TMR for each farm was as follows: < 1.7 mm, A: 32.4%, B: 17.3% and C: 18.6%; 1.7 to 8.0 mm, A: 61.8%, B: 43.1% and C: 39.9%; 8.0 to 19.0 mm, A: 5.8%, B: 30.4% and C: 36.5%; > 19.0 mm, A: 0.0%, B: 9.2% and C: 5.0%. The average milk yield was 25.6 ± 1.6 kg/day on farm A, 24.7 ± 2.4 kg/day on farm B, and 31.1 ± 1.6 kg/day on farm C. The sufficiency ratios of the cattle beds on each farm were 71% on farm A, 76% on farm B, and 106% on farm C ($p < 0.05$).

Conclusions: Rumination is a physiological reflex with chewing. However, no studies have demonstrated that the movements associated with chewing are affected and related by rumination. In this study, differences in rumination behavior (inferred based on accelerometer and video data) were observed among cows on different farms. It is considered that these differences were due to the granularity of the TMR contents and environmental factors between farms. Furthermore, the periodic and greater amplitude of acceleration during rumination may also related with farmer's productivity and environmentally appropriate.

P02-002-126

Serum protein profile of Holstein cows during the transition period

Juliana F. dos Reis¹Karina M. Madureira²Cynthia P. Costa e Silva¹Vinicius Baldacim¹José J. Fagliari³Viviani Gomes^{1*}

¹University of São Paulo, São Paulo, ²Federal University of Bahia, Salvador, ³UNESP, Jaboticabal, Brazil

Objectives: The transition period is characterized by metabolic adaptations in order to supply the energy demands at the end of pregnancy. In this context, the use of biomarkers such as serum proteins promotes a multifunctional profile and evaluation of inflammatory and

immunological condition of cows during this period. The aim of this study was to evaluate longitudinally the serum protein profile during the transition period in Holstein cows bred in Brazil.

Materials and Methods: Thirteen pregnant cows were evaluated, from second to fourth lactation. Data of the occurrence of disease during the study period were obtained by consulting the farm records. At the time of sample collection, it was also evaluated the body condition score (BCS). Blood samples ($n=78$) were taken weekly, from the second week before calving (-2) to the third week in milk (+3) including calving (0), for determination of serum protein profile, consisted by determination of total serum protein (TSP); negative acute phase protein (albumin - ALB and transferrin - TF); positive acute phase protein (haptoglobin - HP; acid glycoprotein - AG and ceruloplasmin - CP), and also the heavy and the light chain of IgG and IgA, by SDS-PAGE electrophoresis.

Results: PT values decreased gradually ($P=0.000$) from 6.4 g/dL in week -2, to 6.2 g/dL at calving (0), increasing in subsequent moments ($+3=7.3$ g/dL). The concentrations of the heavy chain ($-2=919.4$; $-1=1074.5$ mg/dL) and the light chain of IgG ($-2=393.9$; $-1=466.7$ mg/dL) were lower before calving compared to postpartum ($+1=1,283.3$; $+2=1,374.2$ and $+3=1,630.3$ for the heavy chain and $+1=463.4$; $+2=573.7$ and $+3=651.8$ for the light chain). For IgA the values decreased ($P=0.001$), from 51.9 mg/dL (-2) to 34.0 mg/dL (+1), and increased in +2 (45.4 g/dL) and +3 (62.6 g/dL). The values of HP and CP increased ($P=0,000$) from -2 (HP=16.6 mg/dL; CP=8.6 mg/dL) to +3 (HP=60.9 mg/dL; CP=127.1 mg/dl). ALB showed slight variations during the transition period ($P=0.000$), while the TF ($P=0.101$) and AG ($P=0.105$) were stable. For the BCS it was observed difference ($P=0.003$) between -2 (ECC=4.0) and +1 (ECC=3.0). It was reported the occurrence of dystocia (4/13), retained placenta (1/13) and hypocalcemia (1/13) on the day of calving (0) and uterine infections (5/13) and ketosis (1/13) occurred in the postpartum. The lowest values of total proteins and immunoglobulins (Igs) obtained before calving is related to colostrum development or, in the case of Igs, to reduction in the amount and function of B lymphocytes, which may cause immunosuppression. Increasing concentrations of positive acute phase proteins around calving can be explained by the increase of their synthesis after liver stimulation induced by pro-inflammatory cytokines during calving. In contrast, negative acute phase proteins were inhibited.

Conclusions: In conclusion, these factors linked to the high BCS before calving and abrupt lost weight after calving probably might have caused accentuated metabolic and immunological changes during the transition period, increasing the susceptibility of cows to bacterial infections from the first week after calving.

Herd Health Management: Dairy

P02-002-127

Subclinical ketosis testing as a part of herd health management

Kristiina Sarjokari^{1*}Eeva Mustonen¹Johanna Sillanpää¹Timo Soveri¹

¹Department of Production Animal Medicine, University of Helsinki, Faculty of Veterinary Medicine, Saarentaus, Finland

Objectives: Subclinical ketosis reduces milk yield and impairs fertility and immunity of dairy cows. Objectives of this study are to 1) test suitable subclinical ketosis tests and different testing protocols as tools for herd health management, to 2) evaluate the value of routine tests of milk acetone and BHB for farmers and veterinarians, to 3) explore the incidence of subclinical ketosis in Finnish dairy herds, and to 4) compare the ketosis risks between Holstein and Ayrshire cows.

Materials and Methods: In Finland, 6000 dairy herds DHI samples were checked for milk acetone and BHB with FOSS MilkoScan™ FT+/6000 for three months, during October to December 2015. Among those herds, 20 herds were selected for additional weekly milk sampling, and two herds for additional clinical examination and blood sampling of the cows that were at the greatest risk for subclinical and clinical ketosis.

Two high-producing dairy farms were visited once a month for three months. During the farm visit, dairy cows between 5–50 days postpartum were examined. Together with full clinical examination, urine, milk and blood samples were taken for analysis. Cow-side tools used were Keto-test BHB (β-hydroxybutyrate) dipsticks, Ketocheck powder and BHB-check analyzer. Serum samples were used to analyse non esterified fatty acids, BHB, cholesterol and triglycerides.

The incidence and prevalence of subclinical ketosis will be measured with the different tests, and sampling frequencies used in this study. The association between subclinical ketosis and breed of the cow will be modelled with a logistic mixed model, with herd as a random effect. Herd and cow data are gathered Finnish national dairy herd recording database, operated by ProAgria Agricultural Data Processing Centre.

Results: The results will be available by the time of the congress, because the cow-side and laboratory analyses will continue until the end of December 2015. We will present a way to utilize subclinical ketosis testing as a part of herd health management planning routines of the farmer and his veterinarian. The value of the different tests and sampling routines explored will be compared and described. The incidence on subclinical ketosis in our study population will be presented, including the comparison of the incidence risks of Holstein and Ayrshire cows.

Conclusions: Testing the cows for subclinical ketosis is useful in evaluating the feeding, housing and management of high producing dairy cows. More in depth protocols for comprehensive herd health management are needed, and should be further developed.

Prevalence of subclinical ketosis monitored by a semiquantitative cow-side milk beta-hydroxy-butyrate test in Hungarian dairy herds

Laszlo Konyves¹ Peter Kovacs¹ Attila Repasi² Janos Bartyik³ Endre Brydl¹ Norbert Solymosi¹ Peter Hejel⁴

¹Department of Animal Hygiene Herd Health and Veterinary Ethology, Szent Istvan University, Faculty of Veterinary Science, Budapest, ²Dozsa Agricultural Co, Kenezlo, ³Enyingi Agrar Co., Matyasdomb-Agostonpuszta, ⁴Vet-Produkt Ltd., Babolna, Hungary

Objectives: The objective of the study was to examine the prevalence of subclinical ketosis (SK) manifested in ketolactia in Hungarian large-scale dairy herds. Further aim was to analyse the relationship between some cow-related and management factors, the different clinical diseases and the SK.

Materials and Methods: 491 Holstein Friesian dairy cows in <35 days in milking kept in eight different large scale dairy farms in Hungary were involved in the study. The examinations regarding the concentration of beta-hydroxy-butyrate (BHB) of the milk were conducted on-site, from milk samples, using a colorimetric semi-quantitative test (Keto-Test™). Data of each of the cow- and management related factors (number of lactations, previous lactation production, number of milked cows, housing technology) and clinical diseases (retained placenta, metritis,

mastitis, abomasum displacement, diarrhoea, lameness) were recorded. The relationship between the different variables were analysed by generalized estimating equations statistical model.

Results: Different severity of SK (≥100 μMol/L milk BHB) was diagnosed in 38% of the animals examined. SK prevalence showed a significant variance in the eight examined dairy herds (25-57%). The probability of SK with increasing number of lactations showed a non-significantly rising tendency. The milk production of the previous lactation and the size of the herd did not show significant relationship with the odds of SK. In the case of cows suffering from various diseases the concurrent presence of SK was diagnosed with high prevalence (>50% on average).

Conclusions: Although the prevalence of SK is remarkably high in Hungarian dairy herds, a significant variance was detected in the eight examined farms. The parallel onset of clinical diseases and SK was found in a high rate. The implementation of the Keto-Test™ colorimetric semiquantitative milk BHB cow-side test is a useful tool for monitoring ketosis in dairy herds. The diagnosis of SK may indicate the higher risk of other clinical diseases in the periparturient period in dairy cows.

Comments: The authors express thanks to Elanco Animal Health and Vet-Produkt Ltd. for the material and logistic support of this study.

Understanding the irrational dairy farmer - a study into farmers' decision making

Erling Kristensen¹ Esben Jakobsen²

¹Heden & Fjorden, Herning, ²Arla Foods, Viby, Denmark

Objectives: In WBC Chile 2010 we presented a set of research-based recommendations to bridge the gap between science and practice in dairy herd health management.¹ Now, with cow-mortality as an example, we offer insight into our approach method from a larger field study.

Materials and Methods: We described the theory and methods in 2011². Lately, we have found additional inspiration in the concept of Motivational Interviewing³ and the paper by van der Leek.⁴

We studied 12 very different dairy herds with cow-mortality risk exceeding 10 % per lactation. However, the true study-objective was the interaction between farmer, veterinarian and nutritionist - not cow-mortality per se. We acted as neutral observers to identify and prioritize possible causes of high cow-mortality.

First, participants were presented with a list of possible general causes of cow-mortality at herd level (e.g. lameness, farming skills, poor advisor, stable, staff, lack of faith in own abilities). Second, we asked each participant to identify and rank the three causes of high cow-mortality in this particular herd they judged most important. Third, participants discussed their choices to reach a shared understanding. Next, we presented an estimate of the financial gain related to a 50 percent reduction of cow-mortality. Finally, the participants attempted to agree on a herd-specific action plan to reduce cow-mortality.

We studied the choices and arguments made by the participants, individually and in the group, and compared them to our own interpretation of the situation. Also, we estimated the participants' combined motivation to succeed, their professional knowledge and their level commitment to implement the action plans. Further, all farms were visited in the middle and at the end of the study to learn from the farmer's perception of failure or success.

Results: Obviously, results must be interpreted and understood within the context of each farm. Across herds there was no obvious effect on cow-mortality and no obvious relation between estimated financial gain and observed motivation or level of commitment. Three examples follow as illustration:

Example #1: Participants shared the perception that high cow-mortality was related to lameness in the herd. Consequently, the farmer changed floor type. Now, participants are waiting for cow-mortality to decrease. We would have preferred a validation of the evidence before such an expensive intervention. We still follow this farm because we believe that the participants' poor understanding of causality lead them to un-justified conclusions.

Conclusions: We conclude, that 1) farm-level professional knowledge often was insufficient; 2) herd health advisors must learn how to motivate change; 3) level of commitment was unclear; 4) profit is not (always) a driver. If veterinarians want to qualify themselves to be trustworthy dairy herd health management consultants in the future, these issues must be addressed. Consequently, farmers are not to be perceived as irrational if they do not follow the advice presented by a herd health advisor. Actually, some skepticism towards recommendations seems to be justified.

Comments: ¹ Kristensen & Jakobsen, EL, EB, 2010. (E-)Valuation of Dairy Herd Health Management. Abstract from WBC Chile, pp. 53-64

⁴ van der Leek, M. Beyond traditional dairy veterinary services: 'It's not just about the cows!'. JSAVA, 86; doi: 10.4102/jsava.v86i1.1221

received a tube with internal sealing the base of bismuth subnitrate via intramammary. We evaluated the serum fibrinogen, albumin, total protein, beta hydroxybutyrate, nonesterified fatty acids, insulin, glyco-
 cose, total cholesterol, highdensity lipoprotein (HDL), lowdensity lipo-
 protein (LDL) and triglycerides levels, the sample were collected at six
 moments, namely, M1, at the time of drying (60 days before delivery),
 M2 on the day of delivery, M3 3 days post calving, M4 seven days, M5
 10 days, M6 21 days and M7 with 30 days post partum.

Results: The serum fibrinogen levels, an indicator of inflammatory dis-
 ease, were correlated with HDL ($r = 0.21$; $P = 0.03$) and total protein
 ($r = 0.24$; $P = 0.015$) levels. The serum albumin levels were related to
 tryglycerides ($r = 0.25$; $P = 0.012$) and cholesterol ($r = 0.32$; $P = 0.001$)
 levels. The serum total protein levels were associated with an increase
 of insulin ($r = 0.25$; $P = 0.017$); triglycerides ($r = 0.36$; $P = 0.0002$), total
 cholesterol ($r = 0.22$; $P = 0.03$), LDL ($r = 0.28$; $P = 0.0046$) and HDL ($r =$
 0.34 ; $P = 0.0005$) levels. Furthermore, the insulin levels were related
 to glyco-
 cose ($r = 0.32$; $P = 0.002$), tryglycerides ($r = 0.29$; $P = 0.005$), and
 BHB ($r = 0.22$; $P = 0.04$) levels. The NEFA levels were correlated with
 BHB ($r = 0.62$; $P < 0.0001$) and LDL ($r = 0.27$; $P = 0.007$) levels. The
 tryglycerides levels were associated with BHB ($r = 0.27$; $P = 0.008$)
 and glyco-
 cose ($r = 0.36$; $P = 0.0002$) levels. Finally, the cholesterol levels
 were correlated with HDL fraction cholesterol ($r = 0.47$; $P < 0.0001$)
 levels.

Conclusions: We conclude that, metabolic changes associated with
 energy imbalance and fat mobilization was related to alterations in pro-
 tein metabolism, and probably with immune dysfunction, and suscep-
 tibility to diseases.

Comments: In face of, we believe that this approach has the potential
 to provide new diagnostic and decision support tools to improve ani-
 mal health, whilst simultaneously maintaining optimal production and
 efficiency.

Bovine herpesvirus 5 (BoHV5) subtype b is unexpectedly a recombinant virus between BoHV5 and BoHV1, the agent of infectious bovine rhinotracheitis

Silvina S. Maidana^{1,2,3}Axel Mauroy⁴Etienne Thiry⁴Sonia A. Romera^{1,2,3,5}

¹Consejo Nacional de Investigaciones Científicas y Tecnológicas (CONICET), Buenos Aires, ²Instituto de Virología, Centro de Investigaciones en Ciencias veterinarias y Agronómicas (CICVyA), Instituto de tecnología Agropecuaria (INTA), Castelar, ³Cátedra de Inmunogenética, Facultad de Ciencias Exactas, Químicas y Naturales, Universidad de Morón, Buenos Aires, Argentina, ⁴Veterinary Virology and Animal Viral Diseases, FARAH Center, Faculty of Veterinary Medicine, University of Liège, Liège, Belgium, ⁵Cátedra de Inmunología, Universidad del Salvador, Pilar, Argentina

Objectives: Bovine herpesvirus 5 (BoHV5) is the agent of bovine encephalitis occurring especially in South America, together with BoHV1, responsible for infectious bovine rhinotracheitis (IBR). Among the 3 BoHV5 subtypes, subtype 'b' was until now only detected in Argentina, and seems to be less prevalent. Both BoHV1 and BoHV5 belong to ruminant alphaherpesviruses and share a high genetic similarity. Under experimental conditions, we obtained interspecies recombinants between the involved viruses, BoHV1 and BoHV5. We report here for the first time the identification of homologous recombination between BoHV1 and BoHV5 in field virus isolates.

Materials and Methods: Two fragments of the three BoHV5b isolates were amplified by PCR, then sequenced and a phylogenetic inference was performed using the MEGA version 4 software package. Tree topology was constructed by maximum composite likelihood method with the Tamura and Nei model (1000 replicate bootstrap values). After we amplified by PCR the complete UL27 gene of three BoHV5b isolates, sequenced and genetic recombination was analysed using a sliding-window genetic diversity plot (Simplot software version 3.5.1 available at <http://sray.med.som.jhmi.edu/SCRsoftware>) and the Recombinant Detection Program (RDP), version 3, available at <http://darwin.uvigo.es/rdp/rdp.html>).

Results: We showed by phylogenetic analyses that these three BoHV5b isolates clustered differently with BoHV1 and BoHV5 depending on the genes encoding glycoprotein B (gB) or D (gD) suggesting that these viruses could be recombinants between BoHV1 and BoHV5. We detected two recombination breakpoints located in the long unit (UL) genomic region within the UL27 gene open reading frame. Based on the BoHV5 UL27 gene (GenBank accession number YP003662497.1) one recombination breakpoint extended from the nucleotide (nt) 475 to nt 491 and the other one from 2749 nt to 2761 nt giving a recombination fragment of 2286 base pairs showing 100% nucleotidic identity with the BoHV1.2b subtype genome. Other genomic regions, encompassing five gene fragments from UL and two from the short unit (US) region, were also analyzed by PCR and sequencing, resulting in 100% nucleotide identity with the subtype BoHV5a genome.

Conclusions: Homologous recombination between two related ruminant alphaherpesviruses was shown in natural field conditions. We found three recombinant field isolates between BoHV1 and BoHV5, previously known as BoHV5b subtype. The existence of natural recombination and also the co-circulation of different ruminant alphaherpesviruses increase the complexity to carry on programs of control and eradication of IBR. Especially their impact on BoHV1 differential diagnosis methods and the risk to escape vaccine-induced immunity depending on the degree of antigenic variation caused by recombination should now be taken into account.

IBR

P02-002-227

A new diagnostic approach to serological surveillance of IBR marker vaccinated dairy herds in Cuneo province: a field study

Elvira Muratore¹Barbara Colitti¹Elena Careddu²Chiara Nogarol¹Luigi Bertolotti¹Margherita Profiti¹Adreino Ponzio³Roberto Facelli⁴Sergio Rosati¹

¹Dipartimento di Scienze Veterinarie - Università di Torino, Grugliasco, TO, ²IZSPV, Torino, ³ASL CN1, ⁴Associazione Provinciale Allevatori, Cuneo, TO, Italy

Objectives: In Italy, control measures have been implemented in order to reduce the economic losses caused by Bovine Herpesvirus 1 infection. Since 2004 an eradication programme is in place in Piedmont region. In order to contain the costs of IBR surveillance, the use of bulk milk, has to be considered as a possible diagnostic solution. The recent introduction of an indirect gE ELISA using milk IgG sequential precipitation (Eradikit® BMSK Plus, In3diagnostic) seems a promising tool for IBR surveillance of vaccinated herds. The method was applied to pooled milk samples in dairy herds and compared with individual serum assay over a 12 months period.

Materials and Methods: Three hundred dairy farms of Cuneo province, comprising 28000 lactating cows, were enrolled in this study. Individual serum samples were collected and tested by whole virus and gE blocking ELISAs, and sanitary status updated as follows: 158 gE negative and 142 positive herds. Individual milk samples were monthly collected by breeder association according to periodical milk parameter determination and were used to make milk pools (n=1365 pools in two sessions) of up to 40 lactating cows (median 34, IQR 30-37). Therefore, considering the outcomes of the official test in serum samples, the within-pooled milk prevalence was calculated and the field sensitivity of the method was assessed. Pool samples were processed for IgG concentration and indirect ELISA procedure, according to manufacturer protocol. The results of the first two sessions of analyses are reported below.

Results: All pools from gE negative farms scored negative to Eradikit® BMSK-plus (specificity: 100%, 95%CI: 97.7%>100%). Among positive farms, all but 2 (n=69) having IBR prevalence of lactating cows greater than 2.5% scored positive, while dairy herds having IBR prevalence lower than 2.5% scored negative in all pools. In the latter farms gE positive serum samples were mainly attributable to old vaccinated animals. In one occasion a previously classified gE negative farm turned positive during the serological annual control. Pooled milk test, carried out in two occasions before the annual control, readily detect viral circulation.

Conclusions: Field specificity and sensitivity of Eradikit® BMSK-plus seems adequate for surveillance of gE negative herds and for detection of viral circulation at prevalence level greater than 2,5%. However, during the late stage of eradication, the proposed method would require reduced pool size to detect a weak positive (old vaccinated) sample.

P02-002-228

Patterns of exposure to bovine herpesvirus-1 and -4 in Irish cattle

Ronan Oneill¹Clare Gallagher¹Jamie Tratalos²David Graham³

¹Virology Division, DAFM Vet Labs, Celbridge, ²CVERA, University

College Dublin, Dublin, ³Animal Health Ireland, Carrick-on-Shannon, Ireland

Objectives: Herpesvirus infections cause a range of clinical syndromes in cattle – respiratory, reproductive, systemic and nervous. Although bovine herpesvirus 1 (BoHV-1) is the most prominent due to semen collection centre controls and eradication programmes in several European countries, bovine herpesvirus 4 (BoHV-4) shares many of the former's features in terms of life cycle and clinical signs. This study for the first time explores the patterns of exposure to BoHV-1 and BoHV-4 in Irish cattle and examines and compares the associations with individual animal and herd level factors.

Materials and Methods: A formally constructed random survey (1,589 sera from 318 herds) was conducted in early 2013 within the last full national testing round for Brucellosis. Samples were tested by ELISA for antibodies to BoHV-1 and BoHV-4 using blocking (IBR gB Ab, IBR gE Ab; IDEXX Laboratories, US) and indirect (BHV-4 Ab BioK 312; BioX diagnostics, Belgium) ELISAs respectively, according to the manufacturers' instructions. Contemporaneous descriptive and epidemiological data at animal and herd levels at the time of sampling were obtained from the Animal Health Computer System (AHCS) of the Department of Agriculture, Food and the Marine (DAFM). Both descriptive and regression analyses were performed. An animal status of BoHV-1-infected was assigned if testing positive by both IBR gB AND IBR gE ELISAs, while a status of BoHV-1-vaccinated was assigned to animals testing IBR gB ELISA positive AND IBR gE negative.

Results: Individual animal antibody prevalence rates were 31%, 14% and 44% for BoHV-1 infected, BoHV-1 vaccinated and BoHV-4 infected respectively. The mean within-herd prevalence for BoHV-1-infection, excluding negative herds, was 12.3% while the mean within-herd prevalence for BoHV-1 vaccinated, excluding negative herds, was 6.3%. The mean within-herd prevalence for BoHV-4 infection, excluding negative herds, was 14.0%. For both BoHV-1 infection and BoHV-1 vaccination, the distribution of within-herd prevalence levels was biased to the left, so that incrementally a smaller proportion of herds show higher prevalence rates. However this pattern was not observed in BoHV-4-infected herds, where 100% of samples tested positive in 17% of herds. The mean individual prevalence levels for BoHV-1 infection was similar across Dairy, Beef, Suckler and Other herd types (as listed on AHCS) at 32.3% ,but much higher in Dairy herds for both BoHV-1 vaccination and BoHV-4 infection at 21% and 73%, respectively. The strongest breed association was a high seropositivity (78%) to BoHV-4 in Friesians. Individual animal age had a clear positive association with antibody prevalence to both BoHV-1 and BoHV-4 infections but not BoHV-1 vaccination. If an animal was still in its herd of birth this was strongly associated ($p < 0.0001$) with a negative BoHV-1 infection status, but no association was detected with BoHV-1 vaccination or BHV-4 infection.

Conclusions: BoHV-1 and BoHV-4 infections are frequent and widespread throughout Ireland. The two viruses appear to have independent distributions and patterns of exposure which may reflect the long-standing awareness of and available active control measures for BoHV-1 in contrast to BoHV-4. In particular, the striking association of BoHV-4 infection with dairy herds and Friesian-breed cattle is worthy of further investigation and research.

Rapid serological detection of Bovine herpesvirus-1 using nanosensors.

Caoimhe Robinson ^{1,2,*} Alan O' Riordan ¹ Niamh Creedon ¹ Riona Sayers ²

¹Nanotechnology, Tyndall National Institute, Cork, ²Animal & Biosciences, Teagasc, Moorepark, Fermoy, Co. Cork, Ireland

Objectives: Bovine herpesvirus-1 (BoHV-1), causative agent of infectious bovine rhinotracheitis (IBR) is an important respiratory pathogen of cattle internationally. IBR spreads rapidly through a herd once introduced, and early detection is critical in preventing transmission to herd cohorts. This is especially important in semen collection stations and cattle feedlots where losses due to the spread of BoHV-1 can be considerable. The objective of this project was to develop a nanosensor-based prototype to allow rapid serological detection of BoHV-1 in bovine serum samples.

Materials and Methods: A fully integrated electrochemical-based nanowire platform was fabricated on a silicon wafer using electron-beam lithography. The nanowires were functionalised using an electrodeposited polymer in order to form the attachment chemistry. The commercially sourced whole virus BoHV-1 (APHA Scientific, UK) was covalently attached to the on-chip gold nanowires using a solution of N-ethyl-N-(dimethylaminopropyl)-carbodiimide (EDC) and N-hydroxysuccinimide (NHS). Ethanolamine was deposited as on the nanowire after the protein immobilisation as a blocking step to fill remaining unbound active sites. Ferrocene monocarboxylic acid (FcCOOH) in phosphate buffered saline (PBS) were purchased from Sigma-Aldrich and used as a redox probe to undertake the cyclic voltammetry and electrochemical impedance analysis. Archived BoHV-1 positive and negative bovine serum samples were provided by Teagasc (Moorepark, Ireland). Detection of BoHV-1 antibodies (Ab) in serum was undertaken using electrochemical detection methods i.e. cyclic voltammetry (CV) and faradaic electrochemical impedance spectroscopy (EIS) were performed to track antibody-antigen (Ab-Ag) binding on the nanowire surface.

Results: The CV and EIS response obtained after each step in the nanowire functionalization showed an increase in the impedance nyquist semicircle and a decrease in the current intensity for the CV plots. This is the expected response as the modification step is limiting the charge transfer from the FcCOOH at the nanowire surface. Detection of the BoHV-1 antibody was first undertaken in buffer solution, followed by detection in 1% bovine sera. The sensor showed a significant increase in nyquist plot after emersion in the 1 µg/ml Ab/buffer solution for 20 minutes, which indicates that the antibody successfully bound to the immobilised virus on-chip. Furthermore, the sensor exhibited the same behaviour in the presence of BoHV-1 positive bovine serum demonstrating that the target antibody present in infected bovine serum is captured by the virus probe. Negative (uninfected) bovine serum samples caused minimal electrochemical change. This highlights that the sensor is specific for serological detection of BoHV-1 and there is no interference from non-specific binding. With the development of a microfluidic system the response time and sensitivity may be improved. Additionally, as there are six independent nanowires on each sensor chip, it is proposed to develop a multiplexed device which would allow simultaneous detection of both anti-gE and anti-gB antibodies using specific viral antigens, rather than whole virus.

Conclusions: A lab-based biosensor prototype has been successfully developed which allows rapid detection of anti-BoHV-1 antibodies in bovine serum. The ultimate aim is to deploy this nanosensor to a farm environment, which will allow real-time identification of BoHV-1 seropositive individuals. The rapidity with which results can be generated

will allow potentially infectious animals to be isolated in a timely manner, thereby reducing further herd transmission of the virus.

Vaccination with a modified-live followed by an inactivated IBR marker vaccine prevents abortion in cattle following challenge with abortogenic BoHV-1

Monika Raue¹·Rüdiger Raue¹Todd Meinert²Sarah Fraser³Frédéric Descamps¹

¹Zoetis, Zaventem, Belgium, ²Zoetis, Kalamazoo, United States, ³Moredun Scientific, Penicuik, United Kingdom

Objectives: Modified-live and inactivated gE deletion marker vaccines against bovine herpesvirus 1 (BoHV-1) are widely used. Efficacy of a combined protocol with two vaccines containing BoHV-1 gE negative strain Difivac has been shown against respiratory disease but not yet against abortion. Here, the results from a masked, randomised, negatively controlled study are reported where pregnant heifers were challenged with abortogenic BoHV-1 after a single dose priming with a modified-live marker BoHV-1 vaccine (Rispoval® IBR Marker Vivum, Zoetis) and a single dose booster with an inactivated marker BoHV-1 vaccine (Rispoval® IBR Marker Inactivated, Zoetis).

Materials and Methods: Forty-four (44) Holstein heifers, aged between 14 and 16 month and without antibodies to BoHV-1, were enrolled into the study and randomly allocated to one of two treatment groups. The vaccinated group was first vaccinated with a modified-live vaccine (Rispoval® IBR Marker Vivum, Zoetis) followed by a second vaccination six months later of the now pregnant heifers with an inactivated vaccine (Rispoval® IBR Marker Inactivated, Zoetis). In the non-vaccinated control group, heifers received two mock-vaccinations with water for injection at the same time-points. Approximately three months after the final vaccination, between 203 and 204 days of gestation, 12 pregnant heifers of each group were randomly selected and challenged intravenously with the abortogenic BoHV-1 strain Cooper. The impact of vaccination on serology, clinical parameters, abortion rate and off-spring viability was compared to 12 non-vaccinated control heifers. Tissue samples of aborted fetuses or stillborn calves were collected for serology, virus isolation, immunohistochemistry and histopathology. All sample analysis was conducted by personnel masked to the treatment group allocation of individual animals.

Results: Following experimental challenge, nine out of 12 control heifers (75%) aborted. Histopathology in lung, liver and kidney and BoHV-1-specific immunohistochemistry on lung, liver and kidney samples confirmed that all nine abortions were attributable to BoHV-1 infection. Ten out of 12 vaccinated heifers gave birth to normal healthy calves and the remaining two vaccinated heifers had a stillbirth. Sera from nine healthy calves were seronegative in the BoHV-1 serum-neutralisation test (pre-colostral blood sample); one healthy calf had a titre of 48. Sera collected from the two stillborn calves were negative in the BoHV-1 serum-neutralisation test, and no evidence for BoHV-1 infection could be found at histopathological investigations of samples from the calves' lungs, livers and kidneys. BoHV-1-specific immunohistochemistry was negative and BoHV-1 isolation on liver samples was also negative. Therefore, these two stillbirths were not attributed to BoHV-1 infection. There was a significant difference ($p=0.0158$) between treatment groups in the number of abortions and stillbirth attributable to BoHV-1 infection using Fisher's Exact Test.

Conclusions: This study demonstrates that administration of the modified-live BoHV-1 marker vaccine used in this study (Rispoval® IBR Marker Vivum, Zoetis) followed six months later by the inactivated BoHV-1 marker vaccine (Rispoval® IBR Marker Inactivated, Zoetis) induces protective immunity against infection with abortogenic BoHV-1, as demonstrated by an absence of abortions and stillbirths due to BoHV-1 and an absence of in utero infection of the foetus in 11 of 12 pregnancies.

P02-002-231

Free from Bovine Herpesvirus 1 (BoHV1) is not the end of the story

Jens Boettcher¹·Benjamin Motsch¹Norbert Meier¹Maria Hagg¹Britta Janowitz¹

¹Bavarian Animal Health Service, 85586 Poing, Germany

Objectives: Since October 2011 the federal state of Bavaria is listed as an article 10-region according to directive 64/432/EEC. Serological cross-reactivity due to BoHV2 infection interferes with BoHV1-tests. A modified gE-ELISA (Idexx, Ludwigsburg, cut-off 0.95) solved the problem at the level of blood testing (Böttcher et al., 2012), but the problem remained unsolved at the level of bulk-milk (BM)-surveillance.

An indirect gE-ELISA for BM-testing (Eradikit BoHV1-gE, bulk milk surveillance kit, In3diagnostics, Turino (IT)) was compared with the routine procedure of BM-surveillance.

Materials and Methods: Surveillance is currently performed by BM-testing with Trachitest (Idexx). Non-negative results are confirmed by a second manually collected BM (Trachitest) and/or blood samples. Blood samples are tested with Trachitest/gB-ELISA (Idexx) and in case of less than four gB-positives per herd the modified gE-ELISA is applied.

The protocol of Eradikit for IgG-concentration was compared with ammonium sulfate precipitation (ASP) for IgG1 (mg/ml) and Eradikit results.

Eradikit protocol was modified to increase the sensitivity: The pellet after ASP was dissolved in sample diluent and tested without any further dilution. The positive control was diluted 1/8 (instead of 1/2) and sample incubation was performed overnight at 4°C (instead of 1 hour at room temperature). A preliminary cut-off at 50% was implemented.

Eradikit was analyzed with 6 positive milk samples supplied by the manufacturer and 17 individual milk samples from two non-vaccinated and BoHV1-infected dairy cow herds, kindly supplied by Antonio Barberio and Stefano Nardelli (Istituto Zooprofilattico, Padova (IT)). Additionally, 20 BMs from a BoHV2-affected (18 non-negative in Trachitest) and 22 BMs from a non-affected Bavarian region (negative in Trachitest) were included. BoHV1-positive individual milk samples were diluted 1/25 and 1/50 in negative milk and subsequently processed as BM in Trachitest and Eradikit.

Finally, BMs from 387 herds with initial non-negative results in Trachitest, which were not confirmed by the routine procedure, and 8 BMs from herds with confirmed BoHV1 were parallel tested with Eradikit.

Results: ASP was simple, cheap, robust and gave better results i.e. higher IgG-concentration, higher detection rate of positive samples and lower background. Additionally, the re-suspended volume allowed testing of duplicates or even retesting.

50% and 70% of the spiked BoHV1-positive milk samples scored positive at a dilution 1/50 and 1/25, respectively. In contrast, only one sample of the BoHV2-negative region scored positive.

Implementation of Eradikit at the level of the first BM reduced the number of suspicious herds from 387 (100%) to 14 (3.6%). In 2015 an outbreak of BoHV1 occurred, BMs from 8 affected herds tested positive in Eradikit with values (OD%) $\geq 150\%$.

Conclusions: Eradikit is a suitable tool to improve BM-surveillance in article-10-regions; it speeds up the surveillance and reduces the costs. However, the current paradigm of BoHV1-surveillance needs to be changed. Currently, it relies on detection of one weak-positive milk sample in a pool of 50 in order to detect a single latently infected cow in a herd. This is very useful in regions with eradication programs (i.e. Article 9), but surveillance in article-10-regions should rather focus on rapid detection of farms with re-infection which is associated with virus spread, strong ELISA-reactivity and high seroprevalence.

Comments: This study was financially supported by the Free State of Bavaria and the Bavarian Joint Founding Scheme for the Control and Eradication of contagious Livestock Diseases.

IBRV Reproductive Loss- Vaccine or Field Virus Using Single Nucleotide Polymorphisms (SNPs) to Sort out Vaccine-Induced Reproductive Disease

Chris Chase¹, Lyle Braun¹, Travis Clement², Russell Daly¹, Grant Burcham³, Donal O'Toole⁴

¹Veterinary and Biomedical Sciences, South Dakota State University, Brookings SD, ²Veterinary and Biomedical Sciences, South Dakota State University, Brookings, ³Heeke Animal Disease Diagnostic Laboratory, Southern Indiana Purdue Agricultural Center, Dubois, IN, ⁴Veterinary Sciences, University of Wyoming, Laramie WY, United States

Objectives: Modified live virus (MLV) bovine herpesvirus 1 vaccines have been a major aid to the prevention of reproductive disease in cattle. However their use (or misuse) can result in major abortions storms. Determine if single nucleotide polymorphisms (SNPs) in IBRV can be used as a method to resolve whether outbreaks were likely to be iatrogenic (vaccine induced).

Materials and Methods: To determine the SNP pattern of a virus, the entire virus must be sequenced and then the vaccine viruses matched up with a "known" laboratory virus. Using methods developed by Fulton et al, 2013 (Fulton, R. W., d'Offay, J. M., & Eberle, R. Bovine herpesvirus-1: Comparison and differentiation of vaccine and field strains based on genomic sequence variation. 2013. Vaccine, 31(11), 1471-1479). The sequences were then compared and SNPs were identified. Using this information 3 different segments were compared and individual SNP were identified. The unknown virus isolate is then compared to the known SNP for the vaccines. This analysis was done on either virus isolates or infected tissues (either placenta or fetus).

Results: We have had 15 abortion episodes (10 from Wyoming, 2 North Dakota, 2 from Minnesota and 1 from Indiana) where we have virus isolates between 2010- 2015 where an apparent association existed between use of modified live BoHV-1 and abortion in the subsequent 1-8 months. In individual episodes the products were either used "on or off label" according to the producer. All 15 isolates had SNP patterns

consistent with those of commonly used modified live BoHV-1 strains. Use of SNP patterns is helpful in resolving whether abortion was likely due to "vaccinal virus" particularly when disagreement existed between a producer and representatives of the vaccine manufacturer

Conclusions: Use of vaccines containing MLV BHV-1 in has inherent risks to reproductive fitness. Fifteen different cases were tested using SMPs. These cases reinforce the need to make sure the cow herd is adequately vaccinated if calves are vaccinated with MLV vaccine while still with the cows. However when "properly vaccinated" heifers have higher susceptibility to MLV induced abortion. In summary, MLV BHV-1 vaccines must be used judiciously following label directions. In spite of the following the label, reproductive issues can still occur.

P02-002-233

Severe Bhv-1 Outbreak In A Naive Dairy Herd In Northwest Spain

Marta Souto Martínez¹, Iván Mato Iglesias²

¹Vet practitioner, Lugo, ²Hipra, Amer, Spain

Objectives: The commercial dairy herd is located in Galicia (North West of Spain), a densely populated region with farms that average a capacity of 40 cows. This is a large herd with 400 dairy cows (250 milking) and it is engaged in a voluntary regional health program for the control and eradication of IBR, BVD, Neospora and Johne's disease. This farm has regularly vaccinated for BVD and it was considered to be free of IBR according to yearly serology control for IBR and bulk tank milk analysis followed in the region.

Materials and Methods: In June 2014 this farm was presented with a respiratory outbreak that was mainly affecting the adult animals. Pyrexia (40°C-40,5°C), anorexia, dyspnea, cough and nasal discharge, firstly serous and then muco-purulent, also combined with conjunctivitis and ocular discharge. One animal died and at post-mortem it was evidenced pneumonic consolidation and emphysema. The average milk production of the herd was decreased by 2 liters per animal. Young suckling calves were also affected, and the group of calves showed the same respiratory clinical signs, and of those one 4 month old calf died few days later.

Results: All the affected animals were first treated with nonsteroidal anti-inflammatories, marbofloxacin and ceftiofur, although little success was found. One week after the symptoms appeared it was decided to do an intranasal vaccination against BRSV and P-I3 in milking animals, and 10 days later that same vaccine protocol was extended to the whole herd. The farmer, due to the poor response to the vaccination decided then to contact the veterinarian of the regional health program.

The veterinarian did the anamnesis, farm inspection and clinical examination and he finally suspected of an IBR outbreak as the main cause of the problem. He then took some nasal swabs for virus detection (IBR, BRSV, BVD) by PCR (Boviresp FTA®, Hipra) (1). This analysis came back as positive for IBR and some days later it was evidenced IBR seroconversion in blood samples from 12 to 24 months old heifers and also in milk samples from the bulk tank.

Conclusions: In front of the evidence of the lab results obtained the veterinarian decided the introduction of an MLV IBR marker vaccine gE-/tk- deleted (Hiprabovis® IBR Marker Live, Hipra) to the whole herd. The symptoms then began to decrease in just 48h after vaccination, no more

animals became sick after the introduction of the vaccine and the milk production went back to normal levels.

Comments: Currently this herd is on a six monthly program with HIPRABOVIS® IBR Marker Live protocol for the prevention of IBR, with a double primo-vaccination in the young heifer calves at 3 months of age and booster vaccinations in the adults every 6 months. The farm IBR status is regularly monitored by bulk milk tank sampling every 6 months and every 12 months by the sampling and IBR gE serology of 12- 24 months old heifers. No more clinical cases of IBR have been detected and the epidemiologic situation of IBR is now under control.

IBR

P02-002-234

Reduction in daily milk yield associated with sub-clinical Bovine Herpes Virus 1 infection

Jonathan Statham^{1*} on behalf of RAFT Solutions Ltd Laura Randall^{1,2} on behalf of RAFT Solutions & Nottingham University Simon Archer² on behalf of Nottingham University

¹RAFT Solutions Ltd, Ripon, ²Nottingham University, Nottingham, United Kingdom

Objectives: Bovine Herpesvirus 1 (BoHV-1) incursion into a naïve population of adult dairy cows typically leads to a variety of clinical syndromes described as Infectious Bovine Rhinotracheitis (IBR). BoHV-1 may also persist and lead to sub-clinical disease with insidious production losses and potentially serious economic consequences. The longer term effects on milk production of sub-clinical BoHV-1 remain unknown and it is important in understanding the relative importance of IBR control. This study aimed to investigate the effect of sub-clinical BoHV-1 infection on milk production over a 2 year period on a UK dairy herd.

Materials and Methods: Infection status of cows (infected or not infected) in a closed autumn-calving dairy herd was assigned from serology on a single occasion in May 2010. We infer nothing about the temporal dynamics of virus circulation in the herd, other than the observed change in herd classification based on bulk milk serology. The herd comprised of 129 pedigree Holstein cows with approximate annual milk yield of 9,000 kg per cow. A multi-level linear model was used to evaluate the impact of infection status on milk production, using milk records that were routinely collected over two years from January 2009 to December 2010. Based on bulk milk serology and intermittent blood samples from young stock up to February 2010, the herd was assumed previously uninfected with BoHV-1.

Results: Seventy two per cent of cows were seropositive to BoHV-1 on individual blood samples taken in May 2010. Risk of sero-conversion varied with parity, with a higher proportion of parity 1 and >4 testing positive. Importantly, cows that were seropositive to BoHV-1 in May 2010 produced 2.6 kg per day less milk throughout lactation compared to those that were seronegative. This was further highlighted through the production of a mean predicted lactation curve for parity one cows in December with mean milk fat, protein and somatic cell counts based on BoHV-1 antibody status. It clearly demonstrated that peak lactation was reached at the same time point, irrelevant of antibody status, but animals that were seropositive to BoHV-1 peaked at a considerably lower milk yield. The decline in yield over the course of lactation was predicted to occur at the same rate, irrelevant of antibody status, indicating that those that were seropositive to BoHV-1 maintained a considerably lower yield throughout lactation. Compared to seronegative cows, those cows with

antibodies to BoHV-1 on average failed to produce almost 1,000 kg of milk per year.

Confounding factors influencing test day milk yield were calendar month, parity, stage of lactation, test day fat and protein percentage and somatic cell count. Residuals from the data were normally distributed indicating a good fit to the data.

Conclusions: Sub-clinical BoHV-1 infection has been associated with a large decrease in potential daily milk yield. This potential fall in production is larger and predicted to last longer than previous estimates. This variation could relate to differences between studies, disease dynamics, BoHV-1 strain or the analysis. The large potential losses in milk production highlights the importance of herd health management to prioritise management interventions such as; biosecurity and vaccination. It also highlights the vitality of effective monitoring to mitigate the effects of sub-clinical disease.

Preparation and first 4 years of the mandatory IBR-program in Northern-Belgium

Stefaan Ribbens^{1*} Willem Van Praet¹ Eva van Mael¹ Leen Van Schoubroeck¹

¹Animal Health Care Flanders, 9031 Drogen, Belgium

Objectives: IBR (infectious bovine rhinotracheitis) is caused by BoHV-1. Starting from January 5th 2012, participation to the national IBR-eradication programme became mandatory in Belgium. In the year 2010-2011, all cattle owners in Belgium are preparing for IBR-control either through vaccination or blood sampling. This abstract describes the “starting-up” phase of the national IBR-campaign in Northern-Belgium and the experiences of the first 4 years of the program from a perspective of animal health care Flanders.

Materials and Methods: Cattle owners in Belgium can obtain an IBR-‘status’ either through marker-vaccination or through blood sampling in animals for IBR antibodies. To start IBR-control, farmers were advised to determine their IBR status through an initial herd sample consisting of approximately 26 ‘representative’ animals, analysed for gE or gB antibodies (Idexx). After interpretation of this herd-sample and/or combined with herd anamnesis, it is decided which status is to be obtained: ‘12’-status (mandatory vaccination), ‘13’-status (free of wild-virus) or ‘14’-status (free of both virus- and vaccine- antibodies). Free-status (13/14) is obtained after two consecutive negative gE/gB screenings (all animals above 12 months). Status has to be maintained through yearly blood sampling, bi-annual vaccination and is accompanied by biosecurity restrictions. Herds without a status are categorised as ‘11’ and will be blocked in 2012 (limited to removal of animals directly for slaughter).

Results: In this abstract, the situation until October 2015 is given. At the beginning of the program in 2012 2.900 cattle herds obtained a ‘13’ or ‘14’ status (free of BHV-1). About 8.300 herds performed an initial herd sample to determine their infection status. 72% of all vaccinating herds (‘12’-status) never sampled their animals to determine their IBR-infection status. In October 2015, the number of herds obtaining a free status was 5.068 or 33% of cattle herds in Northern-Belgium. Results indicate that though systematic control the between-herd prevalence and within herd prevalence of BHV-1 is diminishing.

Conclusions: The evolution of IBR-control, restraints and the experienced difficulties of the “starting-up phase and first 4 years will be discussed. Focus will lie on farmers and herd veterinarians choices (vaccination or obtaining a free status) and motivators in a mandatory IBR-control, coupled with the communication campaign conducted at Animal Health Care Flanders to guide Northern-Belgian cattle owners to a form of IBR-control.

P02-002-236

Interim Report of a Long-term BoHV-1 Eradication Program in Polish Dairy Cattle Herds - Success and Risk

Rypuła Krzysztof¹ Katarzyna Płoneczko-Janeczko¹ Karolina Bierowiec¹ Aleksander Hamala² Marek Lesiak³ Monika Rau⁴

¹Faculty of Veterinary Medicine, University of Environmental and Life Sciences, Wrocław, Poland, ²Veterinary Practice, Wądroże Wielkie, Poland, ³Zoetis, Warszawa, Poland, ⁴Zoetis, Zaventem, Belgium

Objectives: Bovine herpesvirus 1 (BoHV-1) causes infectious bovine rhinotracheitis (IBR), abortions and other syndromes in cattle. In many parts of the world, vaccination is used as an important tool in BoHV-1 control and eradication programs. With parts of Europe now IBR free, the ability to differentiate infected from vaccinated animals (DIVA) has become critical as a trading tool. For this purpose, modified-live and inactivated gE deletion marker (gE negative) vaccines were developed. The objective of this study is to evaluate the efficacy of different DIVA vaccination protocols to aid in the eradication of BoHV-1 from Polish dairy cattle herds.

Materials and Methods: A total of approximately 5000 cattle from 5 dairy farms were included in the study in January 2014. All farms had already started eradication programs between 2005 and 2013. During the study, two commercial vaccines, a modified live vaccine [Risposal[®] IBR Marker Vivum (VV); Zoetis] administered intranasally (IN) or intramuscularly (IM) and an inactivated vaccine [Risposal[®] IBR Marker Inactivated (VI); Zoetis] administered subcutaneously, were used as follows:

Farm A (1300 animals): VI at 3-4 months of age and again after 3-4 weeks, then VI at 6 monthly intervals.
 Farm B (800 animals): VI at 6 months of age and again after 3-4 weeks, then VI at 6 monthly intervals for 2 years followed by yearly intervals.
 Farm C (1200 animals): VI at 6 months of age and again after 3-4 weeks, then VI at 6 monthly intervals for 3 years followed by yearly intervals.
 Farm D (800 animals): VV at 2 months of age IN and after 3-5 weeks IM, then VI at 6 monthly intervals for 2 years followed by yearly intervals.
 Farm E (690 animals): VV at 6 months of age IM, then VI after 6 months, followed by VI every 12 months.

To determine BoHV-1 seroprevalence, serum samples were collected from study animals at 7-9 months of age, 12-13 months of age and at 1st, 2nd 3rd etc. lactation. In cows serum samples were collected from randomly selected 20% of animals. Samples were analysed by ELISA (HerdCheck BHV1 gE; IDEXX, Scandinavia AB, Sweden) for antibodies against the gE protein of BoHV-1.

Results: The ELISA results confirm, that the percentage of animals with antibodies to BoHV-1 gE has been decreasing in each of the vaccinated herds over time. In Farm A (gE-positive animals: 79% in 2013, 43% in January 2014, 35% in December 2014, 14% in October 2015), seroprevalence decreased continuously due to vaccination and culling

of gE-positive animals. On Farm B (gE-positive animals: 100% in 2005, 0%, In January 2014, 0% in December 2014, 0% in October 2015) and on Farm C (gE-positive animals: 100% in 2006, 5% in January 2014, 0% in December 2014, 0% in October 2015), the BoHV-1 free status is maintained through 6-monthly vaccinations with the inactivated vaccine. On Farm D (gE-positive animals: 90% in 2008, 76% in January 2014, 48% in December 2014, 48% in October 2015 with 0% of gE-positive animals in the age group 7-13 months), continuous improvements in eradication are observed as replacement animals grow up BoHV-1 free and older animals are removed from the herd. On Farm E (gE-positive animals: 100% in 2013, 78% in January 2014, 53% in December 2014, 27% in October 2015), heifers from different sources were brought into the herd in late autumn 2014, without quarantine procedures or serological testing. Subsequent serological testing showed that the decrease in the percentage of gE-positive animals in the herd had slowed down, and counter measures such as culling were implemented to prevent a BoHV-1 outbreak.

Conclusions: The interim results of this study lead to the following conclusions:

1. DIVA vaccination programs with live and inactivated BoHV-1 (Risposal IBR Marker) vaccines are an effective tool in the eradication of IBR in dairy cattle herds.
2. Continuous serological testing especially of young animals is recommended.
3. Good management practices such as identification of BoHV-1 gE-positive animals and biosecurity measurements are essential for the success of BoHV-1 eradication programs.

IBR

P02-002-237

Control and Monitoring of Infectious Bovine Rhinotracheitis in a Closed Dairy Herd Following Vaccination with Live/Inactivated IBR Marker Vaccine

Julie Forrest¹ Alastair Macrae¹ Colin Penny^{2*}

¹Royal (Dick) School of Veterinary Studies and Roslin Institute, Roslin, ²Zoetis UK Ltd, Tadworth, United Kingdom

Objectives: An opportunity arose to study the epidemiology of IBR in a closed (apart from occasional stock bull purchase), 230 cow Holstein dairy herd. Following an IBR breakdown in 2012 the breeding herd was vaccinated with a live/inactivated IBR marker vaccine programme with the aim of controlling clinical disease and reducing risk of subsequent virus shedding from latently infected animals. The herd was closely monitored by individual milk/serum IBR antibody testing over a 4 year period to follow IBR infection status with a view to achieving eradication of IBR from the herd.

Materials and Methods: The herd had excellent boundary biosecurity and homebred heifers were reared on the same farm as cows but housed in separate accommodation until pregnant. Vaccination for IBR had been carried out 2002-2007 (marker vaccine used 2006/7) but ceased in October 2007. IBR status was then monitored by annual, first lactation heifer cohort, milk IBR antibody testing.

In May 2012, a milking heifer showed clinical signs of IBR and died, with IBR confirmed by PCR testing and histopathology.

Herd status was investigated by testing all cows for milk or blood IBR gE antibody (IDEXX Elisa) to define herd seroprevalance. Bulling and in-calf

heifers plus the stock bull (IBR free at purchase) were blood tested for IBR gB antibody (Biobest indirect ELISA).

The breeding herd (all cows, pregnant and bulling heifers) were vaccinated i/m with a live IBR marker vaccine (Risposal® IBR Marker Live ,Zoetis) followed 4 weeks later by an inactivated IBR marker vaccine (Risposal® IBR Marker Inactivated ,Zoetis) s/c and boosted annually with inactivated IBR vaccine. In subsequent years the bulling heifers received a primary vaccination course of live IBR vaccine i/m followed 4 weeks later by inactivated IBR vaccine before breeding and then boosted annually with inactivated IBR vaccine. Monitoring continued with annual individual IBR gB antibody blood testing of bulling heifers prior to vaccination, IBR gE antibody blood testing of in-calf heifers and individual milk IBR gE testing of cows from 2012-2015. At the 2014 test both milk and blood samples were taken from cows on the same day.

Results: First lactation heifer cohort milk IBR gB antibody testing between 2008 and 2011 proved negative suggesting absence of active infection in the milking herd during this period.

The individual IBR antibody percentage sero-positivity for herd groups for years 2012-2015 respectively were :

Bulling heifers : 1%(n=90), 0%(n=105), 0% (n=96) and 0% (n=119).

In-calf heifers : 68%(n=69), 1%(n=90), 0%(n=105), not tested in 2015 but all negative as bulling heifers.

Milking cows : 99%(n=230), 91%(n=228), 63%(n=235) and 45%(n=226).

The stock bull tested IBR antibody positive in 2012 having previously been confirmed IBR free at entry to herd.

The sampling results showed that in 2012 IBR appeared to have spread widely in the milking herd and the in-calf heifers that had been mixed with dry cows. In the six months prior to this the herd had experienced no "classical" signs of IBR but poorer than average herd fertility had been noted. Following vaccination of the breeding herd the subsequent replacement heifer cohorts have remained IBR free to date. The cow herd seroprevalance fell from 99% to 45% in a 3 year period with normal culling policy.

The comparison of individual milk and serum IBR gE (IDEXX Elisa) cow test results done in 2014 showed reasonable correlation but suggested false positives are likely with a single milk gE test sample. The correlation for 213 milk/blood sampled cows were as follows :

Milk gEpos/serum gE pos	128
Milk gE neg/serum gE neg	74
Milk gE pos/serum gE neg	10
Milk gE neg/serum gE pos	1

Conclusions: Within 5 years of ceasing an IBR vaccination programme the disease appeared to recrudescence and spread widely in this herd.

Vaccination with a live/inactivated IBR marker vaccine programme has to date controlled clinical disease and possibly reduced the risk of latent carrier cows shedding virus and infecting naïve heifers.

Within 3 years the adult cow herd seroprevalance has fallen from 99% to 45% suggesting with current replacement/cull rates eradication could be achieved within 5-6 years of initial diagnosis by removing residual latent carriers.

Application of a new method for MHC class I immunotyping applying RNA-Seq with regard to the aetiopathogenesis of bovine neonatal pancytopenia (BNP)

Wiebke Demasius^{1*}Rosemarie Weikard¹Frieder Hadlich¹Johannes Buitkamp²Christa Kühn¹

¹Institute for Genome Biology, Leibniz Institute for Farm Animal Biology (FBN), 18196 Dummerstorf, ²Institute for Animal Breeding, Bavarian State Research Center for Agriculture, 85586 Grub, Germany

Objectives: Bovine neonatal pancytopenia (BNP) is an alloimmune-mediated disease, which is induced by ingestion of colostral alloantibodies from some dams, which have been vaccinated with a specific vaccine. It has been proposed that after vaccination contaminating MHC class I from the producer cell line (Madin-Darby bovine kidney cell line, MDBK) of this vaccine elicit alloantibody production against MHC class I in some dams (BNP-dams). No specific, causative MHC class I alleles for BNP have been identified. Additionally, the Immuno Polymorphism Database (IPD-MHC BoLA) contains only a limited number of published MHC class I sequences for *Bos taurus*.

Materials and Methods: In consideration of the limited MHC class I allele catalogue and complex MHC class I haplotypes in cattle, we developed a new strategy for immunotyping of classical and non-classical MHC class I alleles at nucleotide level. High-throughput mRNA sequencing from whole blood samples of dams with divergent BNP phenotypes and the MDBK cell line was carried out as a paired-end, 2x61bp approach. Alignment of reads obtained from sequencing was performed with different Bowtie options. A catalogue of previously published MHC class I alleles served initially as reference sequence. Applying less stringent alignment options subsequently enabled deduction of novel alleles from previously published alleles. The initial allele catalogue was extended with newly discovered alleles for further and final alignment. The method additionally enabled quantification of MHC class I expression on allele level. Expressed MHC I alleles of BNP-cows, non-BNP cows and the MDBK cell line were compared with respect to a potential causative BNP allele.

Results: We obtained a comprehensive list of expressed classical and non-classical MHC class I alleles, including previously published alleles and several, previously unpublished alleles. Expression of identified MHC class I alleles could be confirmed by Sanger sequencing. The detection of novel MHC class I alleles provides further sequence information for a currently incomplete MHC class I sequence set in cattle. MHC class I alleles expressed by BNP-dams, control dams and the producer cell line of the vaccine were subsequently compared at nucleotide level as well as on amino acid level. This enabled us to gain further insights into the aetiopathogenesis of BNP. No specific MHC class I allele or amino acid position could be detected as BNP causative allele or amino acid position. Regarding the quantification of MHC class I alleles, expression levels of single assigned alleles varied within individuals, while the relative proportion of reads assigned to alleles was strikingly constant.

Conclusions: Our results show that our new MHC class I immunotyping strategy is applicable to detect unknown and already published MHC class I sequences in cattle. Regarding BNP, application of the novel approach has provided evidence that specific classical and non-classical MHC class I can be excluded as single causal agents for BNP-associated alloantibodies.

Effectiveness of a new recombinant immunocastration vaccine in bovine

Leonardo Saenz¹Paula Ramirez²Lisette Lapierre¹John Quiroga¹Mario Maino^{2*}

¹Vaccivet, ²Universidad de Chile, Santiago, Chile

Objectives: Animal castration for meat production is a widely used method since it allows the inhibition of sexual and aggressive behavior of animals. Recently, a new technology has been developed called immunocastration, which through the generation of neutralizing antibodies against the hormone GnRH, is able to block temporarily the hormone activity, preventing the production and release sex steroids. The aim of this work was evaluate a new recombinant immunocastration vaccine for use in cattle in a field clinical trial to evaluate safety and efficacy, by determining its effect on a number of hormonal, behavioral and production parameters.

Materials and Methods: The vaccine composition will be based on the use of a recombinant antigen of the hormone GnRH-I (EP 2431052 B1) and an adjuvant based on low molecular weight Chitosan. A group of 90 animals were vaccinated with GnRX G/Q to 11 months old followed by a new dose 30 days after the first application. The control group was castrated surgically at same time. The clinical trial was evaluated using the standards of Good Clinical Practices during 6 months. Serum samples were taken at day -30, 30, 80, 122 and 165 to evaluate testosterone levels and specific rise of immunoglobulins against GnRH. Productive parameters as final weight, dressing, quality of meat and sexual behavior were evaluated. Two-way ANOVA was used as statistics test.

Results: The rise of levels of testosterone was blocked after the second doses and remain low until the 165 day, around 2 ng/ml. The sexual behavior had an increase at day 80, but this fell to day 165 with an increasing of social and agonistic behavior. The final weight was 5% higher in the immunocastration group with 1% less dressing and butter weight of carcass than control group. The quality of meat was similar in fat infiltration, pH and tenderness in both groups. Testicular histology showed a reduction of spermatogenesis in tubules and absence of spermatozoa in epididymis.

Conclusions: This new recombinant vaccine was effective in reducing testosterone levels after two vaccinations, generating a blocking spermatogenesis and sexual activity for 6 months. The quality of meat from animals immunocastrated was very similar to that of surgically castrated animals. The immunocastration achieved a slight but significant increase in productive parameters such as weight and final weight of carcasses.

Vaccination against clostridial disease in maternally derived antibody positive lambs; a randomised, non-inferiority field trial in twin lambs.

J. Moffat¹H. Bain¹S. Bruere²

¹MSD Animal Health, Wellington, ²Vet Services Wairarapa, Masterton, New Zealand

Objectives: In New Zealand (NZ) prevention of clostridial disease by vaccination of ewes 2-6 weeks pre-lamb normally protects lambs until weaning; however, in some flocks, *Clostridium perfringens* type D (i.e. Pulpy Kidney) deaths still occur. Additional vaccination at tailing (~4 weeks old) is used to reduce this risk. As most lambs born to vaccinated dams will have maternally derived antibodies (MDA), it is crucial that a vaccine is efficacious in the face of MDA. This study examined the immune response in MDA positive lambs, vaccinated at tailing.

Materials and Methods: A randomised parallel group, non-inferiority field trial, conducted on a sheep and beef farm in Masterton, NZ. In July 2012, 126 maiden, twin-bearing, Romney, 2-tooth ewes were injected with a single dose of the test vaccine (n=63, Multine™ 5, MSD Animal Health NZ) or the reference vaccine (n=63, Ultravac® 5 in 1, Zoetis NZ). Following randomisation, each lamb within 50 sets of twins was vaccinated with the test or reference vaccine at tailing (V1- aged 26 to 53, median 36 days) and again in 49 days at weaning (V2). Epsilon and tetanus antitoxin concentrations were determined by ELISA at V1 (MDA) and at V2+14 days. Data were reported as geometric mean concentration (GMC) and the geometric mean ratio (GMR) of the test/reference and their [95% confidence interval (CI)]. Failure to respond was defined as a decrease in antitoxin concentration at V2 + 14 relative to V1. The European Pharmacopoeia (EP) vaccine release concentration of 5 and 2.5u/ml for epsilon and tetanus respectively was also used to assess individual response. Non-inferiority was assessed by calculation of the lower limit of the one-sided CI of the GMR at V2 + 14. Non-inferiority was declared if this lower limit was ≥ 0.63 .

Results: Epsilon and tetanus MDA, 0.3-10.5 & 0.1-11.5u/ml resp., were detected in all lambs at V1. Lambs from ewes that got the test vaccine had higher epsilon MDA than the reference (GMC 3.0 u/ml, n = 59 and 1.4 u/ml, n = 60, respectively; GMR 2.1; P < 0.0005). The MDA tetanus GMC was 1.7 and 1.3 u/ml in test and reference groups resp.; GMR was 1.3 (P = 0.056). Epsilon antitox. increased in 13/19 of control lambs indicating some natural exposure prior to V2 +14. Nevertheless, 11/50 lambs with the reference failed to respond; whereas all reference lambs responded. MDA conc. at V1 was neg. associated (P = 0.004) with no response in the reference group; the response % being 100 % with MDA at the 25th perc., compared with 74 % and 30 % at the 75th and 90th perc. resp.. Most (48/50) lambs vaccinated with the test had epsilon antitox. conc. > EP standard, compared with 30/50 of reference lambs (adjusted margin 36%, P < 0.0005). The test product was non-inferior to the reference (GMR lower limit 1.9). Moreover, the test vaccine induced a 2.5x greater mean response (GMR 2.5, P_{Bonf} < 0.0005). Tetanus antitoxin increased in 49/50 and 41/50 of the reference and test lambs resp., no evidence of natural exposure. No response in the reference group was (p=0.005) associated with the MDA conc. at V1. Most (49/50) test lambs had tetanus antitox. > EP standard; compared to 42/50 of the reference lambs (adj. margin 14%, P = 0.010). The test product was non-inferior to the reference (GMR lower limit 1.3). Moreover, the test vaccine induced a 1.8x higher mean response (GMR 1.8, P_{Bonf} < 0.0005).

Conclusions: All lambs had epsilon (Pulpy Kidney) and tetanus MDA at tailing indicating successful colostral transfer. Lambs born to ewes vaccinated with test vaccine had higher MDA, than lambs born to ewes vaccinated with reference vaccine. The test vaccine overcame maternal antibodies and induced a protective immune response, superior to the registered reference product. The test vaccine can be prescribed for use in lambs at tailing when these lambs are born to ewes which have had a clostridial vaccination prior to lambing.

Antibody to leukocidin mitigates the mastitis induced by exosecretion derived from predominant lineage of *S. aureus* isolated from bovine mastitic milk

Toshihiro Ito ^{1,*}Taichi Noro ¹Eiji Oishi ¹

¹Kyoto Biken Laboratories, Uji, Kyoto, Japan

Objectives: *Staphylococcus aureus* (*S. aureus*) is a common etiological agent of bovine mastitis. The specific factors involved in mastitis and its effective treatment are not well understood. We investigated the relationship between *S. aureus* exosecretions and mastitis. We conducted an epidemiologic analysis by comparing genetic variation among *S. aureus* isolates from bovine milk, estimated the inflammatory effect of exosecretions derived from epidemiologically predominant strains both in vitro and in vivo. We further conducted a passive immunization study evaluating the effectiveness of humoral immunity against the inflammatory effects of exosecretions.

Materials and Methods: A total of 97 *S. aureus* isolates from the milk of infected bovine mammary glands collected from 2011 to 2014 from 12 farms in Japan were included in this study. The genes encoding leukocidins (LukM/F, LukE/D, hlg, LukPVL), Sag, enterotoxins (A-I), and TSST were detected using PCR to monitor the variety of exosecretions. *S. aureus* capsular typing and multilocus sequence typing (MLST) were also performed to evaluate the bacteriological lineage. In order to evaluate the leukotoxic activity of exosecretions with different leukocidin profiles in vitro, supernatants of *S. aureus* cultured in brain heart infusion broth were inoculated to granulocytes derived from bovine peripheral blood in microtiter plates. Leukotoxic activity of each specimen was determined as the highest dilution of supernatants, indicating a flattened effect against granulocytes. Supernatants were purified via two step ammonium sulfate precipitation followed by filtration and inoculated into bovine udders. The degree of inflammation was evaluated via somatic cell counts (SCC). A passive immunization study was conducted by pre-incubating LukM/F positive *S. aureus* exosecretions with immune serum, which neutralized the leukotoxic activity before inoculation into the bovine udder. The expression of cytokines (IL-1, IL-6, IL-8, and TNF- α) by milk cells was additionally characterized using real-time RT-PCR to estimate the degree of inflammation.

Results: Almost all the *S. aureus* strains derived from bovine mastitis possessed LukE/D and hlg genes, and 54% of the strains possessed the LukM/F gene. In contrast, enterotoxin, PVL, and Sag genes were rarely found. The dominant *S. aureus* lineage, Capsular type 5 - MLST CC97, was strongly correlated with the presence of LukM/F genes. Exosecretion of LukM/F positive strains showed significantly higher cytotoxic activity against bovine granulocytes in the range of 800-6400 compared with exosecretion of LukM/F negative strains (<10-40). Both semi-purified exosecretions of LukM/F positive and negative strains induced mastitis 8 to 24 hours after inoculation into bovine udder, but the clinical signs were significantly greater with the former specimen (SCC= 467 x10⁴ and 106 x10⁴ /ml of the peak). This inflammatory effect was mitigated by pretreatment with immune serum in a dose dependent manner. Cytokine gene expression was coincidentally suppressed, with the exception of IL-8, by pretreatment with immune serum.

Conclusions: The predominant lineage of *S. aureus* isolated from bovine mastitis efficiently expressed LukM/F, and its exosecretions caused inflammation both in vitro and in vivo. We further suggested the possible beneficial effect of humoral immunity against exosecretions, including leukocidins, to support the host defense mechanisms during bovine mastitis. Further studies are needed to assess the expression of leukocidins in the bovine udder and to characterize their pathological role in mastitis.

Safety of Mucosiffa administered to pregnant dairy cow

Amandine Bibard¹ Mathieu Chevrier¹ Virginie Gay¹ Pascal Hudelet¹ Sylvain Goutebroze¹ Mathieu Chevalier¹

¹Merial, Lyon, France

Objectives: Transplacental infection of the foetus during the first trimester of gestation by a non-cytopathogenic biotype of BVDV has been shown to induce reproductive disorders (embryonic resorption, abortion) as well as provide the potential for the generation of Permanently Infected calves (PI).

This study was carried out to demonstrate the safety of a high dose of MUCOSIFFA (live attenuated vaccine against BVDV) when administered to pregnant dairy cows and heifers representing all stages of gestation. The study design used is in line with that recommended by the European Pharmacopoeia.

Materials and Methods: The study was a blinded, randomized and negative controlled trial. 82 pregnant females (cows and heifers) representing all trimesters of gestation were included, with vaccinates and controls equally represented in each trimester. There were 30 first trimester cases, ranging from 30-120 days in calf, 28 second trimester cases ranging from 121-200 days and 24 third trimester cases which were all >200 days in calf. The vaccinates each received a single administration of twice the maximum release dose of the vaccine in many countries (i.e. receiving 6.3 log₁₀ CCID₅₀ per 2 mL dose).

The potential safety of the vaccine was evaluated by monitoring the number of successful calvings, rectal temperatures, local and systemic reactions as well as milk production. The health and BVDV status of the offspring were also monitored for 2 weeks post-calving.

Results: Both the vaccinate and control groups recorded 95% of successful gestations (78/82 cows, producing 83 calves). Overall, 82 out of the 83 calves (99%) were born in good health, with one calf from a control animal dying within two days of calving. None of the calves were detected as PI.

There were no local or systemic reactions observed following the vaccinations. None of the animals in the study recorded a temperature above 39.1°C during the monitoring periods.

Milk production (monitored daily one week before and one week after vaccination) was recorded daily by a milking robot (De Laval). No statistical difference between vaccinated and control animals was recorded (ANCOVA, p=0.151).

Conclusions: There was no observable negative effect of the vaccine on the reproductive performance of the vaccinated cows and heifers and similarly no observable negative effect on the health status of the calves born from vaccinated animals. The safety of a high dose (6.3 log₁₀ CCID₅₀) MUCOSIFFA administered once during any stage of gestation was confirmed for the vaccinated cows and for their foetuses.

Identification of candidate protein biomarkers for BPI3V diagnosis using an in vitro infection model

Darren W. Gray¹ Simon Doherty² Michael D. Welsh² Mark H. Mooney¹

¹Institute for Global Food Security, Queen's University Belfast, ²Agri-Food and Biosciences Institute, Belfast, United Kingdom

Objectives: The viral pathogen Bovine Parainfluenza Type 3 Virus (BPI3V) of the Bovine Respiratory Disease complex often manifests in an asymptomatic infection, but causes respiratory tract damage, suppressing innate and adaptive immune responses, facilitating proliferation of endogenous opportunistic pathogenic bacteria. Routine BPI3V diagnosis is performed using ELISA, however, positive antibody response does not indicate damaged respiratory tissue or active infection. This study aimed to apply an in vitro biomarker screening approach to identify markers of BPI3V infection for diagnosis of active infection in vivo.

Materials and Methods: Foetal Calf Lung (FCL) fibroblasts were infected with BPI3V at a multiplicity of infection of 10 for 1h and washed with GMEM. 2D Gel Electrophoresis was performed using lysates prepared from BPI3V-infected and mock-infected FCL cells at 0h, 24h and 48h post-infection (p.i.) to identify potential diagnostic markers of BPI3V infection in vivo. The presence of in vitro selected markers was investigated in the blood of BPI3V infected animals using targeted multiple reaction monitoring (MRM) ultra-performance-liquid-chromatography tandem-mass-spectrometry (UPLC-MS/MS). All animal studies were carried out in accordance with the UK Animals (Scientific Procedures) Act 1986 and with the approval of the AFBI Ethical Review Committee. 12 male Holstein Friesian calves aged between 20 and 25 weeks were divided into two cohorts (n=6) designated as either non-vaccinated or vaccinated study groups. Vaccinated group animals were treated with Pfizer Rispoval® PI3+RSV intranasal vaccine as per manufacturer's instructions, and non-vaccinated group animals with empty poly(lactico-glycolic) acid (PLGA) nanoparticles. Plasma taken from vaccinated and non-vaccinated BPI3V challenged animals at day 0 and days 1, 2, 5, 6, 14 and 20 post-challenge (post-BPI3V) was subjected to tryptic digestion and MRM UPLC-MS/MS analysis for the quantification of unique peptides corresponding to in vitro selected protein biomarkers.

Results: The levels of 35 proteins were found to be significantly altered in FCL cells as a result of BPI3V infection. BPI3V induced alterations to the intracellular proteome of respiratory FCL fibroblasts differed to that typically observed in A549 respiratory epithelial cells (apoptotic), resulting in elevated host-proteins associated with mRNA translation, protein translation, post-translational modification and cellular protein trafficking. Phosphoprotein P, T-complex protein 1 subunit-theta and 14-3-3 protein, found to be significantly accumulated within BPI3V infected FCL cells in vitro, were selected as potential diagnostic markers of BPI3V in vivo infection. Using targeted MRM UPLC-MS/MS, proteotypic peptides for Phosphoprotein P and T-complex protein subunit theta were quantified in plasma at days 0, 1, 2, 5, 6, 14 and 20 post-BPIV-3 challenge in vaccinated or non-vaccinated study groups. However, no peptides corresponding to 14-3-3 protein theta were detected in plasma. Unique peptides for phosphoprotein P and T-complex protein 1 subunit theta were found to be significantly (p<0.05) up-regulated at day 5 post-BPI3V in non-vaccinated animals compared to vaccinated animals at the same stage. Plasma levels of Phosphoprotein P were found to increase significantly (p<0.05) from day 1 to day 5 post-BPI3V in non-vaccinated animals. A significant increase in the levels of T-complex protein 1 subunit theta was observed from day 0 to 20 post-BPI3V in plasma of vaccinated animals.

Conclusions: This study demonstrated that proteomic analysis of BPI3V infection in vitro is capable of selecting markers for in vivo BPI3V diagnosis. Viral (Phosphoprotein P) and host-proteins (T-complex protein 1 subunit theta) accumulated intracellularly at the latter stages of infection are released into the circulating bio-fluids, with elevated levels occurring in non-vaccinated BPI3V challenged animals at periods associated with peak virus titre. Compared to serological ELISA,

assessment of such markers released from infected cells or diseased tissue would provide increased information on the health status of serologically positive animals.

Immunology/Vaccinology

P02-002-139

LPS and the NLRP3 inflammasome activator nigericin drive enhanced IL-1 β expression in bovine uterine endometrial cells

Paul Kelly¹*Kieran G. Meade²Cliona O'Farrelly¹

¹Comparative Immunology Research Group, School of Biochemistry and Immunology, Trinity Biomedical Sciences Institute, Trinity College Dublin, Dublin, ²Animal and Bioscience Research Department, Animal and Grassland Research and Innovation Centre, Teagasc, Grange, Co. Meath, Ireland

Objectives: Postpartum bacterial infection of the uterus occurs in all cows, resulting in an inflammatory response associated with healthy involution. However, 30% of cows will develop endometritis, a period of pathological uterine inflammation, with consequences for fertility. Little is known about this transition to pathological inflammation. Here we propose a critical role for endometrial cells in mediating this switch and hypothesize that regulation of inflammasome activation is key. The aim of this study is to investigate the role of inflammasome activated IL-1 β (along with other members of the IL-1 family, namely IL-1 α /IL-18) in uterine inflammation

Materials and Methods: Bovine endometrial tissue was isolated from non-pregnant bovine uteri at stage I of the oestrus cycle, immediately post-mortem. Epithelial and stromal cells were isolated from the uterine horn ipsilateral to the corpus luteum. Alternatively, 8mm biopsy punches were taken for explant culture. Pure populations of cells were confirmed based on morphology and on positive staining for cytokeratin (epithelial) and vimentin (stromal). Absence of CD45⁺ immune cell contamination was confirmed using PCR. Structural integrity and viability of the explant cultures was investigated using histology and by measuring LDH activity in the culture supernatants. To investigate IL-1 production, explant and cell cultures were stimulated with LPS for 3, 6, 12 and 24 hours, followed by nigericin (an inflammasome stimulator) for 1 hour. Levels of IL-1 α , IL-1 β and IL-18 mRNA were measured using qRT-PCR and protein levels of IL-1 β were measured using an ELISA.

Results: Cell isolations (n=6) yielded an average of 1.2×10^6 cells/uterine horn. Cell populations were ~90% pure based on morphology and positive staining for vimentin (stromal) and cytokeratin (epithelial). Histological sections of explant cultures showed normal tissue architecture and no significant differences were observed in LDH activity between control and LPS stimulations (n=7). Stimulation of epithelial and stromal cells (n=6) indicate that bovine endometrial cells produce IL-1 α and IL-1 β in a time dependent manner, with mRNA levels peaking after 6 hours. Levels of IL-1 α mRNA were higher in stromal cells (mean fold change=99.5) than in epithelial cells (mean fold change=1.2) at 6 hours, with IL-1 α mRNA levels in the explant cultures (n=7; mean fold change=3.5) remaining close to the levels seen in the epithelial cells at 6 hours. Similarly, levels of IL-1 β mRNA were significantly higher in stromal cells (mean fold change=86.9, p=0.0062) than in epithelial cells (mean fold change=1.7) at 6 hours, with IL-1 β mRNA levels in the explant cultures (n=7; mean fold change=1.6) closely mirroring those of the epithelial cell cultures at 6 hours. This was verified at a protein level using an ELISA, with nigericin required for protein production. In

contrast, the expression of IL-18 mRNA was not induced in response to LPS and nigericin but was found to be constitutively expressed across all cultures and time-points.

Conclusions: This is the first study to show a novel role for the inflammasome mediated IL-1 β cytokine in the bovine endometrium. The differing levels of IL-1 α and IL-1 β produced by epithelial and stromal cells suggests a principal role for the stromal cells in the orchestration of the inflammatory immune response. On-going work will aim to examine the anti-inflammatory potential of these cells and will also aim to utilise inflammasome inhibitors to characterise the pathways mediating IL1 β production. Shedding light on the mechanisms regulating inflammation will ultimately lead to identifying novel routes to therapeutic intervention for endometritis

Diathelic immunization of heifers against E.coli improves responsiveness to experimental mastitis in early lactation

Vincent Herry¹*Pierre Germon²Florence Gilbert²Guillaume Tabouret³Gilles Foucras¹Pascal Rainard²

¹INP-ENVT, University of Toulouse, Toulouse, ²ISP, INRA, Nouzilly, ³INP-ENVT/INRA, University of Toulouse, Toulouse, France

Objectives: Escherichia coli is a major causal agent of mastitis that impacts in multiple ways on food security, productivity, dairy cow health and welfare. Some vaccines against mastitis are available although these are not widely licensed or have limited efficacy. For the purpose of improving mastitis control and of identifying T cell-associated determinants of protective immune responses, we evaluated the immune response and results upon challenge obtained after immunization against E. coli through different routes. Our objective is to favor a Th1/Th17 cell-mediated immunity to improve neutrophil recruitment and clearance of bacterial infections.

Materials and Methods: Holstein heifers were bred together from the age of 14 months until the end of the experiment. Two groups of six heifers each received one intramuscular injection of heat-killed E. coli P4 bacteria (2×10^9 colony-forming units, CFU) in MontanideTM adjuvant three months before calving. Two months later, a boost injection with the same preparation was done by intramuscular (IM) route in the IM immunized group, while the other group (IMM immunized group) received a diathelic injection of ultracentrifugated E. coli P4 culture supernatant (50 μ g proteins). Adjuvant only was administered to six control cows by the IM route. Approximately 50 days after parturition, all cattle were challenged with live P4 bacteria (10^3 CFU in total) through the teat canal of one healthy quarter (somatic cell count SCC<50,000 cells/mL). Clinical evaluation, in addition to laboratory testing, was performed during two weeks upon inoculation.

Results: Results showed strong antibody and cell-associated immune responses in the blood of immunized cattle, indicating that the immunization resulted in Th1/17 priming. Upon homologous challenge, clinical signs at the acute phase (12 hours pi) are less severe in the immunized cattle compared to the controls (3.0 vs 5.2 AU, Two-way ANOVA, p-value<0.05); IMM immunized cattle recover more rapidly thereafter (Cumulative clinical score, Mann-Whitney test, p<0.05). The reduction of milk production was significantly lower in the immunized groups (Two-way ANOVA, p<0.001), indicating that immunization was successful at reducing milk losses. No difference of local inflammation

was noticed in immunized cows, but the mammary inflammation in the IM immunized group tended to persist longer than in the control cows. Leucodepletion in the immunized groups was also significantly lower. Furthermore, the time required for bacterial clearance was half in immunized cows compared to the controls, although SCC were not significantly different amongst the groups over the mastitis course.

Conclusions: These results indicate that priming of Th1/Th17 immunity against *E. coli* improves significantly the conditions against clinical mastitis associated with this pathogen. Moreover, afforded protection is improved when specific cells are recruited locally through a mammary recall. Further studies are needed to determine mechanisms affording protection against Gram-negative mastitis, and the advantages and mechanisms of locally-administered vaccines over systemic immunization.

P02-002-141

Effect of injectable trace minerals on the immune response to bacterial antigens after administration of an attenuated-live bacterin in dairy calves

Roberto A. Palomares¹·David J. Hurley¹Fallon Moliere¹Lourens L. Havenga²Amelia R. Woolums³Sarah Clifton¹Alex Sigmund¹Carly E. Barber¹Madison L. Berger⁴Madison J. Clark⁵Melanie Fratto¹

¹Population health, University of Georgia, Athens, ²Multimin USA, Multimin USA, Colorado, ³Clinical Sciences, Mississippi State University, Mississippi State, ⁴College of Veterinary Medicine, University of Florida, Gainesville, ⁵College of Veterinary Medicine, North Carolina State University, North Carolina, United States

Objectives: In a previous report we showed that injectable trace minerals (ITM) improved the humoral and cell mediated immune (CMI) responses to viruses involved in the bovine respiratory disease complex, following administration of a modified-live virus (MLV) vaccine in dairy calves (Palomares et al., 2015; AABP conference). The objective of this study was to evaluate the effect of an ITM supplement containing zinc, manganese, selenium, and copper on the humoral and cell mediated immune (CMI) responses to individual vaccine antigens in dairy calves receiving an attenuated-live bacterin containing *Pasteurella multocida* and *Mannheimia haemolytica*.

Materials and Methods: A total of thirty dairy calves (3 months of age) were administered 2 mL of an attenuated-live *M. haemolytica* and *P. multocida* bacterin (Once PMH®, Merck Animal Health) subcutaneously (SQ). Calves also received 2 mL of a 5-way MLV vaccine containing BHV1, BVDV1 & 2, BRSV, PI3V (Express 5®, Boehringer Ingelheim, Vetmedica), and were randomly assigned to 1 of 2 groups: (1) Administration of ITM SQ (1 mL/100 lb BW, ITM; Multimin 90, Fort Collins, CO; n = 15) or (2) Injection of sterile saline SQ (2 mL, Control; n = 15). Administration of ITM provided 15, 60, 10 and 5 mg/mL of Cu, Zn, Mn and Se. Three weeks after initial vaccination, calves received a booster of 2 mL of the attenuated-live bacterin and 2 mL of the 5-way MLV vaccine SQ. Concurrently with the vaccine booster, a second administration of injectable trace minerals or sterile saline SQ was given to calves in ITM and control group, respectively. Blood samples were collected into tubes with and without acid citrate dextrose to obtain whole blood and serum respectively on days 0, 7, 14, 21, 28, 42, 56, and 90 relative to prime vaccination for antibody titer determination, antigen-induced in vitro IFN-γ production by peripheral blood mononuclear cell (PBMC), and antigen-induced PBMC proliferation. Statistical analysis was performed

using the Statistical Analysis System (SAS®). Non-parametric analysis was applied using Mann-Whitney U and Friedman tests for comparisons between treatment groups and over time, respectively. For all analyses values of P < 0.05 were considered significant.

Results: A strong humoral immune response to *M. haemolytica* or *P. multocida* was not observed after the primary vaccination. However, both the ITM and control group had a significantly increased antibody response to both antigens after booster vaccination. Between days 21 and 56, the calves that received ITM had a higher antibody titers (and higher rate of increase) to *M. haemolytica* compared to the control group. Significant differences were not observed in the antibody titers to *P. multocida* between groups. Only calves treated with ITM showed an augmented PBMC proliferation response upon *P. multocida* stimulation on day 21 after prime vaccination compared to day 0 (P =0.03). On the other hand, control calves did not show any significant change in CMI to *P. multocida* over time. Significant differences were not found in the production of IFN-γ by PBMC upon stimulation with *P. multocida* between calves treated or not with ITM concurrently with bacterin administration.

Conclusions: In conclusion, administration of ITM concurrently with vaccination in dairy calves resulted in increased fold change in antibody titer to *M. haemolytica* (between days 21 and 56 after primary vaccination) compared to the control group and an augmented PBMC proliferation upon stimulation with *P. multocida* on day 21 compared to day 0. ITM might represent a promising tool to enhance the immune response to attenuated-live bacterin in an attempt to prevent respiratory disease in cattle.

Protection against bovine respiratory syncytial virus provided by maternally derived antibodies from cows immunized with an inactivated vaccine

Herve Cassard¹·Antoine Cuquemelle²Maxence Delverdier²Charlotte Foret³Birgit Makoschey⁴Gilles Meyer¹

¹Ruminant section, Department of Livestock and Products – Veterinary Public Health, ²INP-ENVT College of Veterinary Medicine of Toulouse - France, ³UMR1225 IHAP, INRA-ENVT, Toulouse, France, ⁴MSD Animal Health/Intervet International, Boxmeer, Netherlands

Objectives: Our study aimed to assess the degree of clinical and virological protection against BRSV conferred to calves by maternally derived antibodies (MDA) contained in the colostrum of cows immunized with an inactivated BRSV-PI3-Mannheimia haemolytica vaccine (Bovilis® Bovigrip, MSD Animal Health) during late gestation.

Materials and Methods: Thirty-two dairy cows, BRSV-seronegative or with low BRSV-antibody titers, were separated into 2 groups. Sixteen cows received two doses of an inactivated BRSV-PI3-M. haemolytica vaccine (Bovilis® Bovigrip, MSD Animal Health), 8 and 4 weeks before their expecting calving dates, whereas the other 16 cows were not vaccinated. Colostrum from each cow was collected at calving, tested for BRSV-antibodies (ELISA and seroneutralisation (SN)), and stored at -20°C. Two months later, 28 neonate dairy calves were immediately separated from their dam after birth and fed colostrum (10% of body weight within the first 6 hours) either from the vaccinated (n=14, vaccine group) or from the non-vaccinated cows (n=14, control group). Quality of the passive transfer of the BRSV-specific MDA was assessed by ELISA and SN at 1, 7, 14 and 21 days after birth. At 22 ± 3 days after birth (D0), all calves were inoculated by the intranasal and intratracheal routes with

the BRSV 3761 strain (2×10^5 TCID₅₀/calf). Clinical examination was done daily from D-3 to D15. Nasal swabs were collected every 48 h from D-2 to D16, to monitor BRSV excretion by RT-qPCR (Taqvet BRSV, LifeTechnologies). Bronchoalveolar lavages (BAL) were performed at D0, D3, D6, D10 and D16 (5 calves/group) to quantify BRSV loads in the lower respiratory tract (RT-qPCR) and to study the host response by transcriptomic analysis of 60 bovine genes involved in inflammatory response (real time PCR Fluidigm technology). Calves were euthanized at D7 (5 calves/group) and D16 (17 calves) to assess gross and histological lung lesions.

Results: A strong BRSV antibody response was detected in the vaccinated cows by ELISA and SN although the increase of SN antibodies was obvious only after the second immunization. This resulted in high titres of BRSV ELISA and, to a lesser extent, SN antibodies in the colostrum of immunized cows and therefore in calves fed these colostrums. On the other hand, calves from the control group remained seronegative until the challenge. After the challenge, all calves from the control group showed clinical signs of respiratory disease. In contrast, 35.7 % (5/14) of calves of the vaccine group remained healthy and none had severe respiratory clinical signs. The mean clinical scores from D7 to D11 and the accumulative clinical score were significantly different between the two groups. Interestingly, approximately at the same period (D6 to D16), the quantities of BRSV-RNA detected in the BAL from calves of the vaccine group were lower than in the control group, suggesting that MDA partially blocked the BRSV replication in the lungs. On the other hand, BRSV-RNAs were detected in nasal swabs of all infected calves from D2 to D15 (peak at D6) with no significant differences between the two groups, suggesting that MDA didn't interfere with virus replication in nasal cavities. Gross and histological lung lesions in calves of the vaccine group tended to be less extensive and less severe at D16 than those of the control group but the differences were not significant. Finally, differences were observed between the two groups in the transcription levels of major inflammatory bovine genes.

Conclusions: MDA of cows vaccinated with Bovilis® Bovigrip conferred a partial but significant clinical protection to calves during the first 3 weeks of life, especially against severe BRSV disease. However, the calves fed the colostrum of vaccinated cows were not protected against BRSV replication in their nasal cavities. These results suggest that vaccination of BRSV-seronegative pregnant cows may be a strategy to reduce clinical consequences of BRSV infection at a herd-level, provided that a colostrum management program allowing an effective passive transfer of immunity in calves is implemented.

Acute phase protein response in the calves administered with experimental *M. bovis* vaccine

Dariusz Bednarek¹; Katarzyna Dudek¹

¹Department of Cattle and Sheep Diseases, National Veterinary Research Institute, Pulawy, Poland

Objectives: *Mycoplasma bovis* is considered as a causative agent of different cattle disorders such as bronchopneumonia, arthritis, mastitis, keratoconjunctivitis, otitis and reproductive problems. A high resistance of majority isolates of the bacteria to veterinary-use antibiotics complicates the effective control of *M. bovis* infection. Moreover, there is still a lack of commercial vaccines in Europe, whereas data about such vaccines available in the United States is limited. The aim of the study was to

evaluate the acute phase protein response in the calves administered with experimental *M. bovis* vaccine.

Materials and Methods: Twelve clinically healthy female calves were used in the study. The calves were divided into two groups of six calves: experimental and control. The experimental calves were administered subcutaneously with the inactivated experimental vaccine composed of the Polish field *M. bovis* strain and a combination of saponin (Sigma, Poole) and Lydium-KLP™ (Nika, Health Products). Control calves were injected with sterile phosphate buffered saline by the same route. The blood samples were collected on days 0, 1-7, and then in 7 day intervals up to the end of the study at the 84th day of observation. Serum concentrations of selected acute phase proteins such as haptoglobin (Hp) and serum amyloid A (SAA) were determined using two different ELISA kits manufactured by Tridelta Development Ltd.

Results: In response to the experimental vaccine administration a distinct increase in the Hp concentration was observed at days one and two when compared to the control. During other days of observation the Hp values fell to the nought. On the other hand the calf vaccination caused above a six-times increase in the SAA concentration at day one in a comparison with the control. Distinct increased values of this parameter were registered up to day 6. However a renewed visible rise in the SAA concentration was observed at days 49, 56 and 84 post vaccination. During other days of observation the SAA concentration was close to the control values or slightly increased.

Conclusions: The calf administration of the experimental vaccine composed of the Polish field strain of *M. bovis* combined with saponin and Lydium-KLP™ caused a stimulation of acute phase response manifested with a significant increase in the concentration of Hp and SAA, indicatory acute phase proteins for cattle.

Immunology/Vaccinology

P02-002-145

Subcutaneous ischiorectal fossa injection: serological, colostrum immunity and tissue reactivity in rota, corona and *E. coli* F5 (K99) vaccinated cows

J. Moffat¹; K. Gloyne²; R. Smith³

¹MSD Animal Health, Wellington, ²Vet Ent Otorohanga, Otorohanga, ³Taranaki Vet Services, Patea, New Zealand

Objectives: Most labels in production animals indicate vaccination in the anterior third of the neck. In New Zealand (NZ) dairy, access to the neck is impractical and dangerous. Alternative injection sites meeting meat processing requirements is needed. Objective of this multi-site, parallel-group randomised non-inferiority study was to compare the immune response, measured by anti-rotaviral antibodies, and injection site reactivity, between cows vaccinated i.m. in the anterior third of the neck (IM) with cows injected s.c. in the ischiorectal fossa (IRF) using an oil emulsion vaccine containing inactivated rotavirus, corona virus and *E. coli* F5 (K99).

Materials and Methods: 120 healthy Friesian, Jersey and Friesian x Jersey cows, from two seasonally (spring) calving commercial dairy farms in the North Island of NZ, vaccinated with Rotavec Corona® (MSD Animal Health, NZ) in the previous calving season, were enrolled. On each farm, half the cows were randomly assigned to either the IM or IRF injection site and were grazed together on ryegrass/clover pasture until they calved. Rotaviral titres were determined in sera on days 0, 7, and 21 and immediately post-calving in sera and colostrum. Rotaviral

specific antibodies were quantified by virus neutralisation using a bovine rotavirus isolate (molecular typed as G6P5). Injection sites were scored on Days 0, 7, and 21. The primary outcome, colostral rotaviral antibody geometric mean ratio (GMR) of the IRF and intramuscular group, and its lower one-sided 95% CI, was estimated using linear regression with treatment group as the predictor, conditioned on variables considered a priori to be influential (i.e. farm, breed, age, and pre-vaccination serum titre). Model assumptions were evaluated by examination of residuals and generation of Cook's D values. Sensitivity analyses were conducted by removal of potential influential observations. Non-inferiority was declared if the lower limit of the 1-sided 95%CI of the GMR was above the non-inferiority margin 0.63. This margin corresponds to a difference of about two thirds of a twofold dilution in a serial dilution assay (USDA-vet service memorandum, 2007).

Results: The distribution, and geometric mean titre (GMT), of serum and colostral rotaviral antibody titres of cows vaccinated subcutaneously in the IRF was very similar to that of cows injected by the standard IM route. The lower bound of the GMR was 0.68, demonstrating statistically significant non-inferiority. No systemic adverse events were associated with either vaccination site. Thirteen of the fifteen largest lesions were observed in cattle vaccinated in the neck; but there was no evidence that the median volume was different between the different injection sites.

Conclusions: Vaccination with an oil adjuvanted, inactivated rotavirus, corona virus and E.coli F5 (K99) subcutaneously in the IRF is as effective as intramuscularly injection in the neck. This gives NZ vets the confidence to prescribe an alternative injection site and hence reduces the risk to farmers and themselves of injury during routine vaccination.

Does BVD vaccination of recently weaned pasture-fed beef cattle prevent weight loss when exposed to persistently infected cattle?

J. Moffat¹, S. Bruere²

¹MSD Animal Health, Wellington, ²Chapel St Vets, Masterton, New Zealand

Objectives: Bovine Viral Diarrhoea virus (BVDv) commonly infects New Zealand (NZ) cattle and can cause significant production loss; especially reproductive failure. Although not considered as important, ill-thrift associated with transient infection may affect growth. The primary objective of this study was to compare the growth rate of vaccinated vs. non-vaccinated calves following exposure to persistently infected (PI) cattle.

Materials and Methods: The study population, in this single-site, randomised parallel group challenge field trial, was 80 weaned, mixed-gender, spring-born (August, 2013) Angus-x cattle from a BVD seronegative herd on a farm in the southern Wairarapa (North Island, NZ). Assuming a standard deviation (SD) of 100g/day (and alpha 0.05 and beta 0.80) the minimum detectable difference in average daily gain (ADG) was estimated as 63g/day. In May 2014 the cattle were randomised (blocked by weight and gender), into a non-vaccinated control or a vaccinated group (n=40/group). Calves were vaccinated with an inactivated Type I BVD vaccine (Bovilis® BVD, MSD Animal Health, NZ) on days 0 (V1) and 28 (V2). Six PI (BVD Type I) calves were introduced 14 days after V2 (day 42); they were initially yarded with the mob for 4 hours, and then remained within the mob for the remainder (70 days) of the study. The cattle were run as one mob on a brassica

crop with access to a run-off pasture and ad-lib water and meadow hay. A viral neutralisation test (VNT) was used to measure BVDv specific antibody on days 0, 42, 56, 70, and 84. The calves were weighed days 0, 42, 56, 70, 84, 98 and 112. ADG between PI introduction and day 98 was modelled using linear regression with the fixed effect of vaccination adjusted for baseline weight and gender (NB: data from day 112 was excluded due to a radical change in diet 24 hours prior to being weighed).

Results: At enrolment, mean weight was 218 vs 230kg for females and males resp., similar for the 2 treatment groups, and all calves were BVDv antibody negative (titres <1:2). All vaccinated cattle had titres 14 d after their 2nd vaccination, (1:16 to 1:512) with a median IQR of 1:64. Within 14 d of introduction of the PIs, 44% (17/39) of the non-vaccinated cattle seroconverted. At day 70 all had seroconverted. Assuming a ≥ 4x increase was an amnestic response, 15% (6/39), 67% (26/39), and 97% (38/39) responded < 14, 28 and 42 d resp., of PI introduction. The difference (%) in serological response of groups (14 d risk difference (RD) is 28% [95%CI 9 to 47%, P_{chi2} = 0.0063] and the 28 d RD is 33% [19 to 48%, P_{chi2} = 0.0001]). Given exposure risk to PIs was assumed to be equal for all, differences suggest a different immunological response. Moreover, the geometric mean titre [95%CI] in the vaccinated cattle (34,000, [24,300 to 47,800]) was 15.2x greater ([7.4 to 24.4], P = <0.0005) than the non-vaccinated (2,200, [1,600 to 3,200]) at the last blood test 42 d after PI introduction. This shows a marked amnestic response in the vaccinated cattle. After vaccination and prior to challenge the 2 groups had equal ADG indicating no adverse event on growth (Control, 980 [916 to 1044] g/day vs vaccinated, 1011 [949 to 1072]g/day; a difference of 30 [-57 to 118]g/day, P = 0.49). Vaccinated cattle, adjusted for gender and starting weigh, had on average a 56.8g/d greater ADG over the 56 d after the PI cattle introduction. This difference was almost significant (95%CI -3.0 to 116.6g/day, P= 0.062).

Conclusions: BVDv rapidly spread through the study population. Vaccinated cattle showed a marked difference in the immune response compared with non-vaccinated cattle. The 56.8g/day greater ADG of the vaccinated calves, is suggestive of a protective vaccine effect; however given the greater variability in the study population than was anticipated (i.e. SD of 133g/day vs. assumed 100g/day) the study had insufficient power to discriminate this difference with 95 % confidence. This small study indicates transient BVDv infection may affect growth in pasture-fed cattle and vaccination may reduce this effect, however further studies are required.

Immunology/Vaccinology

P02-002-147

Puerperal and milk shedding of C. burnetii are associated with different immune profiles

Jens Boettcher¹, Magdalena Schumacher¹, Britta Janowitz¹, Benjamin Motsch¹, Sylvia Keilholz¹, Michaela Alex¹, Daniel Mehne¹

¹Bavarian Animal Health Service, 85586 Poing, Germany

Objectives: C. burnetii (Cb) causes Q fever in humans and Coxiellosis in animals. Serological diagnosis in human medicine relies on two antigens: Phase I (PhI) and Phase II (PhII). PhII-antibodies are detected early after infection, high-level PhI-titers are indicating a chronic course of infection. Regarding dairy cows repeated detection of Cb in milk was associated with increased PhI-titers, too. In this study we assessed immune profiles (phase-specific antibody, IFN-γ-responses) of cows with different Cb-shedding histories before and after vaccination with an inactivated Cb vaccine (Coxevac).

Materials and Methods: Blood samples were tested for phase-specific antibodies (ELISA) and Cb-specific interferon- γ (IFN- γ) reactivity by an IFN- γ -recall assay. Cows in an Cb-infected herd were repeatedly tested for milk (MS) and puerperal shedding (PS) by quantitative PCR over a period of 2 ½ years prior to vaccination. Subsequently, cows were allocated to the following groups: PS+/MS+ (n=16), PS-/MS+ (n=36), PS+/MS- (n=17) and non-shedders (NonS; n=37). A group of primiparous cows that had been vaccinated prior to first breeding (Coxevac) was included as a 5th group (H/Vacc; n=11). Shedding within the last 6 months or more than 6 months prior to testing was included as an additional variable. After vaccination the following groups were compared: cows shedding Cb in milk (MS+/PS-/+), shedding Cb at calving (PS+/MS-), non-shedders with antibodies (NonS/Ab+) and seronegative non-shedders/IFN- γ -negative (neg).

Results: Prior to vaccination groups PS+/MS+ and PS-/MS+ showed strong PhI- and PhII-titers. PhII-titers and low/absent PhI-titers were observed in groups NonS and PS+/MS-. An inverse reactivity was detected by IFN- γ -recall assay i.e. higher IFN- γ -reactivity was found in PS+/MS- compared to PS+/MS+ and PS-/MS+. If the last shedding occurred more than 6 months ago a shift in reactivity was observed: IFN- γ -reactivity (PS+/MS+; PS-/MS+, PS+/MS-) was increased and PhI-titers (PS-/MS+) decreased.

After vaccination both PhI and PhII-titers increased except for the negative group and H/Vacc, in these animals only PhII-titers were detected. Groups PS+/MS- and NonS/ab+ showed a strong IFN- γ -response already after first vaccination. It might be explained by a booster of preexisting immunity. In contrast, IFN- γ -response in group MS+/PS-/+ developed slowly and even after 2nd vaccination some animals failed to develop an IFN- γ -response.

Conclusions: Puerperal shedding of Cb was associated with a favorable immune response before and after vaccination. Shedding of Cb in milk - irrespective of puerperal shedding - was associated in some animals with an inappropriate immune response even after vaccination. This failure might be related to a chronic course of infection. Currently, we are using PhI-titers >100 as a suitable marker of chronic Cb-shedding in milk, which is confirmed by qPCR.

PhII-titers in absence of PhI-titers are regarded as an indicator of acute infection in humans. This is principally true for cattle, too, but it was also observed after resolution of infection or vaccination.

Comments: This study was financially supported by the Free State of Bavaria and the Bavarian Joint Founding Scheme for the Control and Eradication of contagious Livestock Diseases.

Immunology/Vaccinology

P02-002-148

Impact of oral meloxicam and transport on CMI and humoral immunity in feedlot steers receiving a MLV BVDV booster vaccination at arrival

Nicholas Van Engen¹, Johann Coetzee¹, James Roth², Ratre Platteau², Terry Engelken¹

¹VDPAM, ²VMPM, Iowa State University, Ames, United States

Objectives: The objective of this study was to investigate the impact of oral meloxicam (MEL) and long-distance transportation on cell-mediated immunity (CMI) in preconditioned steers receiving a booster vaccination on arrival. We hypothesized that steers treated with MEL at 1 mg/kg body weight 6 hours before night-time transport would be

less immunocompromised on arrival (day 0) and after 7 days, and that CMI following vaccination with a modified live bovine viral diarrhoea virus (BVDV) recall antigen would be increased.

Materials and Methods: Brahman crossbreed steers, 13 to 17 months of age (n=87), were randomly assigned to one of four treatment groups: MEL, transported (MTR) (n=22), MEL, non-transported (MNT) (n=22), lactose placebo, transported (CTR) (n=21), and lactose placebo, non-transported (CNT) (n=22). MTR and CTR steers were transported for approximately 16 hours non-stop on a truck from Mississippi to Iowa (approximately 1,300 km), whereas steers in the MNT and CNT groups remained in Mississippi as non-transported controls. Body weight was measured and jugular blood was collected at -1, 0, and 7 days from all steers at the same time, regardless of location. Multi-parameter flow cytometry (MP-FCM) was used to identify T-cell subsets and detect the expression of three activation markers (CD25 [interleukin (IL)-2 receptor], intracellular interferon-gamma [IFN γ], and IL-4) after *in vitro* stimulation with BVDV recall antigen. Plasma cortisol concentration was measured at days -1, 0, and 7 as a marker of transport-associated stress. Serum antibody titer to BVDV was assessed on day -1 and day 7 post-booster vaccination. Whole-blood samples were analyzed using MP-FCM on days 0 and 7. Results were log transformed and analyzed using a mixed effects model.

Results: Compared with non-transported controls, transport led to an increase in BVDV-induced expression of CD25, IFN γ , and IL-4 in CD4⁺, CD8⁺, and $\gamma\delta$ T-cell subsets (P<0.05). MEL treatment mitigated the transportation-associated increase in CD25 expression by peripheral blood mononuclear cells (PBMCs), CD4⁺, and $\gamma\delta$ T cells. CMI outputs for the MTR group were less than those of the CTR group (P<0.05); however, the MTR and NT groups did not differ (P>0.10). A treatment/transport interaction was noted for the increase in IL-4 expression by CD8⁺ T cells after transport, with a significant difference between the CTR and MTR groups at day 7.

Conclusions: In conclusion, the use of oral MEL prior to transport may have beneficial effects, but further research is needed to validate the effect of MEL treatment on specific T-cell subsets in transported cattle.

IL-1 β overcomes the deficiency in IFN- γ production in calves

Ciaran Harte¹, Kieran Meade², Ed Lavelle³

¹Teagasc/TCD, Dublin, ²Animal and Bioscience Research Department, Animal and Grassland Research and Innovation Centre, Co Meath,

³Trinity College Dublin, Dublin, Ireland

Objectives: Vaccine development has shifted from whole-microorganism based preparations towards subunit-based vaccines which although safer are less immunogenic. A key factor in the efficacy of vaccines is the age of vaccination but the importance of age for adjuvanticity has not been fully resolved. While adjuvant research has traditionally focused on humans and mice, there is a growing demand for new and improved veterinary vaccines. This is particularly important with regard to increasing food production and preventing zoonotic diseases. Therefore, we aimed to address the mode of action and importance of age in adjuvant activation of bovine immunity.

Materials and Methods: Inflammasome and T-cell responses were observed in 5 Friesian calves over a period of 8 months. Each month, bovine peripheral blood mononuclear cells (PBMCs) were isolated

and treated with various doses of ConA, a T-cell mitogen capable of driving T-cell proliferation. Additionally, PBMCs were also treated with a combination of ConA and recombinant IL-1 β . To analyse inflammasome responses in calves from 3-10 months of age, bovine PBMCs were primed with LPS before being treated with an inflammasome stimulating adjuvant, named alum. Following stimulation, supernatants were harvested and tested for cytokines IFN- γ , IL-17, IL-4 and IL-1 β .

Results: While bovine PBMCs from 4 month old calves showed robust secretion of Th2 and Th17-associated cytokines in response to T-cell mitogen stimulation, the ability to produce the Th1-associated cytokine IFN- γ remained subdued until 6 months of age. Interestingly, IL-1 β enhanced secretion of IFN- γ in young calves. Similarly, IL-17 expression was increased in response to IL-1 β , while no enhancement of the Th2 associated cytokine IL-4 was observed. This suggests the potential of IL-1 promoting adjuvants as drivers of bovine Th1 immunity. Having shown that IL-1 β is an important mediator of Th1 and Th17 responses in calves, IL-1 β secretion was assessed over a range of ages. PBMCs from young animals (3-4 months) responded strongly to inflammasome activating adjuvants indicating that there is no age dependent defect in inflammasome activation and further suggesting the potential of adjuvants to drive this pathway as a means to enhance Th1 and Th17 responses in cattle.

Conclusions: This study confirms the selective defect in IFN- γ production by calf PBMCs but for the first time identifies different kinetics with regard to IL-17 secretion. Furthermore it suggests the potential of driving IL-1 β secretion by innate cells through vaccine-adjuvant formulations as a means to boost both IFN- γ and IL-17 secretion.

Efficacy and safety of Zelnote®¹, a novel DNA Immunostimulant, in cattle

Jason Nickell ¹Daniel Keil ¹Terry Settje ¹Kelly Lechtenberg ²Vijayakrishna Singu ²Amelia Woolums ³

¹Bayer Animal Health, Shawnee, KS, ²Midwest Veterinary Services, Oakland, NE, ³Mississippi State University, Starkville, MS, United States

Objectives: Bovine respiratory disease (BRD) negatively impacts the beef and dairy industries. Leveraging the innate immune system may improve the health of cattle at risk for BRD. The objectives of this series of studies were to evaluate the efficacy (Studies 1 and 2) and safety (Studies 3 and 4) of a novel DNA Immunostimulant (Zelnote®).

Materials and Methods: The DNA Immunostimulant was administered concurrently with (Study 1) or 24 hours after (Study 2) a multi-drug resistant Mannheimia haemolytica (Mh) challenge. Holstein steers (3-4 months of age; N=32/treatment, Study 1; N=40/treatment, Study 2) received the DNA Immunostimulant or a negative control on Day 0 (Study 1) or Day 1 (Study 2). Calves were challenged (intratracheally) with 60 mL of Mh (107 CFUs/mL, Study 1; 108 CFUs/mL, Study 2) on Day 0 and clinically observed to Day 5. Lung scores were obtained at the time of premature death or after necropsy on Day 5.

Twenty healthy Holstein bulls, 3-4 months of age, were enrolled in Study 3. On Day 0, the DNA Immunostimulant and the negative control was administered on opposite sides of the neck, intramuscularly, in each calf (each calf served as its own control). Injection site palpation occurred on Days 0-7. All calves were clinically observed for either 21 (N=10)

or 28 (N=10) days and subsequently necropsied. Tissue sections were harvested from both sides of each calf's neck (corresponding to each site of injection) and evaluated for evidence of gross and histopathological changes. Tissue specimens were examined by a board-certified veterinary pathologist.

In Study 4, 612 healthy, post-weaned, commercial calves \geq 3 months, were enrolled and the DNA Immunostimulant was administered, intramuscularly, to each calf on Day 0. Injection sites were palpated on Day 3. All calves were clinically observed for 21 days and were eligible for commerce at study completion.

Results: In this Mh model, the DNA Immunostimulant was observed to mitigate lung pathology by 40.3% (95% confidence interval [CI]; 13.9%, 65.3%) and 36% (95% CI; 3%, 64%) in Studies 1 and 2, respectively, compared to the negative control. In Study 2, cattle administered the DNA Immunostimulant on Day 1 displayed a significant reduction in mortality (p=0.0394) compared to cattle receiving the negative control on Day 1.

In Study 3, the DNA Immunostimulant was shown to induce no adverse reactions, relative to the negative control, at the injection site (both grossly and histopathologically). In Study 4, no adverse events were observed among large populations in different field scenarios.

Conclusions: The DNA Immunostimulant demonstrated efficacy by mitigating lung lesions (Studies 1 and 2) and decreasing mortality (Study 2) in this Mh disease model. Studies 3 and 4 display that the DNA Immunostimulant is safe for use in cattle. The DNA Immunostimulant (Zelnote®) is labeled as an aid in the treatment of BRD when administered at the time of, or within 24 hours after, a perceived stressful event. A 21 day meat withdrawal has been established for this product.

Change of blood morphophysiological parameters in calves during vaccination under influence of metabolism stimulator Catosal

Elena Gnatiuk ¹Olexandr Kostyuk ¹Ion Moraru ²Volodymyr Zotsenko ³

¹Bayer, ²Svoe Svizhe, Kiev, ³National Agricultural University, Bila Tserkva, Ukraine

Objectives: This field study demonstrated the peculiarity of calves immunity formation, and changes in morphophysiological blood parameters during vaccination period under the influence of immunomodulating product.

Materials and Methods: 30 calves of 30-day age were divided by the principle of analogues into three groups 10 calves each group. The animals from Group 1 received on Days 0 and 14 inactivated viral-bacterial vaccine against respiratory syncytial infection, parainfluenza-3, virus diarrhoea and pasteurellosis BioBos Respi 4 («Bioveta», Czech Republic) and metabolism stimulator Catosal («Bayer HealthCare LLC», USA), which contains butafosfan and cyanocobalamin. The animals from the Group 2 were treated by vaccine on day 0 on day 14 of experiment. The calves from group 3 were untreated control.

Number of erythrocytes, leucocytes, haemoglobin, haematocrit were estimated before treatment on Day 0 and then on Days 14 and 30. Erythrocytes, leucocytes (including lymphocytes, monocytes, granulocytes), thrombocytes, haemoglobin, haematocrit, mean cell haemoglobin, mean cell haemoglobin concentration were estimated on day 30. Antibodies against respiratory syncytial infection virus level

was determined by EIA method, using diagnostic test-systems of the company IDEXX, CIVTEST on Days 14, 30, 43 and 63.

Results: On Day 30 the blood parameters were higher in the Group 1 than in Group 2 and Control: erythrocytes by 13% and 28,8% ($p<0,05$), haemoglobin by 15% and 23% ($p<0,01$), thrombocytes by 36,3% and 31,8% respectively ($p<0,05$).

There was registered the decrease of leucocyte count on Day 14 at revaccination in Group 2 and in control group by 24,4% and 32,6% comparing to Day 0. On Day 30 leucocyte level in both groups increased, however, it was still below initial range. In Group 1 the animals demonstrated leucocyte count increase within normal range during the whole observation period. On Day 30 leucocyte count in animals from Group 1 was 23% higher the initial amount ($p<0,01$).

The antibodies level in Group 1 was higher than in Group 2 during the whole period of observation: by 2.5 times on Day 14, by 1,9 times on Day 30, by 1,4 times on Day 43 and 1,7 times on Day 63 ($p<0,01$).

Conclusions: Catosal provided immunomodulating effect, securing stable high leucocytes level during the whole observation period, and stimulated nonspecific immune response, which was confirmed by higher level of leucocytes and thrombocytes.

Concomitant administration of vaccine and Catosal stimulated specific immune response by organism, accelerating antibodies production and providing for higher dynamics of antibodies titre increase.

P02-002-153

Vaccination of dairy cows in late gestation: effect on serum and colostrum antibody titers for BRSV and Mannheimia haemolytica.

Bertrand Ridremont¹ Laurent Nouvellon² Vincent Tessier¹ Evelyne Michel³ Sébastien Assié⁴ Jantijn Swinkels^{5,1}

¹MSD Santé Animale, Beaucauzé, ²GIE Synvet, St Aubin du Cormier, ³ISAE, Fougères, ⁴Oniris, Nantes, France, ⁵MSD Animal Health, Madison, United States

Objectives: Vaccination of calves against BRD is overall effective but, in some field situations, i.e. high infectious pressure, early infection in very young calves before active vaccination, this could not be enough to protect them against disease.

The objective of the study was to observe whether vaccination of cows during late gestation with a respiratory vaccine influences levels of serum and colostrum antibodies in the cow and in their calves after colostrum intake.

Materials and Methods: The fieldwork was conducted by local veterinarians during the fall and winter 2013-2014 in Brittany. Two hundred Holstein cows from 13 farms were randomly selected to either vaccination ($n=100$) with antigens of BRSV, PI3 and Mannheimia haemolytica (Bovilis® Bovipast, MSD Animal Health) or no vaccination ($n=100$). Cows were vaccinated according to label; the first dose was injected between 8-6 weeks before expected calving and the second dose between 4-2 weeks before expected calving. Levels of antibody titers were compared between cows in each group and between cows and their calves from both groups raised on the same farms. Seroneutralizing antibody levels of BRSV were measured by a VN test (ISAE). To determine M. haemolytica antibody levels, a validated quantitative ELISA (MSD Animal Health) was used.

Results: After different steps of selection in the database (elimination of couples mainly because of missing data), 189 mother-calf pairs were included in the analysis. One hundred mothers were vaccinated before calving and 89 were not vaccinated. The animals were followed in 13 different herds and in each herd the number of vaccinated and unvaccinated animals ranged from 6-27. The levels of BRSV and Mannheimia haemolytica antibodies measured at the first blood test before vaccination did not differ between vaccinated and non vaccinated cows ($p>0.05$). Following vaccination, specific neutralizing antibody titers of BRSV tended ($p=0.07$) to be higher in colostrum from vaccinated mothers compared to control cows. However these levels were significantly higher ($p=0.01$) in the serum of calves born from vaccinated mothers compared to those from non vaccinated mothers. After vaccination, significantly higher levels of M. haemolytica antibodies ($p<0.001$) were measured in serum of cows, in the colostrum of vaccinated dams and in the serum of calves born from vaccinated cows, always in comparison to the control group.

Conclusions: This field study confirmed that vaccination of cows in late gestation, with a commercial trivalent vaccine increased the levels of serum and colostrum antibodies against 2 major respiratory pathogens. Vaccination of late gestation cows in addition to vaccination of calves, may prevent BRD more effectively, especially in herds either with a high prevalence of BRD in young calves (<3 weeks of age) and/or with high infectious pressure on all types of cattle present in the farms. Further research is needed to evaluate the return on investment of such vaccination programme.

Immunology/Vaccinology

P02-002-154

Fimbriae type I and PME-CD of Moraxella bovis and Moraxella bovoculi as antigens for vaccines against infectious bovine keratoconjunctivitis

Sofia Acquistapace¹ Ana Umpiérrez¹ Pablo Zunino¹

¹Microbiología, Instituto de Investigaciones Biológicas Clemente Estable, Montevideo, Uruguay

Objectives: Infectious bovine keratoconjunctivitis (IBK) is an important ocular disease that affects cattle worldwide. It has become a serious economic and health problem. The main aetiological agents associated with IBK are Moraxella bovis and Moraxella bovoculi which have important genetic differences.

The aim of this study was to evaluate the presence and expression of type I fimbriae and outer membrane protein (OMP)-CD of M. bovis and M. bovoculi strains isolated from clinical cases of IBK in Uruguay, in order to identify conserved and highly immunogenic antigens as potential vaccine components.

Materials and Methods: A collection of clinical isolates of M. bovis and M. bovoculi, previously characterized in our laboratory was used to evaluate the presence and expression of I fimbriae and OMP-CD in strains recovered from IBK cases in Uruguay.

Fimbriae type I (fim09) and OMP-CD (omp-cd) genes were detected by partial PCR amplification with specific primers designed according to M. bovis sequences. All PCR products were confirmed after sequencing and BLAST analyses.

Twitching motility was evaluated by dropping grown cultures of Moraxella strains on brain heart infusion (BHI) agar plates at 37 °C. After 96 h of

incubation, growth halos were measured and twitching motility of each strain determined.

Expression and purification of OMP-CD was performed in vitro according to standard outer membrane protein procedures. Purified OMP-CD was identified by 2D gels (SDS-PAGE) and subsequent mass spectrometry analyses. Finally, immunogenicity of this protein was assessed by Western blot using sera and tears of healthy and IBK-affected animals.

Results: PCR amplification showed that fim09 gene was amplified in all *M. bovis* strains whereas it was not detected in any *M. bovoculi* strain. On the other hand, omp-cd was amplified within the whole collection of *M. bovis* and *M. bovoculi* strains. OMP-CD possess a 70% nucleotide similarity between species.

Twitching motility analysis, to evaluate fimbriae expression, was detected in strains from both species of *Moraxella*, and external halos with variable sizes were observed within the collection.

Regarding OMP-CD expression, 2D electrophoresis and mass spectrometry analyses evidenced that this protein was expressed in both *M. bovis* and *M. bovoculi* strains.

Finally, immunogenicity of OMP-CD was assessed by evaluating the presence of antibodies in natural infections of IBK with Western blot. It was seen that OMP-CD was highly immunogenic in tears and in sera from animals.

Conclusions: It was seen that fimbriae genes are distributed within *M. bovis* strains. The same primers did not amplify this fimbrial gene in *M. bovoculi* strains. This suggests that fimbrial genes significantly differ between both species. The incorporation of *M. bovis* and *M. bovoculi*, both together in vaccine formula, could generate better protection against IBK. On the other hand, OMP-CD was present in all *M. bovis* and *M. bovoculi* strains. This antigen was highly immunogenic as proved after analysis of specific antibodies. These results suggest that OMP-CD is a conserved antigen, that could be considered for new vaccine formulations.

P02-002-155

Control of an outbreak of bovine brucellosis in dairy herds. Vaccination Strategy

Luis Samartino^{1,2} Matias Arregui³

¹Pathobiology, INTA Veterinary Research Center, Hurlingham Buenos Aires, ²Veterinary, University of Salvador, Pilar, Buenos Aires, ³Pathobiology, National Institute of Agriculture Technology (Veterinary Research Center), Hurlingham Buenos Aires, Argentina

Objectives: Bovine brucellosis is actually present in all countries of Latin America. Control of this disease is based in serology, vaccination and elimination of positive animals. Although we know this strategy for many years, severe outbreaks of brucellosis still are present in the Continent. Mayor flows are lack of the enforcement of some control programs, and also a weak vaccination strategy. Two effective vaccines are available, S19 (smooth) and S RB51 (rough). Our objective is to show a successful strategy which can be able to control an outbreak of bovine brucellosis

Materials and Methods: Two dairy farms where brucellosis was present were selected for doing this study Farm A: 2224 animals with the initial prevalence of 1.75%, Farm B: 510 animals with an initial prevalence of 3.1%. Strain 19 was applied to all female calves between 3 and 8 months of age in both farms.

Serology: Buffer Plate Antigen Test (BPAT), Complement Fixation (CF) and Fluorescent Polarization (FPA) were the test used for diagnostic of brucellosis. A test and slaughter program was implemented. Due to poor results with the program, RB51 vaccine was applied in both farms to all S19 vaccinated animals. Positive animals by serology were eliminated as detected. Fetus and milk were analyzed by bacteriology methods. Strict management of the herd was implemented in order to avoid contact between infected and non-infected animals

Results: Animals were bleed and those positives were eliminated from the herd. Abortions were collected and burned as soon they were found. Serology indicates a strong infection. *Brucella abortus* biovar 1 was isolated. After a year of initiated the test and slaughter strategy results were very poor. Abortions were present and many positive animals were eliminated. *Brucella abortus* biovar 1 was isolated. For this reason, RB51 was applied in both farms to the whole herd, including pregnant animals. In consequence, serology went down to 0 and no record of abortions was observed

Both tables indicate that after RB51 vaccine implementation, brucellosis was controlled and eliminated from both herds. Two tables will show the evolution of the results

Conclusions: We studied two dairy farms, where animals, who were S19 vaccinated as calves, have a brucellosis outbreak and a test and slaughter program was applied. However after 6 months the results were very poor and RB51 vaccine was massive applied. Conclusion, S19 and RB51 are both good vaccines, however the importance is to know how and when those immunogens should be use. The advantages of RB51 are that it can be used anytime without complicate diagnostic and it doesn't induce abortion in pregnant animals previously vaccinated as a calf, but more important it is an excellent tool to control bovine brucellosis as was demonstrated in this study.

P02-002-156

EFFICACY OF A COMMERCIAL VACCINE WITH *Histophilus somni* AND LEUKOTOXOID OF *Mannheimia haemolytica* (HIPRABOVIS® SOMNI/Lkt) UNDER FIELD CONDITIONS

Eva Perozo^{1*} Ainhoa Puig¹ Beatriz Relancio¹ Ricard March¹

¹HIPRA, Amer, Province of Girona, Spain

Objectives: The aim of this study was to confirm the efficacy of a commercial vaccine containing *Histophilus somni* and Leukotoxoid of *Mannheimia haemolytica* (HIPRABOVIS® SOMNI/Lkt) in the reduction of respiratory clinical signs and in the number of concomitant treatments under real field conditions.

Materials and Methods: The study was performed in a farm with a census of 450 calves of different ages. Fifty-five animals between 4 and 6 weeks were included in the trial. These animals were randomly distributed in two groups taking into account their body weight on the day of vaccination. Animals from the negative control group received a placebo consisting of a buffered PBS solution (n=22). Animals from the vaccinated group received a commercial vaccine containing *Histophilus somni* and Leukotoxoid of *Mannheimia haemolytica* (HIPRABOVIS® SOMNI/Lkt) (n=33). Both groups received their treatments following the same route (subcutaneous), dosage (2ml/animal) and frequency (two doses, 21 days between first and second dose). Respiratory clinical signs and concomitant treatments were registered from all the animals

included in the trial to assess the efficacy of the vaccine. The significance level for of the statistical tests (Chi-square) was set at $\alpha=0.05$ (5%).

Results: Animals vaccinated with the commercial vaccine containing *Histophilus somni* and Leukotoxoid of *Mannheimia haemolytica* (HIPRABOVIS® SOMNI/Lkt) showed significantly less clinical respiratory signs and received less concomitant treatments than the negative control group.

Clinical respiratory signs (nasal secretion, ocular secretion, conjunctivitis, cough, respiratory rate and mucous nasal lesion) were observed in a higher percentage in animals from the control group (45.45%) than in animals vaccinated with the commercial vaccine containing *Histophilus somni* and Leukotoxoid of *Mannheimia haemolytica* (HIPRABOVIS® SOMNI/Lkt) (12.12%). Statistical differences between groups were observed (Chi-square test, p-value 0.005).

Concomitant treatments were registered in both groups during the whole study. In the control group 54.55% of animals were treated and in the vaccinated group 12.12%. Statistical differences were observed between groups (Chi-square test, p-value <0.001).

Conclusions: Vaccination with the commercial vaccine containing *Histophilus somni* and Leukotoxoid of *Mannheimia haemolytica* (HIPRABOVIS® SOMNI/Lkt) reduced the number of animals showing respiratory clinical signs and the number of concomitant treatments used during the first three months after the entrance in the fattening farm.

Characterization of immunological gene expression in the intestine of healthy calves.

Kayla Wade¹James Lowe²Elena Bichi²Brian Aldridge²

¹College Of Veterinary Medicine, ²Veterinary Clinical Medicine, University of Illinois, Urbana, IL, United States

Objectives: Gastrointestinal (GI) disease is a significant cause of morbidity and economic loss in young livestock. Understanding the pathophysiological significance of each element of the gut health 'triad' (immune system, microbiome, epithelium) will be useful in designing novel strategies to improve GI health in growing animals. In this study, we characterized mucosal inflammatory gene expression (IGE) profiles at different biogeographical sites of healthy calf intestines during the first 3 weeks of life.

Materials and Methods: Twelve calves from second parity cows on a single commercial dairy were removed from their dams immediately after birth and fed clean, high quality colostrum. The calves were fed milk replacer and health-monitored daily. A subset of calves (n=3) were euthanized at days 1, 3, 7, and 21, and mucosal tissue samples were taken from the duodenum, distal jejunum, ileum, and colon. Quantitative real time PCR analysis was performed to quantify the expression of interleukin 10, toll-like receptor (TLR) 2, 4, and 10, and tumor necrosis factor- α genes.

Results: The calves were clinically normal, and showed excellent feed intake and growth rates over the course of the experiment. There was a correspondingly low level of IGE in all calves, at all intestinal locations, and at all time points. The ileal mucosa exhibited a significantly higher pattern of IGE than all other sites, and TLR 4 had a three-fold higher expression than all other genes (p<0.05). The other sites sampled had low levels of both pro-inflammatory and anti-inflammatory cytokines relative to mean levels of gene expression from all samples.

Conclusions: As expected, the IGE profile of the intestine of this carefully managed and healthy calf group was subdued. The higher background of inflammatory activation in ileal mucosa could possibly be due to the relative abundance of Peyer's patches in this region. In future studies, we will compare the IGE profiles with the intestinal microbial communities and epithelial function of sick and healthy calves. Gaining an understanding of the connection between the immune system and microbial populations could lead to management solutions to GI health and reduce the use of antimicrobials.

Immunology/Vaccinology

P02-002-158

EFFICACY OF A COMMERCIAL VACCINE CONTAINING *Histophilus somni* AND LEUKOTOXOID OF *Mannheimia haemolytica* IN YOUNG CALVES UNDER FIELD CONDITIONS

Beatriz Relancio Beltran¹Antoni Foix¹Ricard March¹

¹HIPRA, Amer, Province of Girona, Spain

Objectives: Since 2011 an action plan on the rational usage of antimicrobials has been implemented by the EU Commission (Cars 2014). Antibiotics are the main measure for the control of pneumonic problems in cattle, while vaccination could be an alternative. The aim of this study was to demonstrate the efficacy under field conditions of a commercial vaccine with *Histophilus somni* and Leukotoxoid of *Mannheimia haemolytica* (HIPRABOVIS® SOMNI/Lkt) for the reduction of pneumonic problems caused by *Mannheimia haemolytica* and *Histophilus somni* in cattle and for the reduction of the number of drug treatments.

Materials and Methods: One-hundred-and-thirty calves between one and two months of age, clinically healthy, were randomly assigned to group A (n=64) and group B (n=66). Animals in group A were vaccinated subcutaneously with a commercial vaccine containing *Histophilus somni* and Leukotoxoid of *Mannheimia haemolytica* (HIPRABOVIS® SOMNI/Lkt) according to the recommended administration programme. Animals in group B (non-vaccinated) received PBS following the same schedule as group A.

Upon entering, the animals followed a standard protocol of hydration, deworming and bovine respiratory syndrome prevention (IBRV, RSV, BVDV and PIV-3 vaccine).

The main variables observed, recorded and compared to the control group were: clinical signs, lung damage and number of drug treatments. Different statistical test were performed. The level of significance used was 95%.

Results: Animals in group A (vaccinated calves) presented significantly lower clinical respiratory signs, lung damage and drugs treatments than the group B (non-vaccinated).

1. Clinical Respiratory Signs

Clinical respiratory signs scored from 0 to 3 (cough, dyspnea, nasal discharge, apathy, anorexia, lung auscultation, conjunctivitis and rectal temperature) were significantly higher in the group B (43.9%) than in the group A (20.3%) (Mann-Whitney test; p<0.01). Moreover, the true incidence for control and vaccinated groups was 4.72 and 1.40 episodes per 1000 animals at day of risk respectively (Mann-Whitney test; p<0.00001)

2. Lung Damage

The mean percentage of pneumonic tissue in the group A was lower than that for the group B (20.4% vs 41.3% respectively). When comparing the number of calves showing a percentage of pneumonic tissue equal or higher than 50%, the results were significantly higher in group B than in group A (6 vs 1) (T-test, $p < 0.05$).

3. Number of drug treatments

The number of treated animals, relapses, treatments and doses of drugs were significantly higher in the control calves than in the vaccinated ones (Chi-square and Mann-Whitney test, $p < 0.001$). 20.3% of the animals were treated in the vaccinated group, whereas 59.1% were treated in the non-vaccinated group. A total of 26 treatments as opposed to 144 were applied to vaccinated and control calves respectively. The number of doses of antibiotics administered to the non-vaccinated group was 5 times superior to the vaccinated one. Also, the number of doses of NSAID was 57 times superior in the non-vaccinated group.

Conclusions: The results of this study show that vaccination with the commercial vaccine with *Histophilus somni* and Leukotoxoid of *Mannheimia haemolytica* (HIPRABOVIS® SOMNI/Lkt) in field conditions achieves the reduction of pneumonic problems in calves based on the significantly decreased of clinical respiratory signs and pneumonic lung lesions, as well as the number of antibiotic treatments. Therefore, this vaccine would potentially help to follow the guidelines of the EU Commission by reducing the use of antimicrobials and improving the holdings health status.

Immunology/Vaccinology

P02-002-159

Passive Immunity And Natural Infection To Virosis Involved In Bovine Respiratory Disease

Bruno T. Silva¹ Camila C. Baccili¹ Sylvania M. F. Novo¹ Juliana F. D. Reis¹ Natália M. Sobreira² Edviges M. Pituco³ Viviani Gomes^{1,4,*}

¹Internal Medicine, University of São Paulo, São Paulo, ²Colorado Farm, Araras, ³Bovine Virus Laboratory, Biological Institute, ⁴University of São Paulo, São Paulo, Brazil

Objectives: The purpose of this research aims to evaluate the dynamics of specific neutralizing antibodies (Abs) for respiratory virosis and lymphocyte subpopulations in calves from birth to 240 days (d) of life.

Materials and Methods: Therefore, 19 calves negatives in serum neutralization (SN) and RT-PCR for BVDV were selected. Colostrum from cows vaccinated semiannually were selected by Brix index ($\geq 21\%$) and total protein ($9.6 \pm 1.6\%$), and stored at -20°C . Calves received a minimum amount of four liters of colostrum, divided into two feedings, in the first twelve hours after birth (a.b.). Among the 19 calves, five were randomly selected for monitoring the dynamics of neutralizing Abs and subpopulations of lymphocytes present in the blood front the natural challenges from 14 to 240d.

Results: Seroconversion was observed in 19 calves (100%) for all viruses after colostrum intake, displaying medians (Log_2) of 12.3, 9.0, 5.0 and 8.5 for BVDV, BoHV-1, BRSV and BPIV-3, respectively. BRSV (11.3-2.0) present oscillation of the Abs titer (Log_2) throughout the study: 3.0; 3.0; 4.0; 3.0; 0.0; 3.0; 0.0; 3.0; 3.0 to 14, 24, 74, 90, 120, 150, 180, 210 and 240 days of life. Median of the Abs titer (Log_2) demonstrated gradual decline for BVDV (12.8-3.3), BoHV-1 (10.0-3.3) and BPIV-3 (10.0-2.0). Despite this, the individual analysis of the Abs from the 5 calves showed an increase of the Abs titer for BRSV and

BoHV-1 between 90 to 120 d, and the BPIV-3 between 180 and 240 d. The half-life of Abs and time to seronegativity obtained were 36.2 ± 6.1 and 367.01 ± 68.7 d for BVDV; 50.7 ± 18.0 and 239.67 ± 66.88 d for BoHV-1; and 46.8 ± 21.1 and 303.36 ± 60.15 d for BPIV-3. B cells $\text{CD}21^+$ increased from 14 to 150d. Variations in T-cell proportions preceded the increase of the individual Abs titer. T helper lymphocytes showed slight increase between 44-74 days, and then, an abrupt reduction in its proportions between 90 to 150 days, and an increase in subsequent moments. $\text{CD}3^+\text{WC}1^+$ showed sharp reduction between 44-74 days followed by maximum peak between 74-90 days, with subsequent drop (120 d) and increase in subsequent moments. Only 2/5 calves demonstrated $\text{CD}3^+\text{CD}8^+$ response observing a peak between 120 to 150 d. Some calves showed decline of $\text{CD}25^+$ lymphocytes between 90-150 d. Bronchopneumonia diagnosis was confirmed by clinical examination in 4/5 calves between 90 and 120 days of age.

Conclusions: Passive immunity protected calves against natural infection after birth up to 74 days. Therefore, calves showed T cell response, specially $\text{CD}3^+\text{WC}1^+$, increase of specific antibody titers for BRSV and BoHV-1 and clinical findings to Bovine Respiratory Disease.

Immunology/Vaccinology

P02-002-160

Duration of positive PCR results for BVD, IBR, BRSV and PI3 following modified live viral systemic or intranasal vaccination in sero-negative calves

Victor Cortese^{1,*} Paul Walz² Dan Scruggs³

¹Technical Services, Zoetis, INC, Florham Park, ²Veterinary Medicine, Auburn University, Auburn, ³Technical Services, Zoetis, INC, Florham Park, United States

Objectives: to determine of duration of positive PCR and cycle time result for BVD, BoHV-1 BRSV and PI3 on blood, nasal swabs and transtracheal washes following vmodified live viral accinates administered systemically or intransally in sero-negative calves.

Materials and Methods: Twenty- 7 month old, BoHV1, BVDV, PI3 and BRSV sero-negative and BVDV virus negative calves were enrolled in the study. Animals were randomly assigned to group 1 vaccinated with a modified live viral vaccine containing BVDV types 1 and 2, BoHV1 BRSV, and PI3 (BoviShield Gold 5, Zoetis, INC) administered SQ or modified live BoHV1, BRSV and PI3 (Inforce 3, Zoetis, INC) administered intranasal. Calves had samples collected for PCR analysis (virus presence and cycle times) on day of vaccination, 72 hours post vaccination, and weekly until all calves were PCR negative for the various viruses. Samples consisted of deep nasopharyngeal swabs, whole blood (BVDV vaccinated group only) and transtracheal washes. A multiplex PCR for BoHV -1, BVDV (BVDV vaccinated calves only) types 1 and 2, Bovine Respiratory Syncytial Virus, and Parainfluenza virus-1 was run and cycle times were recorded. Calves required two successive weekly negative tests to be considered negative.

Study Design:

Calves were tested several times to ensure disappearance of colostrum antibodies against BoHV-1, BRSV, BVD and PI3. When the calves were sero-negative, samples were collected for BVDV persistent infection determination.

On the day of vaccination, all calves had serum and whole blood drawn, deep nasal swabs collected and transtracheal washes performed. SN titers were again performed and PCR for the presence of all five viruses

was run on these samples. Following collection of the samples, the calves were administered the appropriate vaccine: Bovishield Gold 5 or Inforce 3

Results: Intranasal vaccination: By day three after vaccination, calves vaccinated with Inforce 3 became positive on deep nasal swabs for both BoHV-1 virus (10/10) and BRSV virus (5/10), on day 3 transtracheal washes 3/10 calves were BRSV virus positive. Both samples were negative for PI3 virus. BoHV1Cycle times were variable with several calves positive under 30 CT (IBR-26-32), BRSV cycle times were higher on day 3 (30-38). All calves were BoHV-1 PCR negative on both nasal swabs and transtracheal washes by day 21. All calves were BRSV PCR negative on both samples by day 35 post vaccination. As in previous studies two calves were negative for one week and then became positive one week later then remained negative for the remainder of the trial. One calf was PCR positive for a single day (day 7) for PI3 virus. All buffy coat samples were negative on day 0 and were not tested again since BVDV was not included in the Inforce vaccinated group.

Systemic vaccination: A maximum of 4 calves were BVD virus positive by 14 days after vaccination on nasal swabs. A fewer number were detected using TTW or buffy coats. All positives were extremely weak with cycle times above 35 before any virus was detected (table 2). A total of four calves (2asal swabs and 2 TTW) were positive for BoHV-1 Again high cycle times were seen with the lowest time being 32 cycles. As anticipated both TTW and Nasal swabs were negative on all days following vaccination for both BRSV and PI3. All ten calves were virus negative by 21 days after vaccination.

Conclusions: This study provides valuable information on the duration of positive PCR for the viruses contained in two popular cattle vaccines. Many laboratories have tried to use cycle times as a method for differentiating wild virus exposure from PCR positives from vaccination. While this may be accurate when assessing PCR after systemic vaccination, the variability and low cycle times in the calves vaccinated intranasally make this method unacceptable. Durations of virus shedding may be longer if the calves are highly stressed but it is unlikely that many calves will be PCR positive to any virus in the vaccines by thirty days after vaccination.

Immunology/Vaccinology

P02-002-161

Comparison of interferon and BoHV1 IgA levels in nasal secretions of dairy cattle vaccinated with Inforce 3 prior to calving or on day of calving

Victor Cortese¹Amelia Woolums²David Hurley³John Bernard⁴Roy Berghaus⁵Tom Short⁶

¹Technical services, Zoetis, INC, Florham park, ²of Pathobiology and Population Medicine, Mississippi State University, Mississippi State, ³Food Animal Health and Management, Population Health, ⁴Animal and Dairy Science, ⁵Food Animal Health and Management, Population Health, University of Georgia, Athens, ⁶Outcomes Research, Zoetis, INC, Florham Park, United States

Objectives: To compare the level of antibodies against BHV-1 and levels and duration of interferon release in nasal secretions of cows vaccinated pre-calving or on the day of calving with a modified live viral, intranasal vaccine

Materials and Methods: Thirty two (2 parity of higher) Holstein cows were allocated to either receive intranasal vaccination (modified live

BoHV-1, BRSV and PI3, Inforce 3, Zoetis INC) two weeks prior to their projected calving date, or within 24 hours after calving. Nasal secretions were collected twice at a 12-hour interval on the day prior to vaccination (d = 0) and at 2, 4, 7, 10, and 14 days post vaccination to assay for IFN-alpha, IFN-beta, IFN-gamma and IgA directed against BHV-1; all were measured by ELISA.

Results: BHV1-specific IgA in nasal secretions: All cows seroconverted post vaccination. Significant increases in BHV-1 nasal IgA were seen in both groups. By day 4 after vaccination, cows vaccinated day of calving had significantly higher antibody levels than cows vaccinated pre-calving. These differences continued throughout the trial however by day 14 cows vaccinated pre calving were approaching similar levels of BHV1 IgA.

Interferon

Cows vaccinated on the day of calving showed minimal Alpha interferon responses. Cows vaccinated pre-calving showed two increases in Alpha interferon over baseline values. The first increase in levels was seen at 7 days after vaccination and a second increase began at 10 days after vaccination. By 14 days after vaccination the Alpha interferon levels were still climbing.

Both groups of cows showed an increase in beta interferon after vaccination. Fresh cows had a higher early release of Beta Interferon. Dry cows increased by day 4 after vaccination but by day 7 the levels seen post vaccination were at the same levels in both groups. Beta interferon levels again increased at ten days post vaccination in both groups.

The highest interferon levels were seen with gamma interferon. Cows vaccinated on day of calving showed an initial increase in Gamma interferon seen by day 4 with a second and higher level seen on day 10. The concentration of Gamma interferon in cows vaccinated on day of calving were beginning to decline by day 14 after vaccination. Cows vaccinated pre calving showed no increase in Gamma or total interferon until day 10.

Conclusions: All vaccines had increase in BHV-1 nasal IgA. In spite of prior viral vaccination during that lactation, cows still responded to an intranasal vaccination. The higher responses in both IgA and interferon post vaccination in cows vaccinated the day of calving in comparison with cows vaccinated pre-calving is in contrast to previous published studies demonstrating severe immune suppression following calving in dairy cows. However, these studies measured systemic immune suppression not local immune system responses. Either vaccination time may be appropriate in order to obtain both immune modulation due to interferon and specific immunity.

Comparison of Cytokine mRNA of Peripheral CD4+ CD8+ and gamma delta T cells between Healthy Holstein and Japanese Black Calves

Hiromichi Ohtsuka¹Kumi Kinouchi²Motoshi Tajima¹

¹Veterinary Medicine, Rakuno Gakuen University, Ebetsu, ²Kenchu Livestock Hygiene Service Center., Fukushima livestock hygiene service centre, Fukushima, Japan

Objectives: Weak calf syndrome presents as a newborn calf that is weak, sickly or slow to rise, and it appears mainly on Japanese Black (JB) in Japan. The function of T cells in JB calves may be inferior compared

with the other species. The objective of this study was to clarify the difference of leukocyte population and these cells function between healthy JB and Hol calves. Differences in the cytokines expression of CD4⁺, CD8⁺ and $\gamma\delta$ T cells will facilitate a better understanding of the differential function of T cell subsets in the immune response between two species calves.

Materials and Methods: Healthy 24 JB and 24 Hol calves were obtained at 1 week (N=8), 1 month (N=8) and 3 month (N=8) of age, respectively, and peripheral blood mononuclear cells (PBMCs) were aseptically separated. PBMCs were plated at 5x10⁶ cell/mL concentration in RPMI-1640 culture medium, containing 10% heat-inactivated fetal calf serum (FCS). We stimulated PBMCs for 12 hours at 37°C, in 5% CO₂ with 10 mg/mL phytohemagglutinin (PHA; Sigma Chemical Co, St. Louis, MO, USA). PBMCs were used for separation to CD4⁺, CD8⁺, and WC1-N1⁺ $\gamma\delta$ T cells by magnetic cell sorting (MACS) after the incubation. Enriched CD4⁺, CD8⁺, and WC1⁺ $\gamma\delta$ T cells were washed with PBS, and resuspended in TRIzol reagent. The target DNA sequence was amplified by specifically designed primers for β -actin, IFN- γ , IL-2, IL-4 and IL-10. Real-time reverse transcription polymerase chain reaction (RT-PCR) was performed with SYBR Green Master Mix.

Results: There were statistic different levels of mRNA expression in WC1-N1⁺ T cell between two groups. Levels of cytokines expressions in the JB Group were lower than those in the Hol Group in this study, and all analyzed cytokines were significantly different at month 1, and there were significant low levels of IL-2, IL-10 and IFN- γ expression at month 3. Although levels of cytokines expressions had little to no difference in the JB Group among the each analyzed points, expressions of cytokines at week 1 were lower than those expression at month 1 and 3 in the Hol Group

Conclusions: Our data substantiated the deficiency of cytokines expression activity in $\gamma\delta$ T cell on the JB calves. Since cytokines mRNA expression reaction of in $\gamma\delta$ T cells of JB calves was lower, reduced this cell function could aggravate infectious diseases and may explain some of the immunologic abnormalities accompanied.

Antigenicity differences between Japanese and European *Staphylococcus aureus* and *Escherichia coli* bovine mastitis isolates

Toni Prenafeta¹*Maximiliano Cesio¹

¹Laboratorios HIPRA, Amer (Girona), Spain

Objectives: The objective of this study was to analyse the reactivity of the antibodies induced by the STARTVAC[®] vaccine against *Staphylococcus aureus* and *Escherichia coli* bovine mastitis isolates from different areas of Japan and Europe.

Materials and Methods: In this study, the antigenicity of *S. aureus* Japanese isolates was evaluated by Western Blot using serum from a cow vaccinated with STARTVAC[®]. With this propose, cell wall-associated proteins from *S. aureus* were extracted, analysed in SDS-PAGE and immunodetected with the specific antiserum. In order to demonstrate that the antigenicity of the core lipopolysaccharide is constant in different isolates of *E. coli*, the reactivity of a specific monoclonal with several isolates of this bacterium was assessed. This was performed by exposing the monoclonal "E. coli J5 LPS PIERCE" to an indirect ELISA coated with different isolates of *E. coli*. In the same way, the ability of a serum from a

cow vaccinated with STARTVAC[®] to react against several *E. coli* isolates from different origins was studied also by an indirect ELISA.

Results: The *S. aureus* cell wall-associated proteins analysed by SDS-PAGE showed a pattern similar between the Japanese and European isolates. Moreover, this study demonstrated the antigenicity of the *S. aureus* isolates against the antibodies induced by the STARTVAC[®] vaccination. Concerning *E. coli*, all the Japanese and European isolates analysed by ELISA shared the same epitope in the lipid A of LPS recognised by a specific monoclonal antibody and, moreover, antibodies induced by STARTVAC[®] vaccination reacted against all the isolates.

Conclusions: In conclusion, this study indicates that *S. aureus* and *E. coli* bovine mastitis isolates from Japan and Europe, present common surface antigens recognized by antibodies induced with STARTVAC[®] vaccination.

Viability of bronchoalveolar CD14⁺ cells on calves infected with *Mannheimia haemolytica*

Camila F. Batista¹Renata C. Gomes¹Ricardo S. Jordão²*Heloisa G. Bertagnon¹Kamila R. Santos¹Fernando N. Souza¹Alice M. M. P. Della Libera¹ and Veterinary Clinical Immunological Research Group

¹Clinical Medicine, School of Veterinary Medicine and Animal Science of University of São Paulo, ²Laboratory of Immunobiological Production and Supplies of the Instituto Biológico, Instituto Biológico de São Paulo, São Paulo, Brazil

Objectives: *Mannheimia haemolytica* is a commensal bacteria that resides in the upper respiratory tract of bovines that plays a major role in Bovine Respiratory Disease Complex and it is major cause of the disease's evolution into a fibrinonecrotic pneumonia. This study used an experimental infection model to investigate the effect of *M. haemolytica* and the antimicrobial treatment on the viability of bronchoalveolar CD14⁺ cells.

Materials and Methods: The study inoculated *M. haemolytica* in 12 healthy Holstein calves, all of them at 6 months of age. CD14⁺ cell viability was evaluated in four distinct moments: M1: 2 days before intratracheal inoculation; M2: at the beginning of bronchopneumonia clinical signs; M3: 1 day after the end of antimicrobial treatment; M4: 1 week after the end of antimicrobial treatment. The calves were uniformly divided in 2 aleatory groups of 6 animals right after M2: Group 1 (G1): calves were treated with norfloxacin (5 mg/kg, SID for 7 days) and anti-inflammatory flunixin meglumine (2.2 mg/kg, SID for 3 days); Group 2 (G2): animals were treated only with norfloxacin.

Bronchoalveolar lavage (BAL) was performed by bronchoscopy using a flexible colonoscope (EC-250LP5, Fujinon[®], Saitama, Japan), attached to an image processor with a light source. The BAL was performed by squirting 80 mL of sterile saline through the colonoscope working channel and then collecting the fluid, which was centrifuged and the cellular pellet was resuspended in RPMI 1640 medium enriched with FBS 10%. BAL fluid samples tested for cell viability by employing the Annexin V-FITC (APOPTEST[™], Dako Cytomation, Finland, cat K2350) and propidium iodide. These procedures were conducted according to the flow cytometry techniques. The identification of CD14⁺ cells was based on their cytoplasmic granularities and mean fluorescence intensities following a two-step fluorescent immunolabeling protocol using primary anti-bovine monoclonal antibody (CD14) and secondary antibody coupled to long-wavelength fluorescent probes.

Results: The percentage of apoptotic and necrotic cells were analyzed in quadrants. The lower left quadrant represents viable cells, the upper left the apoptotic cells, the lower right the necrotic cells and the upper right cells that are both in late necrosis or secondary apoptosis.

The samples analyzed at the beginning of clinical signs of *M. haemolytica* infection (M2-between 15 and 18 h after inoculation) showed a lower percentage of apoptotic cells (2.13% in G1 and 1.12% in G2, $P=0.011$ and $P=0.004$, respectively) and a larger percentage of necrotic cells (70.35% in G1 and 78.55% in G2, $P<0.0001$ for both) when compared with M3 (3.29% in G1 and 5.93% in G2 of apoptotic cells, 28.55% in G1 and 27.00% in G2 of necrotic cells). This fact may be due to the large number of bacterial pathogens causing tissue damage, which in turn lead to necrotic cell death that amplify the inflammation signals. A different explanation for the increase of necrotic cells would be that *M. haemolytica* leukotoxin has the ability to induce apoptosis in bovine leukocytes, but in the presence of inflammatory cytokines, such as IL1 β and TNF α , these cells undergo necrosis. Other reason would be that infection or ischemia could induce necrosis, since they these processes involve cell death factors such as TNF α .

In order to combat the infection by the etiological agent, cells produce reactive oxygen species that help to eliminate the microorganism, but at the same time can cause tissue damage. Thus, not only cell apoptosis, but also phagocytosis of apoptotic corpuscles are important in the resolution of inflammation.

Conclusions: In conclusion, the experimental infection by *M. haemolytica* altered viability of CD14⁺ cells of BAL fluid. Additionally, it was possible to observe that the percentage of viable cells in the animals after antimicrobial therapy return to the normal values before experimental infection with *M. haemolytica*, and there was no observed benefit to combine the anti-inflammatory, since there was no difference in the apoptosis rates between G1 and G2 in BAL samples.

Efficacy and pharmacokinetics of intravenous famotidine in adult cattle

Christie Balcomb ¹Meera Heller²Heather Kynch³Munashe Chigerwe²Allison Meyer⁴

¹William R. Pritchard Veterinary Medical Teaching Hospital, ²Veterinary Medicine and Epidemiology, ³California Animal Health and Food Safety Laboratory, University of California, Davis, Davis, ⁴Animal Science, University of Missouri, Columbia, United States

Objectives: The objectives were to measure the pH of abomasal outflow fluid as an indicator of abomasal pH in adult cattle after administration of the H₂-receptor agonist famotidine as a single dose of 0.4 mg/kg IV or as three doses of 0.4 mg/kg IV every eight hours to mimic clinical application and secondly to describe the pharmacokinetic behavior of intravenous famotidine in adult cattle.

Materials and Methods: A prospective random two-way crossover study design was implemented using 4 healthy adult Angus steers previously fitted with duodenal cannulae located orad to the bile and pancreatic ducts. The steers were fed alfalfa hay ad-lib and whole corn and soybean hull meal pellets at 4 lbs/head 12 hours apart. On Day 1, steers were administered either 0.4 mg/kg famotidine or an equal volume of saline via jugular catheters. Whole blood and abomasal outflow samples were obtained at intervals for a 12-hour period. On Day 2, steers were administered either 0.4 mg/kg famotidine or saline IV at time 0, 8, and 16 hours. After a 24-hour washout period, the opposite treatments were administered and the study repeated. Whole blood and abomasal outflow samples were obtained at intervals for a 24-hour period. Abomasal outflow fluid was tested for pH using a commercial bench top pH meter within 5 minutes of sampling. Fluid pH was analysed using a mixed model in SAS 9.4 with treatment, sampling hour, and treatment*hour as fixed effects and steer and treatment period as random effects. Least square means were separated using least significant difference. Serum was separated and stored at -20° C until pharmacokinetic analysis. Serum famotidine analysis was performed using tandem liquid chromatography mass spectrometry and pharmacokinetic analysis was performed using commercial software.

Results: The treatment*sampling hour interaction affected abomasal outflow pH for both a single dose and multiple doses of famotidine (P < 0.001). A single dose of intravenous famotidine resulted in a significant increase of abomasal outflow pH as compared to the control group for 4 hours after administration (P < 0.05). When administered every 8 hours, the abomasal outflow pH of the famotidine treated group was greater than the control group for 4 hours after the first dose (P = 0.03), 2 hours after the second dose (P < 0.0001), and 1 hour after the third dose (P < 0.0001). Pharmacokinetic analysis demonstrated that famotidine had a terminal half-life of 3.33 (3.21 – 3.54; median and range) hours, a volume of distribution of 0.042 (0.014 – 1.89) L/kg and a clearance of 1.26 (0.625 – 11.5) mL/min/kg.

Conclusions: A single intravenous dose of famotidine administered at 0.4 mg/kg increases abomasal outflow pH of adult cattle for up to 4 hours compared with saline control. Administration every 8 hours to mimic a clinical therapeutic regime resulted in significantly higher abomasal outflow pH for 4 hours after the first dose; however, the effect seemed to decrease after each subsequent dose. Results of this study indicate that famotidine raises the abomasal pH and may be an effective treatment for abomasal ulceration in cattle. The efficacy of treatment may decrease over time or may require more frequent dosing to sustain elevated abomasal pH.

The effect of milk replacer and different components of milk replacer in an intestinal loop model for haemorrhagic enteritis in calves.

Bonnie Valgaeren ¹Evy Goossens²Stefanie Verherstraeten²Stijn Schauvlieghe³Freddy Haesebrouck²Filip Van Immerseel²Richard Ducatelle²Piet Deprez¹Bart Pardon^{1*}

¹Internal Medicine and Clinical Biology of Large Animals, ²Pathology, Bacteriology and Avian Diseases, ³Surgery and Anesthesia of Domestic Animals, Ghent University, Merelbeke, Belgium

Objectives: Recently, an intestinal loop model was developed to induce and study Clostridium perfringens induced necrohaemorrhagic enteritis in calves. In this model co-inoculation of C. perfringens with commercial milk replacer (MR) had a strong predisposing effect on the development of necrosis in this model. MR is composed by a number of dairy-derived ingredients, and for economic reasons also vegetal-derived ingredients. The objective of the present study was to identify the predisposing component of MR.

Materials and Methods: An intestinal loop model was conducted as previously described, by injecting intestinal loops with C. perfringens culture. In the first experiment, different concentrations of MR (0%, 0.25%, 2.5%, 10% and 25%) were made by dissolving commercial MR in sterile isotonic saline. Every concentration was tested in 6 loops, in 2 calves. In each loop 20 mL of MR solution in combination with 20 mL of C. perfringens culture grown overnight was injected. In the second experiment, the predisposing effect of two commercial MR's (MR1 and MR2) either with and without skimmed milk powder were compared, with saline as a negative control. The experiment was repeated in 3 calves, with 5 loops of each condition in each calf. Each loop was injected with 20 mL of bacterial culture and 20 ml of a 25% MR solution. In the last experiment, the predisposing effect of different components of commercial MR was tested. Loops were randomly divided over 3 calves, and 3 loops per ingredient were injected with bacterial culture in combination with a 25% solution of each of the following ingredients of MR: skimmed milk powder, casein, lactose, calcium carbonate, soy protein concentrate, potato protein concentrate, whey powder, whey permeate and whey protein concentrate.

Results: In the first experiment, necrosis could be induced in 40±0.23% of the loops injected with a 25% MR solution in combination with C. perfringens culture. In none of the loops injected with lower concentrations of MR necrosis was observed. There was no significant difference between the two tested MR's. However, significantly more loops inoculated with culture and milk replacer showed necrosis compared to loops inoculated with culture and saline. Loops inoculated with sterile medium and MR showed negligible number of loops with necrosis (0±0% for MR1, 0.03±0.05% for MR2). Loops inoculated with culture and both MR's showed similar proportion of loops with necrosis (respectively 0.67±0.19% for MR1, 0.65±0.28% for MR2), and only 0.27±0.19% of the loops inoculated with culture and saline showed necrosis.

In the final experiment, the most loops with necrosis could be induced by injecting culture in combination with MR (67±52%) and skimmed milk powder (60±23%), followed by whey permeate, casein, whey protein concentrate, whey powder and lactose (40±52%, 20±45%, 20±42%, 10±32% and 10±32% respectively). None of the loops injected with one of the other components showed necrosis on histological examination. There were significantly more loops with necrosis in the loops inoculated with culture and MR and culture with skimmed milk powder compared to all other components, except whey permeate.

Conclusions: The predisposing effect of MR on haemorrhagic enteritis in calves is concentration-dependent. In high concentration, different commercial MR's and skimmed milk powder have similar predisposing effects. This effect was significantly higher than the effect of vegetal-derived ingredients of MR. Therefore, it can be concluded that the predisposing effect of MR is due to the dairy ingredients. Further experiments are needed to identify the specific (combination of) component(s) of milk powder responsible for the observed predisposing effect on haemorrhagic enteritis in calves.

Influence of enzootic bovine leukosis on immune response of naturally infected cattle

Milton Ricardo Azedo¹·Maiara G. Blagitz²·Camila F. Batista²·Fernando N. de Souza²·Fernando J. Benesi²·Alice M. M. P. Della Libera²

¹School of Veterinary Medicine, Metropolitan University of Santos, Santos, ²Department of Medical Clinics, School of Veterinary Medicine and Animal Science, São Paulo, Brazil

Objectives: Enzootic Bovine Leukosis (EBL) is an infectious, chronic, neoplastic disease, which undermines the lymphopoietic organs and is associated with the development of persistent lymphocytosis (PL) and lymphosarcoma. Infected animals present a decrease of production, by its direct and indirect harmful effects. However, its effect on the function and quantity of lymphocyte subpopulations, and its role in the establishment of other opportunistic diseases, are unclear. We evaluated the immune response of Holstein cows infected with Bovine Leukosis Virus (BLV), after antigen challenge provided by vaccination against foot and mouth disease (FMD) virus.

Materials and Methods: Blood samples from ten seropositive cows without PL, from ten seropositive cows expressing PL, and from ten seronegative cows were collected before challenge and after challenge, weekly, for seven weeks. We evaluated the quantitative changes of different subpopulations of leukocytes; the function of B lymphocytes, through the quantification of different isotypes of immunoglobulins (Ig) serum concentration; the rate of lymphocyte proliferation; the rate of cell death by apoptosis or necrosis; and the serum concentrations of interleukin-10 (IL-10), IL-12, interferon- γ (IFN- γ), and tumor necrosis factor- α (TNF- α). The normality of distribution of the results was verified using the Anderson-Darling test, and their homoscedasticity, using the F test (for data with normal distribution) or the Levene test (for data without normal distribution). For the evaluation of differences between the average results, according respectively to the presence or absence of homoscedasticity, we used, for data with normal distribution, One-way ANOVA test, followed by the Tukey-Kramer test or the t test, and, for data without normal distribution, the Mann-Whitney test or the Kruskal-Wallis test. Results with $p \leq 0.05$ were considered statistically significant.

Results: No differences in IgG1, IgM, and IgA concentrations were found among sampling time and, every time, among groups. IgG2 increased after challenge (T0) in all cows ($p < 0.05$). Cows with PL, each time, since 17 days after T0, IgG2 had lower ($p < 0.01$) than cows of other groups, indicating that cows with PL present less intense and less enduring humoral response. An increased rate of lymphocyte proliferation ($p < 0.01$) 24 days after T0 was found in all cows. Since then, there was an increase in the percentage of $\gamma\delta$ -lymphocytes ($p < 0.05$) and a later decrease in serum IgG2 ($p < 0.05$). Cows with PL had higher $\gamma\delta$ -lymphocytes percentage ($p < 0.05$), possibly leading to the more intense and earlier

decrease in IgG2. PL was due to a lower rate of apoptosis, since the percentage of leukocytes undergoing apoptosis was lower ($p \leq 0.001$) in cows with PL than in other groups. Th1 cytokines (IL-12 and IFN- γ) were higher in non-PL infected cows ($p < 0.01$), whereas Th2 cytokines (IL-10 and TNF- α) were higher in infected cows with PL ($p < 0.01$). IL-10 ($p < 0.01$), TNF- α ($p = 0.005$), and IFN- γ ($p < 0.01$) increased three days after T0, and IL-12 increased ($p < 0.001$) ten days after T0. The increase in IL-10 lasts until 31 days after T0 and may account for the higher rate of $\gamma\delta$ -lymphocyte proliferation found after 31 days since T0. The majority of circulating B lymphocytes in cattle was B1 lymphocytes and, in BLV-infected cows, PL occurred due to an increase in the percentage of B1a lymphocytes ($p < 0.05$).

Conclusions: Results allow us to conclude that lymphocytotic BLV-infected animals have impaired immune response after an antigenic challenge, represented by the vaccination against FMD virus. IgG2 serum concentration after the challenge indicate that cows with PL present less intense and less enduring humoral response, probably led by their higher increase in the percentage of circulating $\gamma\delta$ -lymphocytes. Moreover, PL is due to a lower rate of apoptosis, rather than to a higher rate of lymphocyte proliferation, and occurs due to an increase in the percentage of circulating B1a lymphocytes.

Internal Medicine

P03-003-105

An abattoir study of ruminoreticular adhesions and retention rate of rumen magnets in cattle at slaughter

Roger Blowey¹·Alice Elliott¹

¹Gloucester Vet, Gloucester, United Kingdom

Objectives: Although there are numerous reports of traumatic reticuloperitonitis (TRP, 'wire') in cattle, we are unaware of any UK studies of the prevalence of the condition, although a Danish abattoir study of 1491 dairy cows found that 16% had foreign bodies in their reticulum and of these 10% were associated with lesions. As rumen magnets cost only £2 per animal, if they are effective, routine dosing must be an extremely sensible precaution. The current study assessed the abattoir prevalence of TRP, and the retention rate of rumen magnets.

Materials and Methods: An initial postal survey of 56 dairy farms in the Gloucester area identified the number of dairy farms administered magnets to all cows as a routine. These farms were then invited to send cows to a local abattoir on 3 specific days, and they were examined at slaughter with other cattle submitted. At slaughter, the rumen, reticulum, omasum, abomasum, spleen and liver of 373 cows, 137 dairy and 236 beef, were visually assessed and palpated by an assessor, and organs with adhesions and/or abscesses were recorded and classified (acute/fibrinous, chronic/fibrous, or a mixture). A second assessor searched the rumen and reticulum for magnets. The age and breed was taken from abattoir and passport records.

Results: Only 30% of farms administered magnets to all cows. Of the 373 cows examined at the abattoir 91 (24.4%) showed lesions of peritonitis, 47 (34.3%) dairy and 44 (18.6%) beef cows. Many of the lesions were very mild, although frank abscesses were visible in 23 (6.2%) of the cows overall, 14 (10.2%) of the dairy animals and 9 (3.8%) beef. The significant association between breed of cow (dairy versus beef) and presence of reticuloperitonitis lesions ($P < 0.001$) confirms that dairy cows in are at increased risk of TRP. Magnets were detected in the rumen or reticulum of 29 (21%) of dairy cows and none in beef cows. When comparing the lesions in dairy cows with and without magnets, there was

no difference in the level of peritonitis, but there were no abscesses in cows with magnets but 14 (13%) of the 108 dairy cows without magnets had abscesses. Thirty-nine cows from four farms were examined where the farm stated that all cows had received a magnet prior to slaughter. Of these, only 24 (61.5%) contained a magnet at the abattoir.

Conclusions: Although dairy cows were worst affected, both dairy and beef animals had lesions suggestive of TRP. There was a significant association between magnet absence and presence of non-reticular peritoneal adhesions ($P < 0.05$) and all adhesions in the cows with magnets were reticular only and no abscesses were present. This suggests that magnets can inhibit foreign body migration from the reticulum, supports their use both therapeutically and prophylactically, and suggests that more widespread use would improve both the welfare and productivity of dairy and beef cattle.

P03-003-106

Physicochemical Approach To Acid-Base Disorders In Hospitalized Cattle

Olimpo Oliver¹, Adriana Garzon¹, Rubiela Castañeda²

¹Animal Health, Faculty of Veterinary Medicine and Zootechny, National University of Colombia, ²Microbiology, Faculty of Sciences, Pontificia Universidad Javeriana, Bogota DC, Colombia

Objectives: The objectives of this retrospective study were to determine the main acid-base disorders observed in hospitalized cattle using the physicochemical and the traditional Henderson-Hasselbalch (H-H) approaches and also to compare their diagnostic usefulness.

Materials and Methods: An eight-year retrospective study was conducted at the Large Animal Hospital, Faculty of Veterinary Medicine and Zootechny of the National University of Colombia that involved all the medical records of bovine patients admitted during that period. The inclusion criteria in the study were that the patient had to have complete results of arterial or venous blood gases, serum electrolytes (Na^+ , K^+ , Cl^-), and total plasma protein (TPP) from samples taken before any treatment was administered at the hospital. On each history, signalment, main complaint, working diagnosis, biochemical profile and hemogram were also collected. In all the cattle that met the inclusion criteria, venous or arterial blood was collected into a Na-heparin blood gas syringe and analyzed for pH, pCO_2 , calculated HCO_3^- and Base Excess (BE) using a blood gas analyzer, serum concentrations of Na^+ , K^+ , Cl^- were measured in venous blood using an ion-selective electrode analyzer and TPP were measured using a refractometer. Anion Gap (AG) was calculated as: $(\text{Na} + \text{K}) - (\text{Cl} + \text{HCO}_3^-)$; Strong ion difference (SID) and Strong ion gap (SIG) were calculated as: $\text{SID}_3 = (\text{Na} + \text{K}) - (\text{Cl})$, $\text{SIG} = \text{A}^- - \text{AG}$. A^- is net negative charge of plasma proteins; $\text{A}^- = 0.22x [\text{total protein, g/L}] / (1 + 10^{(\text{pKa} - \text{pH})})$.

Results: Only thirty-one patients of the 245 hospitalized bovine met the inclusion criteria in the 8-year period. Out of the 31 patients, 16 had arterial (A) blood gases measured and in 15 they were measured in venous (V) blood. The values observed were: $\text{A} \text{pH} = 7.37 \pm 0.15$; $\text{V} \text{pH} = 7.39 \pm 0.15$; $\text{A} \text{pCO}_2 = 39.82 \pm 15.19 \text{ mmHg}$; $\text{V} \text{pCO}_2 = 39.81 \pm 9.32 \text{ mmHg}$; $\text{A} \text{HCO}_3^- = 23.02 \pm 7.95 \text{ mmol/L}$; $\text{V} \text{HCO}_3^- = 26.2 \pm 10.55 \text{ mmol/L}$; $\text{A} \text{BE} = -2.25 \pm 9.61 \text{ mmol/L}$; $\text{V} \text{BE} = 1.33 \pm 12.69 \text{ mmol/L}$; $\text{Na} = 135.35 \pm 12.72 \text{ mmol/L}$; $\text{K} = 4.04.1 \pm 1.01 \text{ mmol/L}$; $\text{Cl} = 96.71 \pm 15.47 \text{ mmol/L}$; $\text{SID} = 37.49 \pm 10. \text{ mmol/L}$; and $\text{A}^- = 12.83 \pm 2. \text{ mmol/L}$; $\text{AG} = 18.01.7 \pm 8.88 \text{ mmol/L}$; $\text{SIG} = -5.17 \pm 8.24 \text{ mmol/L}$. Using the H-H approach acid base abnormalities were found in 83.3% of the patients compared to 93.5% using the physico-chemical approach. 61.3% had SID acidosis, 38.7%

had hyperproteinemic acidosis, 16.12% had SID alkalosis and 38.7% had hypoproteinemic alkalosis.

Conclusions: The physicochemical approach allowed detecting more acid base disturbances in hospitalized bovines than the H-H approach. These results indicate the need to determine accurately the acid base disorders in hospitalized cattle for their adequate treatment.

Internal Medicine

Practic application of thoracoscopic lung biopsy in bovine respiratory disease

Natividad Perez-Villalobos¹, Iñaki Espinosa², Gorka Aduriz³, Jose Carlos Ibabe³, Nekane Cortabarria³, Jorge Gonzalez⁴, Juan Vicente Gonzalez-Martin¹, Antonio Gonzalez-Bulnes⁵, Susana Astiz^{5,6,*}

¹TRIALVET SL, ²Clinico libre, Madrid, ³Neiker Tecnalia, Vizcaya, ⁴MICROS VETERINARIA, León, ⁵Animal Reproduction, INIA, Madrid, Spain

Objectives: The thoracoscopy is an easy and safe diagnostic technique, already used in healthy bovines. This technique allows sample collection directly from diseased intrathoracic organs (biopsy). If the thoracoscopy can be safely used to take lung biopsies from BRD-diseased animals, the specific etiological cause of the particular lesions could be approached. This would be of huge interest for the bovine medicine and the bovine productive sector.

Hence, the aim of the study was to evaluate the quality of lung samples obtained through thoracoscopic biopsy and the influence of specific factors (sex, weight, and lung lobe) on the quality of such samples.

Materials and Methods: Lungs from 40 bovines (experiment 1) obtained at slaughterhouse were postmortem biopsied with the thoracoscopic equipment based on flexible endoscopes and lung samples quality and potential factors influence analyzed. In experiment 2 diagnostic information from in vivo samples (including thoracoscopic biopsies) coming from three BRD-diseased animals were compared with ultrasonography, classical exploration, and laboratory analyses of bronchial alveolar lavage, nasopharyngeal swab and blood analyses.

Results: A total of 91.25% (73/80) of valid samples was obtained. Samples taken from cranial lobes included significantly more often lung tissue (11.6%; $P = 0.0038$) than caudal lobes. Samples taken from lighter ($< 250 \text{ Kg}$) animals tended to have more often valid samples, with more parenchyma (1803.7 ± 1069.8 vs. 1255.3 ± 886.7 microns/1000; $P = 0.038$) than heavy animals ($\geq 250 \text{ Kg}$). These differences could be caused by the different pleural characteristics observed in cranial vs. caudal lung lobes (166.2 ± 45.5 vs. 194.1 ± 77.5 microns of pleural width; $P = 0.112$), in lighter vs. heavier animals (162.6 ± 60.5 vs. 186.6 ± 64.4 microns of pleural width; $P = 0.212$), in female vs. male (556.4 ± 445.6 vs. 652.2 ± 534.5 microns/1000 pleural surface, $P = 0.14$) and in $< 14 \text{ mo}$ vs. $\geq 14 \text{ mo}$ old (488.0 ± 387.1 vs. 688.5 ± 538.1 microns/1000 pleural surface; $P = 0.113$). The macroscopic estimation of the pulmonary tissue based on the observation of pinkish speckled appearance performed by the endoscopist resulted to foresee the existence of pulmonary tissue ($\text{Se} = 97.2\%$; $\text{Es} = 71.4\%$; $\text{k value} = 0.687$ and $P < 0.0001$), which has a great practical value as it allows deciding intraoperatively the repetition of the biopsy.

A total of 95.23% (20/21) of valid samples was obtained and a better diagnostic capacity was demonstrated for the thoracoscopy and thoracoscopic biopsy, when compared to ultrasonography, classical exploration, bronchial alveolar lavage, nasopharyngeal swab and blood analyses.

Conclusions: Complete and descriptive information about characteristics of the lesions and the causal agents were available, even in the case of *Mycoplasma bovis*, with a notably better diagnostic efficacy than with other analytical techniques applied. Based on these results, thoracocopy and thoracoscopic lung biopsy are demonstrated as safe, easy, useful and better diagnostic tools for BRD-diseased animals.

Inducing abomasal lesions with phenylbutazone: a case report

Aline Morgado¹, Priscilla Nascimento¹, Stefano Hagen¹, Maria Claudia Sucupira¹

¹Universidade de São Paulo, São Paulo, Brazil

Objectives: Abomasal ulcers cause economic losses but little information about diagnosis and treatment is available, especially for adult ruminants. Omeprazole and ranitidine are the mucosal protectors commonly used in veterinary medicine, but there are no specific recommendations for polygastric animals. We studied sheep to evaluate the preventive action of ranitidine and omeprazole and identify markers for abomasal lesions caused by phenylbutazone administration.

Materials and Methods: Phenylbutazone was defined as the most ulcerogenic non-steroidal anti-inflammatory drug for goats treated twice a day for 12 days. Respecting the half-life of phenylbutazone in ovines of approximately 18 hours, daily intravenous administration of 4mg/kg of body weight were made in four healthy adult sheep fitted with abomasal cannulas. Endoscopic images obtained directly from the abomasum, blood samples and the physical parameters were collected daily from the first day of phenylbutazone administration up to a maximum of 14 days of this induction.

Results: On the 2nd day of phenylbutazone administration one sheep showed apathy, ruminal atony and anorexia; the serum fibrinogen was 6g/L, the abomasal pH was 2.52 and the acid secretion, 2.4 mL NaOH 0,1N. On the 3rd day, rounded lesions on the body portion of the abomasum appeared; the cardiac frequency was 128 beats per minute, the respiratory frequency was 44 breathes per minute and the animal showed two complete and one incomplete ruminal contraction during three minutes observation. The fibrinogen concentration remained 6g/L, the serum pepsinogen was 4.5UI, the abomasal pH was 2.88 and the acid secretion, 7.08 mL NaOH 0,1N. On the 4th day, this animal showed cardiac and respiratory frequencies a little higher than the normal, but the other parameters were adequate. The image of the abomasum showed a great improvement in the appearance of the mucosa. On the 5th day the endoscopic examination showed up again with rounded lesions in the body region and in the afternoon the animal presented severe discomfort, mainly noticed by tachypnea and the unusual position in which the animal was lying. Because of these signs on the next day the sheep did not receive the anti-inflammatory drug. The endoscopic images revealed significant diffuse lesions in the abomasum, in a quantity impossible to quantify. Ruminal movements were greatly decreased and weak and the animal was quiet. The abomasal pH was 3.05 and the acid secretion, 6.28 mL NaOH 0,1N. From the 2nd day without phenylbutazone administration the abomasum was apparently clean of lesions and ruminal movements were restored.

Conclusions: In the observed case only removing the stimulus of the injury was enough for the spontaneous recovery of abomasal mucosa in one day. The other animals used didn't show macroscopic abomasal

damage until the 9th day so the administration of phenylbutazone started to be done twice a day from the 10th day. No macroscopic damage in the abomasum, appetite decrease or clinical parameters alterations was observed until the 14th day of phenylbutazone administration. The difficulty to induce abomasal ulcer shows that healthy and well-fed ovine tolerate phenylbutazone in the dose and during the time used better than expected.

BOVINE TRYPANOSOMOSIS: HAEMATOLOGY, SERUM GLUTAMIC OXALO-ACETIC TRANSAMINASE (SGOT) AND CREATININE (CRT) LEVELS IN THREE BREEDS OF NIGERIAN CATTLE

Olaekan Taiwo Lasisi¹, Olamilekan G. Banwo¹, Folajimi B. Abodunde¹

¹University of Ibadan Nigeria, Ibadan, Nigeria

Objectives: Trypanosomosis is endemic and it constitutes a hindrance to livestock productivity in Africa. Although anaemia is a prominent feature of natural bovine trypanosomosis, its effects on serum glutamic oxalo-acetic transaminase (SGOT) and creatinine (CRT) levels in Nigerian cattle have not been researched. This study was therefore carried out to determine the effects of natural bovine trypanosomosis on the haematology, serum glutamic oxalo-acetic transaminase (SGOT) and creatinine levels in some breeds of Nigerian cattle.

Materials and Methods: A total of 243 cattle comprising 88 apparently healthy and 155 trypanosome-infected cattle (without other blood and helminth parasites) of both sexes among Sokoto Gudali, Red Bororo and White Fulani breeds, were used for the study. The animals were sampled from three different farms from Ibadan over a period of nine months. Dentition technique was used to estimate ages of the cattle sampled. Modified McMaster technique was used to ascertain levels of helminthosis. Buffy coat and Giemsa staining techniques were used to make diagnosis and determine morphology of the trypanosomes. The Packed Cell Volume (PCV), Haemoglobin Concentration (Hb) and Red Blood Cell Counts (RBC) were determined using poch-100iV Diff (Sysmex Animal health), while the serum SGOT levels were determined using Randox[®] kits (Randox Laboratories, UK) and CRT levels were determined using Serum creatinine kit (Fortress Diagnostics, Ltd UK). All data obtained was subjected to descriptive statistics and SPSS statistical package version 9.0 at a significance level of 5%.

Results: Mixed infections with *Trypanosoma congolense* and *Trypanosoma brucei* were recorded. Across all the breeds of cattle, there was anaemia with significantly ($P < 0.05$) decreased values of PCV, Hb and RBC. A significant ($P < 0.05$) increase in the value of serum enzyme concentration of SGOT and CRT was obtained in the naturally infected cattle across the breeds. Cattle above two years of age were found susceptible to natural trypanosomosis across the three breeds. There was no sex disposition in both the haematological profile and serum SGOT and CRT values

Conclusions: The deleterious effects of trypanosomes on the haematology of cattle is reaffirmed while it is suggested that leakage of enzymes from their intracellular stores due to trypanosome-induced cell membrane disruption, increased production in the liver and/or decreased excretion through the glomerular filters might have resulted from hepatotoxicity and nephrotoxicity due to parasite derived toxic factors. Cattle farmers in Nigeria have been advised appropriately.

Injection Site Protocols: Bacterial Loads on Skin of Unclipped Gluteal Sites Following Treatment with 70% Isopropyl Alcohol-Soaked Swabs in Dairy Cows

Peter Cockcroft ¹Helen Redfern ²

¹School of Animal and Veterinary Sciences, University of Adelaide, Adelaide, Australia, ²Glenthorpe Veterinary Centre, Uttoxeter, United Kingdom

Objectives: Intra-muscular injection in cattle is a common procedure in cattle practice. There is a wide variety of bacterial flora present on cattle skin which may lead to abscess formation and carcass damage following contamination of the needle at the time of injection. There is no evidenced-based protocol for the treatment of skin before an intra-muscular or sub-cutaneous injection is administered in cattle. The aim of this study was to compare the bacterial load of unclipped gluteal skin in dairy cows following either no treatment or treatment with a standard 70% isopropyl alcohol-based skin treatment protocol.

Materials and Methods: Twenty Holstein-Friesian dairy cows from a commercial dairy herd in Cambridgeshire, England, were used in this randomised, blinded, controlled study. On each of the experimental cows an area of unclipped gluteal skin on one side of the pelvis was treated with swabs soaked in 70% isopropyl alcohol-based using a standard protocol. A contra-lateral area of skin was left untreated as a control. All the experimental skin sites were sampled using a swab followed by bacterial culture and quantitative analysis of bacterial load.

Results: There was a statistically significant decrease in the bacterial colony forming units per mL for the isopropyl-alcohol treatment group when compared to the control group ($p \leq 0.01$, Mann-Whitney U-test). There was a 58% reduction in the median bacterial load of the treated sites when compared to the bacterial load of the untreated sites. There was no statistically significant difference between either the right and left treatment sites ($p > 0.05$, Mann-Whitney U-test) or the right and left control sites ($p > 0.05$, Mann-Whitney U-test).

Conclusions: This study has demonstrated that a treatment protocol with swabs soaked in 70% isopropyl alcohol can substantially reduce the skin bacterial load but not eliminate all bacteria. This study supports the use of skin swabbing prior to injection in-order to reduce the risk of needle contamination.

Agreement among sampling methods used to identify viral and bacterial pathogens in dairy calves with naturally-occurring respiratory disease

Amelia Woolums ¹Danielle Doyle ¹Brent Credille ²Roy Berghaus ²Terry Lehenbauer ³Sharif Aly ³John Champagne ⁴Pat Blanchard ⁵Beate Crossley ⁵Londa Berghaus ⁶Sarah Cochran ²

¹Department of Pathobiology and Population Medicine, Mississippi State University, Mississippi State, ²Department of Population Health, University of Georgia, Athens, ³Department of Population Health and Reproduction, and Veterinary Medicine Teaching and Research Center, University of California, Davis, Davis, ⁴Veterinary Medicine Teaching and Research Center, University of California, Davis, Tulare, ⁵California

Animal Health and Food Safety Laboratory System, University of California, Davis, Davis, ⁶Department of Large Animal Medicine, University of Georgia, Athens, United States

Objectives: Bovine respiratory disease (BRD) is common in dairy calves, and antemortem sampling to identify respiratory pathogens is often undertaken. Sampling methods used include the nasal swab (NS), deep guarded nasopharyngeal swab (NPS), transtracheal wash (TTW), and bronchoalveolar lavage (BAL). However, the agreement among these tests has not been well characterized. The objective of this study was to compare the agreement of results obtained by NS, NPS, or BAL with those obtained by TTW for identification of bacterial and viral respiratory pathogens in pre-weaned dairy calves with naturally occurring BRD.

Materials and Methods: Calves at a single calf rearing facility with naturally occurring respiratory disease in the first 90 days of life were enrolled if they had a score of 5 or greater on the University of Wisconsin Calf Respiratory Scoring Chart, a fever of 103°F (39.4° C) or higher, and at least 2 cm of pulmonary consolidation identified by transthoracic ultrasound. Calves that had ever been treated for respiratory disease, or that had received intranasal modified live viral respiratory vaccine in the previous 30 days, were excluded. A NS, NPS, TTW, and BAL were collected sequentially from each calf using standard methods. Bacterial pathogens were identified by aerobic bacterial and mycoplasma culture, and viral pathogens were identified by real time RT-PCR. Mycoplasma sp. isolated were subjected to PCR to specifically identify *M. bovis*. Agreement between the results of TTW and the NS, NPS, or BAL was determined by calculation of the kappa statistic. Values of kappa were categorized according to these levels of agreement: < 0.21 = poor; $0.21 - 0.40$ = fair; $0.41 - 0.6$ = moderate; $0.61 - 0.80$ = good, and $0.81 - 1.00$ = very good.

Results: One hundred calves were enrolled. No samples were positive for bovine herpesvirus-1 (BHV-1), bovine viral diarrhoea virus (BVDV), or *Histophilus somni*. Nearly all samples were positive for *Mycoplasma* sp., leading to low values for kappa for *Mycoplasma* sp. Relative to the TTW, all sampling methods showed very good agreement for identification of *Pasteurella multocida*, *Mannheimia haemolytica*, or *Mycoplasma bovis*. In contrast, for identification of bovine respiratory syncytial virus (BRSV) and relative to TTW, agreement was moderate for NS, good for NPS, and very good for BAL. For identification of bovine coronavirus (BCV) and relative to TTW, agreement was moderate for the NS and NPS, and good for BAL.

Conclusions: Agreement between TTW and other sampling methods differed for different pathogens. For bacterial pathogens, agreement was very good for NS, NPS, and BAL. For BRSV and BCV, results of BAL agreed best with the TTW.

An atypical case of cutaneous and respiratory actinobacillosis in a French beef cattle herd

Anne Relun ¹Nora Cesbron ¹Patrick Bourdeau ²Laëtitia Dorso ¹Alain Douart ¹Thomas Brement ²Christophe Chartier ¹Sébastien Assié ¹Henrik Christensen ³Raphaël Guatteo ¹

¹Farm Animal Medicine Unit, LUNAM Université, ²Parasitology, Dermatology and Mycology Unit, LUNAM Université, Oniris, Nantes, France, ³Department of Veterinary Disease Biology, Faculty of Life Sciences, University of Copenhagen, Frederiksberg, Denmark

Objectives: Actinobacillosis is a worldwide infectious disease due to *Actinobacillus lignieresii*, generally considered as a sporadic condition typically involving the tongue ("wooden tongue") and draining lymph nodes in cattle. We present here another and very different clinical pattern.

Materials and Methods: Two "Rouge-des-Prés" beef cattle from a single herd were referred with a common history of chronic evolution of a severe dermatosis affecting, and limited to, hind legs. The general examination revealed cachexia, signs compatible with pneumonia, regional lymphadenitis and burst abscess in the udder of one cow. Cutaneous signs were characterized by multiple single to coalescent cutaneous and subcutaneous nodules (0.5 to 10 cm in diameter), some of them ulcerated with crusts. It was combined with massive swelling of the affected limbs and numerous releasing pus fistulae. The differential diagnosis included first a cutaneous infection due to an Actinomycetes organism or possibly another group of bacteria secondary to a primary parasitic (Besnoitia or leg mange), deep fungal or viral (lumpy skin disease) aetiology.

Results: Direct smears using rapid stains were inconclusive and no parasite was observed in multiple skin scrapings. Fungal cultures were negative. Two series of biopsies were performed and histopathological examination revealed chronic, diffuse, severe pyogranulomatous dermatitis, associated with Splendore-Hoeppli phenomenon Gram-negative bacteria and minute bacterial grains compatible with mycetoma/pseudomycetoma. Special stain (Ziehl-Neelsen) was negative for *Mycobacterium* spp.. Poxviruses PCR was negative. Cultures from skin, lymph nodes and lungs (both cows were euthanized for welfare reasons) identified a Pasteurellaceae organism, confirmed as *Actinobacillus lignieresii* by partial sequencing of the *rpoB* gene with 99.4% DNA similarity to the type strain of the species. Two strains sequenced from the herd with origins in pus from a cutaneous nodule and a mammary lymph node, respectively showed 99.4% DNA similarity indicating that the infection in the herd was not related to a single clone.

Conclusions: One other similar case was observed in the same herd suggesting a pseudocontagious, likely environmentally induced, condition, thus illustrating that widely distributed organisms like *Actinobacillus* may be associated to non-classical clinical presentation.

A Likely Case Of An Outbreak Of Theileriosis In Simmental And Holstein Heifers: First Report In Colombia

Olimpo Oliver¹*Rubiela Castañeda²

¹Animal Health, National University of Colombia, ²Microbiology, Pontificia Universidad Javeriana, Bogota DC, Colombia

Objectives: The objective of this study is to present the first report of a likely outbreak of bovine theileriosis which is an exotic disease in Colombia and to describe the clinical features observed as well as the treatment implemented.

Materials and Methods: Two 22 month-old pregnant Holstein and Simmental heifers that weighed 380 Kg were referred to the Large Animal Clinic at the National University of Colombia with history of depression, pigmenturia and dark feces. They were treated with oxytetracycline, diminazene, vitamin B and flunixin meglumine. The heifers came from a farm with animals of different breeds on pasture and supplemented with

concentrate and corn silage. 20 days before admission, a Simmental adult cow and a heifer with similar clinical signs were treated with oxytetracycline/imidocarb and died within 2 days despite treatment. Hematological evaluation requested by the referring veterinarian of other Zebu cattle showed PCV values between 20 - 22% and the blood smears revealed the presence of *Babesia* spp in 30% of the heifers and 50% of the female calves, fecal exams revealed low parasite burden and no diarrhea was observed.

On clinical examination, the heifers were in recumbency, unable to get up, had low body condition score (2/5), sunken eye bulbs (15 mm), severe dehydration (10-12%), pale and icteric mucous membranes, weak pulse, increased capillary refill time (5"), tachycardia (86 and 160 BPM), tachypnea (16 and 52 breath per minute), hypothermia (36.7°C), and in one animal, ruminal atony, pigmenturia, increased paralumbar lymph nodes were observed. Rectal palpation of both patients indicated lack of feces and collapsed rumen. Ticks were observed also on both patients. Venous blood was collected for CBC, serum biochemistry and blood gases; urine was sent for urinalysis and an ECG was done on one heifer.

Results: CBC showed a severe anemia in both animals (PCV: 9 and 10%), hypoproteinemia and lymphopenia. In both cases, microscopic structures compatible with *Theileria* spp. were observed in high numbers in lymphocytes and red cells and neither *Babesia* spp. nor *Anaplasma marginale* were observed. Serum chemistry tests showed increased urea, AST, Cl⁻ and lactate levels in both heifers as well as a decrease in K⁺, ionized Ca⁺⁺, Glucose and tCO₂; only one heifer showed increased GGT and Na⁺. Blood gases and electrolyte evaluation showed hyperchloremic and lactic acidosis. Urinalysis revealed aciduria, hemoglobinuria and proteinuria. ECG on the Holstein heifer indicated a ventricular tachycardia.

Both cases were treated with 7.5% hypertonic saline solution, isotonic saline to treat dehydration and 5% NaHCO₃ solution to correct acidosis. To treat the hemolytic anemia blood transfusions were performed. Calcium borogluconate was administered to correct the hypocalcemia and flunixin meglumine as antiinflammatory medication. To treat the theileriosis a combination of oxytetracycline and diminazene was administered several times given that no buparvaquone is available in Colombia. The ventricular tachycardia was corrected using IV lidocaine and vitamin B complex was used as hematinic. To treat the *Boophilus* spp. tick infestation ivermectin was given and ruminal transfaunation was performed to stimulate appetite. After these therapies, hematological, serum and acid base values returned to physiological ranges. The two heifers were discharged from the clinic 29 days after admission.

Conclusions: In conclusion, it is a very likely outbreak of Theileriosis in Holstein and Simmental heifers and the first report of this exotic disease in Colombia and given the clinical features, it may have been caused by *Theileria orientalis*.

Internal Medicine

P03-003-115

Maternal, Fetal And Neonatal Heart Rate And Heart Rate Variability Assessment In Holstein Cattle

DARIO CEDENO¹*Maria Lorencó²Carmen A. Daza²Carla Ulián³Simone Chiacchio³ and Dario A. Cedeno_Quevedo, PhD; Maria L. G. Lourenço, PhD; Carmen A. Daza, MSc; Carla M. V. Ulián, Simone B. Chiacchio, PhD

¹Universidad de Nariño, Pasto, Colombia, ²UNESP, Botucatu, Brazil, ³Animal Health, UNESP, Botucatu, Brazil

Objectives: Fetal heart rate monitoring not only enables verification of fetal health and viability, but also provides information about the stage of development of the autonomic nervous system. Thus, the aim of the work was to determine values in heart rate and heart rate variability in Holstein cows, her fetus and neonates.

Materials and Methods: The study was design to be descriptive of continuous fetomaternal and neonatal electrocardiogram recordings during perinatal and neonatal period. In the study, 23 healthy pregnant Holstein cows and 18 neonates were used. The electrocardiograms were registered during the period from May to November 2014. This project had the approval of the Ethics Committee on Animal Use - CEUA and signing the informed consent by the owner of the farm. Heart rate (HR) and heart rate variability (HRV) were assessed by fetomaternal electrocardiography (ECG). The electrocardiographic examinations followed a pattern of repetitions over time at pre-defined times. Fetomaternal recordings were conducted in six pre partum moments; 35, 28, 21, 14, 7 and 1 day, and in neonates six moments; 35, 28, 21, 14, 7 and 1 day after calving. Heart rate, time domain variables; the mean beat-to-beat interval (RR interval), its standard deviation (SDNN), and the root mean square of successive RR differences (RMSSD) and frequency domain variables; low frequency (LF), high frequency (HF) and ratio LF/HF of heart rate variability were analyzed. Changes over time were analyzed using a general linear model for repeated measures. A p value < 0.05 was considered significant. All data given are means ± SEM.

Results: No significant changes in maternal and fetal RR interval and HR were found. In fetus, SDNN decreased significantly from 38. 0.8 ± 2. 6 ms to 28. 9 ± 2. 4 ms (p < 0.05), while RMSSD did not reach statistical significance. Fetal heart rate and interval RR differs statistically from one day before delivery (163± 7. 5 bpm; 381±24. 2 ms) and the day after calving (131± 5 bpm; 472± 16. 2 ms). Variables in time (SDNN and RMSSD) and frequency (LF and HF) domain presented a significantly difference (p < 0.05) from fetal to neonatal stage.

Conclusions: Fetomaternal ECG is a reliable technique to detect cardiac signals in bovine fetuses in the last 35 days of gestation. In the last week of gestation, reductions in the fetus values of SDNN and RMSSD reflect a shift towards more sympathetic dominance. After calving, the increased in high frequency and decreased in low frequency indicate activation of the vagal nerve on the heart and respiration modulation.

Internal Medicine

P03-003-116

Potassium Concentrations In Plasma, In Erythrocytes And Muscle Tissue In Cows With Decreased Feed Intake And Gastrointestinal Ileus

Thomas Wittek¹Anja Müller²Stephanie Schneider^{1*}

¹Vetmeduni Vienna, University Clinic for Ruminants, Vienna, Austria, ²Vet Med Labor GmbH IDEXX Laboratories, Ludwigsburg , Ludwigsburg, Germany

Objectives: This method however may not be able to provide information about the intracellular potassium pool. The aims of the study were to evaluate the potassium metabolism by comparing the extracellular and intracellular potassium concentration in cows with reduced feed intake and gastrointestinal ileus and to determine the association between these two. Further the study aimed to investigate if cows with reduced feed intake suffer from potassium depletion or simply shift potassium between intra and extracellular space.

Materials and Methods: Twenty cows between day 1 and 3 days post partum and 20 cows with gastrointestinal ileus were included in the study. The cattle were Simmental and Holstein-Friesian cows. Venous blood was taken and plasma potassium concentration was measured using an ion sensitive electrode. A muscle sample of the gluteal muscle was taken by biopsy using a Bergstroem needle. Intracellular potassium concentration was measured in erythrocytes and muscle cells applying inductively coupled plasma optical emission spectroscopy.

Results: The diet of cattle contains large amounts of potassium therefore in cattle with undisturbed feed intake potassium is abundantly available. However, a decreased feed intake may result in hypokalemia. The routine method to evaluate potassium metabolism is the measurement of the extracellular potassium concentration in plasma or serum. Postpartal cows did not show hypokalemia, cows with gastrointestinal ileus were hypokalemic (2.9 mmol/l ± 0.78). Some of the hypokalemic cows showed muscle tremor, but no other signs of paralysis were observed. There was no difference of potassium concentrations in erythrocytes and muscle tissue between hypokalemic and normokalemic cows. Intracellular potassium in erythrocytes varied very widely; cows post partum: 3497 to 10735 mg/kg, cows with ileus: 4139 to 21678 mg/kg. Potassium in muscle tissue did not differ between both groups. No association between extracellular and intracellular potassium concentrations could be found.

Conclusions: The results of the study indicate that measurement of plasma potassium concentrations is not suitable to evaluate potassium metabolism. In addition to extracellular potassium measurement muscle tissue potassium is needed to provide information about the intracellular potassium pool. Since other factors like blood groups influence potassium concentrations in erythrocytes these cells although easily obtainable are not suitable to measure intracellular potassium concentrations. Acute decrease of feed intake as it is the case in cows with ileus does not result in immediate potassium depletion but in a hypokalemia.

P03-003-117

Evaluation of abomasal, urinary and fecal pH, blood gas and chlorine ions in healthy sheep treated with oral omeprazole, preliminary data.

Carolinne Broglio Deusdado^{1*}Aline A. Morgado¹Priscilla M. Nascimento¹Débora D. Carvalho¹Marcela R. Faria¹Maria Claudia A. Sucupira¹

¹Universidade de São Paulo, São Paulo, Brazil

Objectives: Abomasal ulcers often are unnoticed by farmer and veterinarians due the mild clinical manifestations and due the little available diagnostic resources. When the diagnosed is already established or there is clinical suspicion, the treatment is also restricted. Although studies are limited and there is no indication for ruminants, oral omeprazole often is used in veterinary hospitals to treat and / or prevent abomasal ulcers in these species. The objective of this study was to evaluate the effect of omeprazole in healthy sheep by physical examination; abomasal, urinary and fecal pH; blood gas and chlorine ions.

Materials and Methods: Five adult healthy sheep, males, castrated, average weight of 45 kg, with abomasal cannula were used. The animals were allocated in individual stalls and were fed a diet with hay and commercial concentrate in the proportion 80:20. Water was available ad libitum for intake and feed offered in 3% of body weight on a dry basis.

The animals were randomized in two groups. One group received oral omeprazole in the form of paste, at a dose of 4mg / kg every 24 hours for seven days and the other was untreated. The experimental design was cross-over type, with a washout period of seven days.

Physical exams and collections were performed in the morning on seventh day when sheep were fasted for 12 hours. Samples of faeces, urine and abomasal content were immediately subjected to the determination of pH. Blood samples were collected by jugular vein puncture for immediate determination of chloride, blood pH, concentration of bicarbonate (HCO₃) and base excess (BE).

Results: The use of oral omeprazole for seven days in sheep did not influence the abomasal pH (P = 0.357), urinary pH (P = 0.2963) and fecal pH (P = 0.678). There was also no significant effect on blood gas parameters. There was no effect on blood pH (P = 0.416), HCO₃ content (P = 0.8345) and base excess (P = 0.9168). Although also not statistically significant differences between sheep treated with omeprazole and control sheep, in physical examination there was a trend (P = 0.110) lower respiratory rate to those treated with omeprazole. There were no differences between groups for heart rate (P = 0.4647).

Conclusions: In healthy sheep the omeprazole administration at a dose of 4 mg / kg every 24 hours for seven days was not effective in increasing the pH abomasal. This drug not change the other parameters analyzed at the moment.

Hematologic differences between calves and lactating dairy cows in Poland

Olga Aniolek¹; Zdzisław Gajewski¹; Monika Petrajtis-Gołobów¹; Przemysław Zych²; Małgorzata Wielgosz¹

¹Department of Large Animal Diseases with the Clinic, ²Warsaw University of Life Sciences, Department of Large Animal Diseases with the Clinic, Warsaw, Poland

Objectives: Change in hematologic reference range in association with age have been described in cows. The purpose of this study was to determine whether CBC counts differ between calves and lactating dairy cows.

Materials and Methods: In this retrospective study, twenty clinically healthy calves were sampled for CBC. The calves included 14 males and 6 females. They were born between September and October, 2015. The blood were collected from the jugular vein into tubes containing K3EDTA (Venoject, Terumo, Leuven, Belgium). CBC data and total solids were compared between calves and lactating dairy cows (Mindray BC 2800 vet). Reference intervals were determined for 20 lactating dairy cows of the same breed.

Results: Twenty calves and twenty lactating dairy cows fitted the criteria for inclusion in the study. There was no evidence of a difference in sex frequency between calves or clinics. Calves had lower mean corpuscular volume (MCV), packed cell volume (PCV), red blood cells (RBC) count. There were marked differences in the distribution of hematocrit (HCT) and hemoglobin concentration (Hg) concentration between clinics (P<0,05). There were statistically significant but clinically unimportant differences in differential white blood cells (WBC) counts.

Conclusions: Compared with lactating dairy cows, calves have lower PCV, MCV, HCT, RBC count and HGB concentration. It is important

to be aware of such veterinarians when interpreting CBCs in calves to avoid misdiagnosis and unnecessary further diagnostic or treatment.

Spinal Lymphosarcoma in a Dairy Heifer: A case report

Kristina R. Mueller¹; Ali Huang¹; Keren Dittmer¹

¹IVABS, Massey University, Palmerston North 4442, New Zealand

Objectives: The clinical and histopathological findings in a one-year-old Kiwi cross dairy heifer with compression of the spinal cord resulting from infiltration of a lymphosarcoma from the thoracic lymph nodes through the spinal nerve roots are described.

Materials and Methods: The heifer presented with paraparesis and apparent loss of body condition after being down on pasture for an unknown amount of time. On physical examination, reduced pain sensation in the pelvic limbs was evident, however a crawling forward motion could still be carried out. No hip, spine or limb asymmetry could be found, and all palpable superficial lymph nodes were within normal limits. Clinical biochemistry revealed mildly increased creatine kinase activity while electrolyte concentrations were within reference ranges. Despite symptomatic treatment with oral fluids and anti-inflammatories the heifer remained recumbent for four days, and was subsequently euthanized due to poor prognosis.

Results: On post-mortem examination, a large mass surrounded the vertebral bodies of the thoracic vertebrae (T) 10 to 13. The mass infiltrated the spinal canal via the spinal nerve roots, resulting in compression of the spinal cord. No bone lysis was present. A firm mass (5 cm x 5 cm x 10 cm) was also present on the right side of the rib cage. Numerous thoracic lymph nodes along the vertebral column were severely enlarged while the abdominal lymph nodes were mildly enlarged. Histopathological findings included severe wallerian degeneration with swollen axons in the spinal cord, and the thoracic and vertebral masses consisted of a monomorphic population of large lymphoblasts, consistent with lymphosarcoma.

Conclusions: Lymphosarcoma is an uncommon tumour of cattle, but a peak in incidence does occur in yearlings. A variety of clinical and paraclinical tests are often needed to establish a diagnosis of bovine leucosis, however lymphosarcoma should be included in the list of differential diagnoses for young cattle that present with paraparesis.

P03-003-120

Idiopathic pseudo pericarditis in Kangeyam bullocks – a clinical study

Muthusamy Ranjithkumar¹; Mani Saravanan¹; Rajamohan Saahithya¹; Ramasamy Ravi¹

¹Teaching Veterinary Clinical Complex, Veterinary College and Research Institute, Orathanadu, Thanjavur, India

Objectives: The term pseudo pericarditis has been used to describe similar symptoms of traumatic pericarditis caused by tumours, abscesses, echinococcus cysts, swollen lymph nodes resulting from tuberculosis and leukosis, one-sided pleuritis and diaphragmatic hernia. Because of the anatomic compactness of thorax and abdomen the pericarditis is rarely reported in *Bos Indicus* bullocks. This may be the first report in pseudo pericarditis in Kangeyam bullocks in India. This clinical report describes the clinical signs, diagnosis, treatment and clinical outcome in two cases.

Materials and Methods: This research was carried out at Teaching Veterinary Clinical Complex (TVCC), Veterinary College and Research Institute, Orathanadu – 614 625, India during October 2014 to December 2014. Two work bullocks bearing institutional case numbers 6636/14 & 6706/14 were reported with history of brisket and dewlap edema, anoxia, cessation of rumination, debility and admitted in large animal outpatient unit of TVCC. On clinical examination the animal had high temperature, engorgement of jugular vein, enlarged prescapular lymphnodes and ruminal atony. Survey radiography (Siemens, 320mA, high frequency machine with computed radiographic system) was taken to rule out the possibility of traumatic pericarditis. The complete blood count was carried out in automated hematology analyzer (Vet scan HM5, Abaxis) on every fourth day. Serum biochemistry was carried out in semi automated analyzer. Abdominocentesis was carried out in one animal (6636/14) and not in another (6706/14) because of owner's non-compliance. Both the animals were treated with Oxytetracycline antibiotic @ 20 mg/kg along with diuretics like frusemide @ 5 mg/kg, polyionic fluids like multiple electrolyte solution, ringer's lactate, 7.5% sodium bicarbonate, ruminatorics and B-vitamins. In both the animals rumen gut transplantation was attempted. Acetic acid-chalk paste was applied topically. Owners were advised to report any untoward reactions in animals.

Results: It was observed that *Bos Indicus* working Kangeyam bullocks were the most commonly affected by this disease than cross bred *Bos taurus* cattle. Similar observations were noted (personal communication) by veterinarians in the field. The clinical signs are anorexia from day one onwards, ruminal atony and cessation of rumination, dehydration, dull and depressed, fever, brisket edema which extends up to inter-mandibular region, jugular vein enlargement and enlarged prescapular lymphnode. The degree of dehydration was severe (7-9%). On cardiac auscultation the heart sounds were normal. Survey radiography revealed normal cardiac silhouette. There was a marked leukopenia and lymphopenia without neutrophilia on day one in both the animals. Shortly this turned to leukocytosis and lymphocytosis. There was a marked increase in globulin fraction with altered A:G ratio. Peritoneal fluid analysis ruled out the absence of traumatic peritonitis. Appetite was improved after 15 days of therapy (6636/14) along with rumination and after 10 days in another animal (6706/14). Complete recovery was noticed 20 and 15 days after therapy in 6636/14 & 6706/14 animals respectively

Conclusions: This clinical study concludes severity of pseudo pericarditis due to idiopathic origin possibly of increase in preload. The major clinical signs were brisket and dewlap edema, jugular enlargement, fever, anorexia, cessation of rumination, ruminal atony and inanition. Loop diuretic such as frusemide which decrease preload along with broad spectrum antibiotics, adequate fluid and electrolytes, sodium bicarbonate, gut transplantation, will help in clinical recovery of pseudo pericarditis animals.

Efficacy of intravenous hypertonic saline solution in the treatment of experimentally induced neonatal diarrhea in buffalo calves

Muhammad Arif Zafar ¹, Ghulam Muhammad ², Arfan Yousaf ¹, Murtaz Hasan ³

¹Clinical Sciences, Arid Agriculture University, Rawalpindi, ²Clinical Medicine and Surgery, University of Agriculture, Faisalabad,

³Pathobiology, Arid Agriculture University, Rawalpindi, Pakistan

Objectives: This study was conducted to determine the safety and efficacy of hypertonic saline solution (HSS) in the amelioration of hemodynamic parameters and other laboratory variables especially metabolic acidosis in buffalo calves with experimentally induced neonatal diarrhoea with *Escherichia coli*.

Materials and Methods: Twelve 5-8 days old healthy male buffalo calves (30–40 kg body weight) were instrumented under halothane anesthesia to permit hemodynamic parameters and collection of blood samples to observe different variables. Neonatal diarrhea was induced through oral administration of 2 ml broth culture of having enteropathogenic *Escherichia coli* count of 10¹⁰ CFU dissolved in 250 ml of normal saline solution. Calves were then randomly assigned to receive either isotonic saline solution (ISS; group A) @ 32 ml/kg BW or HSS (group B) @ 4 ml/kg BW. Hemodynamic parameters and other laboratory variables were monitored for 72 hours.

Results: Administration of hypertonic saline solution (group B) immediately corrected metabolic acidosis (base excess [BE] > -15 mM), restored mean arterial pressure and expanded the plasma volume more rapidly in calves of group B and showed significant difference (P < 0.05) over group A. Hypertonic saline treated calves had higher cardiac index after 1 hour of administration as compared to ISS treated calves and showed significant (P < 0.05). Administration of HSS also improved blood gases more rapidly and efficiently in calves of group B.

Conclusions: On the basis of findings of this study, it was concluded that hypertonic saline solution can be safely administered to the buffalo calves with neonatal diarrhea. It offset deleterious hemodynamic effects and provides a practical and economical method to resuscitate dehydrated calves with neonatal diarrhea associated with *E. coli*.

Diagnosis of acute tubular necrosis secondary to *Amaranthus retroflexus* poisoning in cattle using urinalysis, fractional excretion and electrophoresis

Nicolas Herman ¹, Catherine Trumel ², Gilles Meyer ¹, Francois Schelcher ^{1,3}

¹Ruminant section, Department of Livestock and Products – Veterinary Public Health, ²INP-ENVT College of Veterinary Medicine of Toulouse - France, ³UMR1225 IHAP, INRA-ENVT, Toulouse, France

Objectives: Acute decline in kidney functions, also called Acute Kidney Injury (AKI), results in retention of nitrogenous (urea and creatinine) and non-nitrogenous waste products. The most common causes of AKI in bovine practice are prerenal (hypovolemia), and Acute Tubular Necrosis

(ATN) due to the damaging effect of toxins to renal tubular cells. In contrast to the companion animal species, few data are available in bovine on the most interesting biomarkers for characterization of AKI. The present report describes implementation of urinary and plasma biomarkers to achieve diagnosis of ATN caused by *Amaranthus retroflexus* poisoning.

Materials and Methods: Four sick adult cows (Blonde d'Aquitaine breed) were referred to the National Veterinary School of Toulouse because a history in the herd of unexplained sudden death in pasture. Clinical examination was performed and urine was obtained by bladder catheterization from each cow. Standard analysis was performed on urine and plasma (Li-heparinate, Vitros350, Ortho Clinical Diagnosis, England) using a chemical analysis with urinary strip (URIVET-100, Kitvia, France) completed by a Heller's test (nitric acid) to detect proteinuria, by Urine Specific Gravity (USG) estimation via refractometry and by unstained sediment examination. Additionally, Urine Protein / Creatinine ratio (UPC), fractional excretion of sodium ($FeNa = [(U Na * P Creat) / (P Na * U Creat)] * 100$), fractional excretion of urea ($FeUrea = [(U Urea * P Creat) / (P Urea * U Creat)] * 100$) were calculated using biochemical urine results (Kbio2, Kitvia, France). Urine protein electrophoresis on sodium dodecyl sulfate-agarose gel (SDS-AGE) was simultaneously performed.

Results: At first examination, clinical signs were anorexia, paresis, bradycardia, dark diarrhea and an expired breath smelling ammoniac. Plasma analyses revealed a severe azotemia (creatinine between 1692 and 2593 μ mol/L), with hyperphosphatemia (between 2.25 and 5.21 mmol/L) and hypocalcemia (between 0.95 and 2.24 mmol/L), which, in combination with the clinical signs, suggested an AKI. To distinguish prerenal impairment from kidney injury, urine analyses were further performed. Urinary strips were consistently positive for protein, glucose and peroxidase activity but Heller's test was positive in only two of the four cases. Urine pH was in the normal ranges, while the USG was low, near isosthenuric. Free Renal Tubular Epithelial Cells (RTEC) and Renal Tubular Epithelial Cells casts or granular casts were detected on unstained sediment of urine. Urinary biochemistry revealed an increased sodium concentration (between 48 and 97 mmol/L), an increased UPC (between 1.30 and 2.70, canine reference value < 0.5), an increased FeNa (between 8.7 and 55.1%, bovine reference value < 1%) and an increased FeUrea (between 83 and 120%, human reference value < 35%). Urinary protein electrophoresis revealed low molecular weight proteins consistent with tubular damage. All these findings were highly suggestive of an ATN. Three of the four cows died and were necropsied. Microscopic lesions of kidney confirmed the diagnosis of ATN. A toxicological analysis of the rumen contents of the dead cows, combined with a pasture inspection, demonstrated that the ATN was associated to *A. retroflexus* ingestion.

Conclusions: AKI secondary to an acute tubular necrosis associated with *Amaranthus retroflexus* ingestion was confirmed by histopathological and toxicological results. The reported cases illustrate the value of the combination of urinalysis, fractional excretion of sodium, urine protein / creatinine ratio and urine electrophoresis for the diagnosis of ATN. Future research should focus on the establishment of specific thresholds for urinary biomarkers in cattle medicine.

Polyarteritis nodosa in a three year old Belgian Blue cow

Bonnie Valgaeren¹Alida Tavenier¹Laura Van Driessche¹Linde Gille¹Leslie Bosseler²Koen Chiers²Piet Deprez¹Bart Pardon^{1*}

¹Internal medicine and clinical biology of the large animals, ²Pathology,

Bacteriology and Avian Diseases, Ghent University, Merelbeke, Belgium

Objectives: Polyarteritis nodosa, also known as Kussmaul disease, is a systemic vasculitis of small- or medium-sized muscular arteries, typically involving renal and visceral vessels but sparing the pulmonary circulation. The objective of the present study was to describe a case of polyarteritis nodosa in an adult cow.

Materials and Methods: A 3-year old female Belgian Blue cow was presented with the complaint of weight loss, fever and diarrhea since 4 weeks. The cow gave birth to a healthy calf via cesarian 3 months prior. The cow had been treated with antibiotics, NSAID's, and imidocarb at home without improvement. Clinical examination, blood examination, ultrasound, urine analysis, autopsy, bacteriology and histology of the heart, liver, intestine, kidney, brain, spleen, lung, pancreas and lymph nodes were used in the diagnostic work-up of this case.

Results: Clinical examination revealed cachexia, mild fever (39,2°C), severe diarrhea, congested mucosae and dehydration. On biochemical analysis total protein and kidney-values were normal, but gamma-glutamyltransferase (GGT) was severely elevated (> 952U/L, reference value 0-80U/L). Aspartate aminotransferase (AST), alkaline phosphatase, lactate dehydrogenase (LDH), creatine kinase (CK), and total bilirubin were mildly elevated. Blood gas analysis showed a mild metabolic alkalosis and the ionogram revealed hypokaliemia. Hematology was normal. Serology for *Fasciola hepatica* and Johne's disease were negative, as was antigen ELISA for bovine viral diarrhea (BVD). Ultrasound of the thorax revealed a more hyper echogenic aspect of the liver. Urine analysis showed no abnormalities. The cow was euthanized due to poor general condition. The main conclusions from necropsy were diffuse catarrhal enteritis, dehydration and cachexia. The liver showed mild rounded edges, but no other gross abnormalities. The heart had several subendocardial white necrosis spots. Bacterial swabs from the jejunum and mesenteric lymph nodes were polybacterial. Histology of the liver showed a mild fibrosis around the smaller bile ducts, as can be seen in fluke-infestation. The lamina propria in the intestine was infiltrated with mainly eosinophils and some lymphocytes and plasma cells, indicating an eosinophilic enteritis. The arterial wall from several big arteries in the heart, liver and kidney were infiltrated by mainly lymphocytes and plasma cells, and some neutrophils, indicating polyarteritis nodosa.

Conclusions: Polyarteritis nodosa arises when pathogenic agent damage the arterial wall, which leads to the activation of the Hageman factor. This will cause vasculitis, with chemotaxis of neutrophils, increased permeability, fibrosis, thrombosis and necrosis. The only confirmed cause of polyarteritis nodosa is hepatitis B in humans. In cattle, bovine malignant catarrhal fever (BMCF), BVD and sarcosporidiosis have been suggested as potential causes for polyarteritis nodosa. However, there were no signs of these diseases in this animal. The chronic presentation of the polyarteritis nodosa impedes the possibilities of identifying the primary etiology.

Simultaneous outbreak associated with Bovine herpesvirus-5 and *Histophilus somni* in feedlot cattle from Southern Brazil

Selwyn Headley^{1*}Luciana C. Balbo¹Gustavo R. Queiroz²Thalita E. S. Oliveira¹Juliana T. T. Fritzen¹Jéssica R. Moreira¹Alice F. Alfieri

¹Júlio A. N. Lisboa ²Amauri A. Alfieri ¹

¹Department of Veterinary Preventive Medicine, ²Department of Veterinary Clinics, Universidade Estadual de Londrina, Londrina, Brazil

Objectives: Bovine herpesvirus-5 (BoHV-5) is endemic in cattle herds from Brazil and is one of the principal causes of neurological disease. Histophilosis is a disease complex that is caused by the gram negative bacterium *Histophilus somni* (formerly *Haemophilus somnus*). Alternatively, several pathological syndromes associated with this pathogen were recently identified in cattle from different geographical regions of Brazil. The objectives of this study were to investigate the causes of an acute outbreak of cattle mortality associated with acute neurological manifestations in a feedlot located in Southern Brazil.

Materials and Methods: The owner of a feedlot located in a rural district that is approximately 200 km distant from the city of Londrina, Paraná, Southern Brazil, reported the sudden death of nine yearlings after a brief onset of neurological manifestations. This feedlot acquires cattle for fattening from several geographical regions of Brazil, and at the time had approximately 1200 animals, but the affected yearlings were in a group of 150. Tissue fragments (brainstem, thalamus, cerebrum, cerebellum, and the trigeminal nerve ganglion and the carotid rete mirabile complex [TGN-CT]) from two yearlings (animal 1 and 2) were received in duplicate for pathological and molecular analyses. Animal 1 was euthanized in extremis, while the other yearling died spontaneously. Samples were processed for routine histopathological evaluation and used in PCR and RT-PCR assays designed to detect principal infectious agents associated with neurological disease of cattle from Brazil. These PCR assays targeted specific amplicons of the glycoprotein C gene of bovine herpesvirus type 1 (BoHV-1) and -5, and the 5'-UTR region of the bovine viral diarrhea virus, the listeriolysin gene of *Listeria monocytogenes*, the 16s rRNA gene of *Histophilus somni*, and the tegument protein gene of ovine herpesvirus type 2 (OvHV-2). Positive and negative controls were included in all PCR and RT-PCR assays. Further, brain samples were submitted for the identification of *Lyssavirus*

Results: Clinically, there was profuse salivation and muscular spasms (animal 1) and motor incoordination (animal 2); the time between the onset of clinical manifestation and euthanasia/death was three days. Further, most neurological manifestations were observed approximately 30 days after arrival of the animals at the feedlot. Significant gross pathological alterations were not observed in the tissues received for pathological analysis from both animals. However, histopathology revealed two distinct neuropathological patterns in several neuroanatomical regions of the brain of both cows: a) moderate multifocal nonsuppurative meningoencephalitis with vasculitis and perivascular cuffings, b) and thrombotic encephalitis with infarction and neutrophilic exudation. These alterations being more pronounced in animal 1, while there was severe perivascular hemorrhage in animal 2. Fibrinoid necrosis was not observed in any tissue evaluated. The BoHV-5 and *H. somni* PCR assays amplified the specific genes of each agent from in both animals: BoHV-5 was successfully amplified from the cerebellum, TGN-CT, and brainstem of both animals and the thalamus of animal #1, while *H. somni* DNA was amplified from the brainstem (animal 1) and thalamus (animal 2). All other PCR/RT-PCR assays yielded negative results, and rabies virus was not identified.

Conclusions: The neuropathological patterns observed in several regions of the brain of these yearlings are consistent with infections due to BoHV-5 (nonsuppurative meningoencephalitis) and *H. somni* (thrombotic encephalitis). Further, the amplification of nucleic acids of these two agents from neurological regions of the brain with histopathological evidence of disease confirmed the participation of these pathogens in these lesions, resulting in coinfections due to BoHV-5 and *H. somni*. Consequently, these infectious agents were associated with the development of the neurological disease outbreak in cattle at this feedlot.

CASE STUDY: Bovine leukemia virus in a dairy herd of Mexico

Eduardo Posadas ¹, Silvia Peña ², Viridiana Martínez ³, Teresa Lopez ⁴, Mario Bedolla ⁵, Rosa Elena Sarmiento ⁴

¹Departamento de Medicina y Zootecnia en Rumiantes, FMVZ-UNAM, ²Departamento de Toxicología, UAM Xochimilco, Coyoacan, ³FMVZ-UNAM, Mexico City, Mexico, ⁴Departamento de Microbiología e Inmunología, FMVZ-UNAM, ⁵Departamento de patología, CAITSA, Mexico City, Mexico

Objectives: Enzootic bovine viral (LVB) is an infectious disease of cattle caused by a lymphotropic virus present in several countries. Courses in chronic infection and asymptomatic form. In seropositive animals is persistent lymphocytosis and occasionally tumors in the uterus, heart, abomasum and lungs. The aim of this study is to confirm the clinical diagnosis of bovine viral leucosis by hematological, molecular and histopathology tests

Materials and Methods: Two clinical case presented is of a cow Holstein Friesian 4 years old, with a history of abortion and low milk production, weight loss, depression, cough and moist rales with presumptive diagnosis of pneumonia. General physical examination was performed finding all normal constant, slightly pale mucous membranes, lymph node chain slightly increased left size and when listening to the lung fields moist rales and cough were found, with a presumptive diagnosis of pneumonia treatment was established based enrofloxacin at a dose of 5-10 mg per kg body weight, once a day for 5 days. However, clinical signs of cough, moist rales, jugular positive pulse palpation and rectal tumors were detected in utero were found changing to a second presumptive clinical diagnosis of viral bovine leukosis. Blood samples were sent to the Diagnostic Laboratory of Pathology of the Agricultural and Industrial Center of Tizayuca, Hidalgo, Mexico, and the Laboratory of Virology, School of Veterinary Medicine (FMVZ) of the UNAM for CBC and insulation LVB virus by PCR.

Results: The results obtained in the above Laboratories, normocytic hypochromic anemia, leukocytosis, lymphocytosis and monocytosis, and LVB virus positive by PCR respectively found. After fifteen days of the clinical presentation of the case, the cow died. At necropsy multicenter metastases heart, lung, rumen, abomasum, intestines and uterus lymphoma was observed. In the histopathological findings they were found with lymph node tissue and encapsulated neoplasm delimited by round neoplastic cells in mesentery, uterus and heart.

Conclusions: You must have a tight control on the purchase of animals and keep them in preventive quarantine in addition to the tests for brucellosis, tuberculosis and other diseases and abortion with LBV, once identified infected cows should separate healthy animals and calves must be fed negative mothers milk. Routine clinical and reproductive management must be performed with hygiene. Furthermore, the reusable material as applicators for insemination, surgical equipment or instruments to dehorning or aretado be disinfected or sterilized before use. Finally it should be insect control and also constitute a transmission path.

Epidemiology And Risk Factors Of Pyelonephritis In Israeli Dairy Cattle

Tamir Goshen^{1,2} Dalia Solomon³ Nahum Shpigel³¹Koret Veterinary School, Heberew university, Rehovot, ²Hachakalit, Gedera, ³Heberew university, Rehovot, Israel

Objectives: The main objective of the study is to define the risk of pyelonephritis associated with urine sampling via urethral catheterization; the secondary objectives are to describe the current epidemiology and define other risk factors for pyelonephritis in Israeli dairy farms.

Materials and Methods: The research is a retrospective case control study, which was conducted on lactating cows that calved between July 2006 and June 2013 in three commercial herds consisting of 250-450 Israeli Holstein dairy cows. The diagnosis of pyelonephritis was based on clinical manifestation of the disease as reported before. Shortly, all cows went through a comprehensive clinical examination including rectal palpation and urine extraction via urethral catheterization. In part of the cases the urine was sampled using an aseptic catheterization technic, and 10-20 ml urine sample was collected into a sterile 30 ml vial. The urine sample was refrigerated and sent for urine analysis and bacterial culture up to 48 hrs from sampling. Treatment of the animals was initiated at diagnosis and altered, if necessary, according to bacteriological findings and antibiogram. Computerized data were retrieved from the herds and the Israeli herd book, and analyzed using Excel (version 2010, Microsoft, Redmond, WA) and SPSS (version 19, IBM Business analytics, NY USA). Lactation Incidence Risks for all recorded calving diseases and culling data were evaluated for healthy control cows and for pyelonephritis cases. For multivariate analysis two models were built: a multivariate logistic regression using the binary logistic regression function for the general population, and conditional logistic regression using the cox survival analysis function for the case control study. The final models were built with exit criteria set at $P > 0.10$, values of $P < 0.05$ were considered significant.

Results: 74 cows out of 7052 lactations (1.05%) were clinically diagnosed as suffering from pyelonephritis, Most were diagnosed at the beginning of the lactation (40% of all cases were diagnosed during the first 30 days; 60% during the first 90 days of the lactation).

44 urine samples were sent for bacterial analysis.. *C. renale* was isolated only from one sample (prevalence of 2.3%) in combination with *E.coli*. *E.coli* was the most prevalent bacteria in urine samples from cows diagnosed with pyelonephritis (N=30; 27 cases as a sole bacteria and 3 mixed infections; prevalence of 65.9% and 61.4% respectively). The second most prevalent bacteria was *Proteus mirabilis* cultured from 6 samples (13.6%) including one case of mixed infection with *E.coli*. In 8 cases no bacterial growth was demonstrated although bacteria, neutrophils and granular casts were demonstrated in cytology done in 3 cases.

Older cows are at risk for pyelonephritis in relation to 1st calf heifers (OR= 2.381 and OR = 2.891 for 2nd lactation and older cows respectively). Endometritis, Ketosis and twin calving were also identified as risk factors for pyelonephritis (OR =2.927, 1.693 and 2.206 respectively).

Catheterization before the diagnosis date of pyelonephritis was identified as a risk factor using the X² test (OR= 1.995, P=0.017) but when the effects of the factors Number of calves, CM and Ketosis were included catheterization before the diagnosis of pyelonephritis was not associated with UTI (P=0.133).

Conclusions: Pyelonephritis of the Israeli dairy cow is a disease associated with calving diseases (Twin calving, EM and Ketosis) and

higher parity. The most prevalent bacteria isolated from urine of cows with UTI are *E.coli*. Initial treatment of cows with pyelonephritis should be aimed at these bacteria, until bacterial isolation from the urine is obtained. Urethral catheterization after thought cleaning of the perineum with water and soap is not a risk factor for UTI in the dairy cow.

Internal Medicine

P03-003-127

A preliminary descriptive study and meta-analysis of patterns of bovine neoplasia in Ireland.

Máire C. McElroy¹ Rónan O'Neill² Gerald Collins³ Ann Sharpe¹ Colm Brady¹¹Pathology Division, Central Veterinary Research Laboratory, Backweston, Celbridge, ²Virology Division, Central Veterinary Research Laboratory, Celbridge, ³Veterinary Public Health Inspection Service, South, Ireland

Objectives: There are no published reviews of bovine neoplasia in Ireland, although a range of tumours are known to be present, including ocular squamous cell carcinoma (OSCC) which causes economic losses and has implications for animal welfare. Ireland is free from another economically important tumour, enzootic bovine leukosis (EBL), but sporadic bovine lymphomas (SBL) do occur. This preliminary report describes bovine tumours identified from a number of sources. A meta-analysis was performed on the different sets of data using available information on affected animals, to attempt to identify risk factors associated with certain tumours.

Materials and Methods: Three different sets of bovine tumour data were available. Dataset 1 comprised 48 tumours identified at post-mortem inspection in a number of Irish abattoirs from January 2014 to November 2015.

Dataset 2 comprised tumours identified from carcass referrals to the Veterinary Laboratory Service, from January 2010 to November 2015.

Histopathology was performed on formalin-fixed, paraffin-embedded tissue from all tumours in Datasets 1 and 2. Whenever lymphoma was diagnosed, either polymerase chain reaction (PCR) for enzootic bovine leukosis virus (EBLV) was performed directly on fresh-frozen tumour tissue, or an ELISA-based serological investigation was carried out in the herd of origin.

Dataset 3 was observational data on 279 ocular neoplasms (presumptive OSCC) identified at ante-mortem inspection in one abattoir between December 2009 and December 2013. Histopathological confirmation was not performed on the tumours from dataset 3.

County of birth, animal breed, age and gender were available from the Department of Agriculture, Food and the Marine's (DAFM) Animal Health Computer System (AHCS).

Results: Of the 48 tumours in Dataset 1, 28 (58%) were confirmed as OSCC, 6 (13%) as SBL, 5 (10%) as metastatic carcinoma/adenocarcinoma of unidentified origin, with melanomas, fibromas, and nerve sheath tumours also represented. All but five of the animals were female. Mean age at submission was 11.1 years. Commonest breeds were Friesian (Fr), MountBeliarde (Mo), Simmental (Si), Hereford (He), Limousin (Lm) and Other having frequencies 16, 5, 4, 4, 3 and 8 respectively.

In dataset 2, a total of 54 bovine tumours were detected at necropsy, thirty two (59%) of which were sporadic lymphoma.

In dataset 3, all animals were female. Commonest breeds were Fr, Mo, Si, He, Charolais (Ch) and Other having frequencies 136, 47, 38, 38, 7 and 13 respectively. Across all breeds the mean age at detection was 9.7 years with breeds Fr, Mo, Si, He and Ch having mean ages of 9.4, 9.3, 10.6, 9.7 and 11.4 years, respectively. The mean age at detection was significantly different ($p < 0.05$) between breeds Mo (the youngest) and He and Ch (the two oldest).

PCR and ELISA for lymphoma: all negative

Conclusions: This was a preliminary, descriptive study of bovine neoplasia rather than an accurate measure of prevalence.

OSCC was a relatively common tumour detected in abattoirs but not in submissions to the laboratory service, highlighting the value of abattoir surveillance for certain conditions.

There are indications of possible breed effects for OSCC (with Mo, He over-represented). This is probably related to lack of eyelid pigmentation but, in the case of Mo, may warrant further investigation.

Sporadic lymphomas were the most common tumours in submissions to the laboratory service.

Internal Medicine

P03-003-128

PLASMA AND PERITONEAL CONCENTRATIONS OF HMGB1 AND D-DIMER FROM CALVES WITH OR WITHOUT UMBILICAL HERNIA

Tatiane S. Polo¹, Gabriela Campos¹, Marilia Martins¹, Bianca Arnone¹, Luiz C. N. Mendes¹, Francisco L. F. Feitosa¹, Juliana Nunes¹, Silvia H. Perri², Juliana Peiro¹

¹Clinics, Surgery and Animal Reproduction, ²Animal and Health Production, FMVA-UNESP, Aracatuba, Brazil

Objectives: HMGB1 is a highly conserved protein across species, important in stimulating the release of several chemokines and pro-inflammatory cytokines by monocytes. The D-dimer is a degradation product linked to fibrin from fibrinolysis, strongly associated with hypercoagulability activity. The objectives were to determine plasma and peritoneal concentrations of the HMGB1 and D-dimer proteins in calves with congenital umbilical hernia (CUH) before and after hernia repair, determining which compartment these proteins reflect better and faster inflammatory changes.

Materials and Methods: Were collected peritoneal fluid (PF) and venous blood of 20 Holstein calves with umbilical hernia ($n = 10$) and healthy ($n = 10$) on day 0 (before hernia repair), 1, 3, 5, 7 and 15 days. The HMGB1 levels were determined by sandwich ELISA (ST 51011 kit, IBL International, Toronto, ON, Canada.) as described by Brown et al. (2009), and D-dimer determined using an immunoassay kit (Nycocard Reader D-dimer, Axis-Shield, Shanghai, China) as described by Wittek et al. (2010), comparing the time between samples and between groups.

Results: Congenital umbilical hernia caused elevation of HMGB1 concentrations both in plasma and in the peritoneal fluid (PF) when compared to controls, whereas D-dimer levels were increased in plasma. HMGB1 is an important pro-inflammatory cytokine in various diseases. Because no animal showed ischemia of the herniated portion, no alteration of D-dimer levels were observed locally. After hernia repair, the concentration of HMGB1 decreased in the first five days in plasma and PF, and increased at 15 days after surgery in PF. This cytokine may be as early or late trigger modulators of inflammation depending on the

stimulus. D-dimer remained elevated in the hernia group up to 7 days in plasma and up to 3 days in PF compared to the controls. These findings correspond to a modest increase in systemic and local fibrinolytic activity after repairing a hernia due to the degradation of fibrin.

Conclusions: Increases of HMGB1 and D-dimer levels suggest that the local and systemic acute inflammatory response were caused by the presence of the umbilical hernia in calves. Hernia presence increased D-dimer concentrations previously to HMGB1. Finally, HMGB1 and D-dimer can be used in the evaluation of local and systemic inflammatory response in calves with umbilical hernia.

Internal Medicine

P03-003-129

Use Of Alivecor Heart Monitor For Heart Rate And Rhythm Evaluation In Water Buffalo Calves (Bubalis Bubalis)

Joe Smith¹, Jessica Ward², Tara Urbano³, Mikaela Mueller⁴

¹Veterinary Diagnostic and Production Animal Medicine, ²Veterinary Clinical Sciences, Iowa State University College of Veterinary Medicine, Ames, ³School of Veterinary Medicine, University of California-Davis, Davis, ⁴Cardiology, Blue Pearl Veterinary Partners, Seattle and Renton, United States

Objectives: Objectives of this study were to evaluate the use of a smartphone-based electrocardiogram (ECG) device (AliveCorECG™) in dairy water buffalo calves for the determination of heart rate and rhythm. Additionally, the quality of ECG from the AliveCor device was compared to a standard 6-lead ECG.

We hypothesized that the AliveCor device could be used to obtain an accurate heart rate and rhythm in water buffalo calves in a field setting.

Materials and Methods: Six healthy neonatal water buffalo calves had simultaneous AliveCor and standard 6-lead ECGs performed. Calves were haltered and recordings were taken in a standing position. The AliveCor ECG was recorded with the device placed over the left cardiac apex. Paper speeds was 25 mm/sec and amplitude was 10 mm/mV. All ECGs were evaluated unpaired and independently by a data-blinded veterinary cardiologist. The average heart rate was determined based on 6 seconds of ECG recording, rhythm diagnosis was recorded for each tracing, and each ECG was given a quality score. The findings were then reviewed to determine if the AliveCor device was comparable to the 6 lead ECG for rate and rhythm diagnosis. A paired t-test was used to assess for significant differences between each calf's average heart rate determined by the AliveCor device and the 6-lead ECG, and a Mann-Whitney test was used to compare the quality scores between the two readings for each calf.

Results: All animals were healthy and had no murmurs on pre-recording physical examination.

There was no significant difference between average heart rates obtained between AliveCor recordings when compared to those from the 6 lead ECG ($P = 0.174$). A normal sinus rhythm was recorded for all 12 recordings.

The AliveCor recordings of 4/6 calves most closely resembled lead aVR, while recordings of 2/6 calves more closely resembled lead II.

No significant difference was observed between standard and AliveCor quality scores ($P = 0.6250$).

Conclusions: We conclude that the AliveCor device allows for accurate heart rate determination and diagnosis of a normal sinus rhythm in neonatal dairy water buffalo calves, when taken in a standing position from the left heart base in a field setting.

Insulinoma In A 5-Year-Old Dexter Cow With Persistent Hypoglycemia

Cagri Binici^{1,*}Stephanie Plog²Olivia Kershaw²Marion Schmicke³Johannes H. van der Kolk⁴Kerstin E. Müller¹

¹Department of Veterinary Medicine, Freie Universität, Clinic for Ruminants and Swine, ²Department of Veterinary Medicine, Freie Universität, Institute of Veterinary Pathology, Berlin, ³University of Veterinary Medicine, Hanover, Foundation, Clinic for Cattle, Hanover, Germany, ⁴Department of Clinical Veterinary Medicine, Swiss Institute for Equine Medicine (ISME), Bern, Switzerland

Objectives: A Dexter cow aged five years in the fifth month of pregnancy was referred to the Clinic for Ruminants and Swine, Department of Veterinary Medicine, Freie Universität Berlin, Germany, by a local practitioner due to general weakness and ataxia that did not respond to treatment.

Materials and Methods: At admission, the cow was clinically examined according to Rosenberger [1] and blood samples were obtained for laboratory testing. An intravenous glucose tolerance test was performed. While plasma glucose concentrations were determined in the laboratory of the clinic, serum samples for determination of insulin were sent to the Endocrinology Laboratory, Clinic for Cattle, Tierärztliche Hochschule Hannover. A radioimmunoassay was applied for the quantification of serum insulin concentrations in cattle¹.

Results: The general condition and demeanor of the cow were severely impaired. The cow demonstrated an uncertain stance characterized by inability to properly support the body weight by its legs. When walking, the animal showed ataxic movements and a hypermetric gait. Besides the symptoms described above, the neurological examination demonstrated bilateral mydriasis as well as delayed pupillary reflexes (direct/indirect).

Results of blood analysis revealed a persistent hypoglycemia (glucose levels: 1.4 – 1.9 mmol/l). The Dexter cow, however, did not respond with ketone body production or excessive lipomobilization in the face of hypoglycemia. Therefore, an insulin-secreting tumor was suspected and an intravenous glucose tolerance test (IVGTT) confirmed the latter assumption.

Conclusions: All treatment attempts including providing glucogenic nutrients and precursors (glycerol and propylene glycol) failed and the condition of the cow deteriorated during hospitalization. Due to the clinical condition and the unfavourable prognosis, euthanasia was elected and the animal was sent for necropsy to the Institute of Veterinary Pathology, Faculty of Veterinary Medicine (Freie Universität Berlin). At necropsy, multifocal, highly infiltrative, white-grey nodules were present in the pancreas. An immunohistochemical examination confirmed the clinical diagnosis of insulin-producing islet cell tumor in the pancreas.

Bacterial Communities Associated With Healthy Abomasal Mucosa And Ulcers In Cattle

Alexandra Hund¹Monika Dzieciol²on behalf of Institute for Milk Hygiene, Milk Technology and Food ScienceStephan Schmitz-Esser¹on behalf of Institute for Milk Hygiene, Milk Technology and Food ScienceThomas Wittek^{1,*}on behalf of University Clinic for Ruminants

¹Department for Farm Animals and Veterinary Public Health, University of Veterinary Medicine Vienna, ²Department for Farm Animals and Veterinary Public Health, University of, Vienna, Austria

Objectives: The present study was performed to characterize bacterial communities of slaughter cows, bulls and calves. The communities of healthy and ulcerated mucosa were compared to potentially identify pathogens contributing to the lesions.

Materials and Methods: Abomasal mucosa samples were taken after slaughter from three different groups: fattening bulls, cows, and calves. Within each group, the ulcerated abomasal mucosa of affected animals, unaffected mucosa of these same animals with ulcers, and abomasal mucosa of healthy animals were sampled. In total, 63 samples from 42 animals were analyzed. DNA of the samples was extracted and the V1–V2 region of bacterial 16S rRNA genes was amplified and pyrosequencing was performed. The sequences were analyzed using the software mothur and classified into operational taxonomic units (OTUs). Furthermore, diversity indices and Yue & Clayton Theta similarity coefficients were calculated. The similarity between bacterial communities was analysed and it was determined which OTUs showed a statistically significant different abundance between the groups.

Results: The bacterial communities associated with abomasal ulcers of slaughter cows, bulls, and calves in Austria were described using 16S rRNA gene pyrosequencing. Sequences were clustered into 10,459 operational taxonomic units (OTUs), affiliating to 28 phyla with Proteobacteria, Firmicutes, Bacteroidetes and Tenericutes dominating (96.4% of all reads). The most abundant genera belonged to Helicobacter, Acetobacter, Lactobacillus, and novel Mycoplasma-like phylotypes. Significant differences between the microbial communities of calves compared to cows and bulls could be observed. However, only few statistically significant differences in the abundances of certain OTUs between healthy and ulcerated abomasal mucosa were found.

In all groups there was a high diversity of bacteria attached to the abomasal mucosa. When comparing ulcerated mucosa, unaffected tissue of the animals with ulcerated mucosa and mucosa from healthy animals no statistically significant differences of species richness and diversity estimators were found. Only significant differences for the different animal groups (cows, bulls, calves) and also when comparing adult animals (cows and bulls) and calves were found.

Conclusions: The present study provides the first deep insights into the bacterial microbiota of healthy and ulcerated abomasal mucosa in cattle. A high diversity of bacteria attached to the abomasal mucosa in bulls, cows and calves was found. Distinct differences in the bacterial communities between calves on one hand and cows and bulls on the other hand have been identified. A relationship between microbiota and abomasal ulcers could not be established. However, since all ulcers in cattle of the study were least severe type of ulcers the question remains if there could be an influence of certain bacteria on the formation of more severe lesions.

Echocardiographic assessment of left ventricular systolic function in calves with naturally occurring severe sepsis and septic shock

Amir Naseri ¹, Ismail Sen ¹, Kursad Turgut ¹, Hasan Guzelbektes ²

¹Selcuk University, Faculty of Veterinary Medicine, Konya, Turkey,

²Kyrgyz-Turk Manas University, Faculty of Veterinary Medicine, Bishkek, Kyrgyztan

Objectives: Until now, there is no literature information about longitudinal transthoracic echocardiographic (TTE) evaluation of cardiovascular insufficiency and changes in left ventricular systolic function in calves with naturally occurring severe sepsis and septic shock and how systolic function is affected by fluid therapy in calves. For this reason, the aim of the study was (1) to evaluate changes in left ventricular systolic function by TTE before and after treatment and, (2) to evaluate the echocardiographic changes in LV systolic function according to the treatment options.

Materials and Methods: Ten hypotensive calves, 0-4 weekly, with complete laboratory and clinical data necessary for systemic inflammatory response syndrome and multiple organ dysfunction syndrome classification (experimental group), and 5 healthy calves, 0-4 weekly, (control group) were used as materials. TTE examinations were performed before the treatment, after the first bolus of fluid resuscitation and on the first, second and third days of the treatment. To assess LV systolic function, end diastolic volume index (EDVI), end systolic volume index (ESVI), ejection fraction (EF%), fractional shortening (FS%), stroke volume (SV), cardiac index (CI), pre-ejection period/ejection time (PEP/ET) were determined in the experimental group of calves. TTE examinations for the determination of the same systolic function indices were performed once on the control group of calves. Non-invasive arterial blood pressures [Systolic blood pressure (SBP) and mean arterial pressure (MAP)] were also monitored during the hospitalization. Fluid therapy [boluses containing hydroxyethyl starch (10 ml/kg/h) and 0.9 % NaCl (65ml/kg/h)] was administrated to the experimental group of calves during the hospitalization. The goal in the fluid therapy of the experimental group of calves was to obtain the followings; systolic blood pressure >90 mm/Hg and/or mean arterial pressure >65 mmHg, normalisation of clinical and cardiological findings, and lactate levels <4 mmol/L.

Results: SBP and MAP (71.9±6.53 mmHg and 51.7±3.96 mmHg, respectively) were low at the admission and increased after the first bolus of fluid resuscitation (123±5.76 mmHg and 88.1±3.81 mmHg, respectively) (p<0.05) and remained normal during the hospitalization (p>0.05). EDVI and ESVI (15.3±3.58 ml/m² and 6±1.91 ml/m², respectively) increased after the first bolus of fluid resuscitation (44.8±4.44 ml/m², 20±2.85 ml/m², respectively) (p<0.05) and did not change during the hospitalization (p>0.05). SV and CI (9.2±1.48 ml and 1150±247 ml/min/m², respectively) increased after the first bolus of fluid resuscitation (24.9±2.52 ml and 3165±45 ml/min/m², respectively) (p<0.05) and did not change during the hospitalization (p>0.05). The EF, FS and PEP/ET did not different during the study (p>0.05).

Conclusions: The result of the study showed that fluid resuscitation in calves with severe sepsis and septic shock improved the preload and the afterload and TTE was a very useful tool in the monitorization of fluid therapy and it's effect on cardiovascular system.

Effect of sedation on the intrapulmonary position of a bronchoalveolar lavage catheter in calves

Laura Van Driessche ¹, Bonnie R. Valgaeren ¹, Peter De Schutter ², Linde Gille ¹, Filip Boyen ³, Richard Ducatelle ³, Piet Deprez ¹, Bart Pardon ¹

¹Department of Internal Medicine and Clinical Biology of Large Animals, Faculty of Veterinary Medicine/ Ghent University, Ghent, Belgium, ²Veterinary Clinic Stenay Mouzon, Stenay-Mouzon, France, ³Department of Pathology, Bacteriology and Avian Diseases, Faculty of Veterinary Medicine/ Ghent University, Ghent, Belgium

Objectives: The vast majority of bacterial pneumonias in calves are situated in the cranioventral lung lobes. Non-endoscopic sampling with a broncho-alveolar lavage (BAL) catheter is a practical method to sample larger groups of animals in an economic way. For practical and welfare reasons sedation of calves during the BAL procedure might be warranted. To date it is unknown which lung lobes are sampled by this non-endoscopic procedure and whether this is influenced by sedation. Therefore, the objective of this study was to determine the effect of the most commonly used sedation in cattle (xylazine) on intrapulmonary position of a BAL catheter.

Materials and Methods: A randomised clinical trial was performed on 18 male Holstein Friesian calves (mean age=8.5 months +- standard deviation (SD)=3.5 months). Calves were randomised over the two treatments, being sedation with a single dose of 0.1 mg/kg body weight xylazine intramuscularly (Xyl-M 2%, VMD, Arendonk, Belgium) and a placebo (2 mL of saline solution). In each calf a BAL was performed. The intrapulmonary position of the BAL catheter was determined by endoscopy and contrast-radiography with barium. In the control group this positioning was validated by euthanasia with the catheter in place and post-mortem examination. Histological examination was done for 3 calves at different sites of the respiratory tract (nasopharynx, trachea, large bronchi and the different lobi). For statistical analysis the intrapulmonary position of the catheter was characterised with binary values (cranial vs. caudal; left vs. right and dorsal vs. ventral) and logistic regression was used.

Results: A BAL catheter was introduced in 18 calves, of which 11 were sedated and 7 served as controls. In the control the probability of sampling the different lung parts is equally distributed in the control animals: 14.3% dorsocranial, 28.6% dorsocaudal, 28.6% ventrocranial and 28.6% ventrocaudal. In contrast, in sedated animals systematically the dorsocaudal lung part was sampled (100% vs. 28.6%). Sedation had a significant effect on the dorsal vs. ventral (P<0.05) and cranial vs. caudal positioning (P<0.05), but not on left-right distribution (P= 0.49). Histology revealed acute inflammation of the proximal nasal cavity, proximal trachea and distal trachea.

Conclusions: In conclusion, a BAL-catheter, introduced without endoscopic guidance, samples a random lung lobe in unsedated animals, and not systematically the most affected cranial lobes. When sedation is applied, the dorsocaudal lung lobes, which are less frequently affected, are systematically sampled. To what extend this difference in intrapulmonary position of the BAL-catheter affects the likelihood to isolate the causative bacteria remains to be determined.

Internal Medicine

P03-003-134

Early Signs Of Diarrhea In Neonatal Calves In The First Fifteen DaysOnur Topal¹ Hasan Batmaz^{1*}¹Internal Medicine, University of Uludag, Faculty of Veterinary Medicine, Nilüfer-Bursa, Turkey

Objectives: Health of neonatal calves is very important. Therefore, preventive measures and early treatment of diseases are essential to prevent economic losses. The objective of the study was to investigate daily clinical signs in the first 15 days in neonatal calves whether clinical manifestations of the diarrhea.

Materials and Methods: Clinical investigations were performed in 52 Holstein calves. Calves were examined on each day in the first 15 days after birth. In these examination, posture, enophthalmus, skin elasticity, capillary filling time (CFT), appearance of eyes, lacrimation, colour of conjunctiva and mucosa, appearance of muzzle, temperature of muzzle and tip of nose, nasal discharge, sucking reflex, palpebral reflex, temperature of mouth, movements of ears, position of ears, temperature of ears, heart frequency, auscultation of heart, respiration frequency, auscultation of lung, cough, rectal temperature, volume, consistency, smell and colour of feces, lethargy score of the calves were evaluated totally 27 parameters on each day. All parameters were evaluated as normal (score 1), questionable healthy (score 2) and disease sign (score 3). It was observed that 18 calves were healthy and 34 calves had undifferentiated diarrhea.

Results: A day before these 34 calves suffered diarrhea, most observed score 2 and score 3 parameters, respectively, were as follows: Increased heart frequency (24, 70.5%), softening of consistency and bad smell of feces (16, 47.5%), coldness of ears (14, 41.17%), yellow-gray colour feces (13, 38.23%), change in feces volume (11, 32.25%), CFT 2-3 sn (10, 29.41%), change in conjunctiva and mucosa colour, and lacrimation (9, 26.47%), abnormal posture (low shoulders, kiphotic and upturned tail), enophthalmus and lethargy score 2 (8, 23.52%), skin losses its elasticity 2-4 sn and nasal discharge (7, 20.58%), abnormal rectal temperature, coldness muzzle and tip of nose, and weakening of sucking reflex (6, 17.64%). Average birth weights of calves suffered from diarrhea was 39.32 kg, others was 40.19 kg. Average weight on 15th day was 41.47 kg and 43.75, respectively. Although those calves not suffered from diarrhea gained approximately 2 more kg than the ones with diarrhea, it wasn't statistically significant.

The bad smell and yellow-gray color of feces, coldness of ears, prolonged of CFT, change of conjunctiva and mucosa colour, lacrimation, posture, enophthalmus and lethargy were observed as early symptoms occurs before diarrhea in neonatal calves. Approximately %70 of calves had increased heart frequency. However this might be result of stimulation of the calves. Diarrhea occurs before softening to the consistency of the feces are expected to be finding.

Conclusions: As a result, the first 15 days of neonatal calves the bad smell and yellow-gray color of feces, coldness of ears prolonged of CFT, change of conjunctiva and mucosa colour, lacrimation, posture, enophthalmus and lethargy, it can be argued that as early signs occurs before diarrhea.

P03-003-135

Outbreak of hiperacute highly lethal faringeal flegmon in a Limousin herd originated by a new Pasteurella multocida, type ST 63Juan V González-Martín^{1,2*} Raquel Patrón¹ Juan A. Díaz de Tuesta³ Natividad Pérez-Villalobos¹ Cristiana Justo¹ Ana I. Vela²¹Trialvet SL, Cabanillas de la Sierra, ²Universidad Complutense, ³Laboratorio Regional de Sanidad Animal, Madrid, Spain

Objectives: Description of an outbreak of pharyngeal flegmon with very high mortality, by Pasteurella multocida, in an extensive herd of 40 Limousin cows, 1 bull, 10 heifers and 34 calves, in the province of Toledo (central Spain) from 11th to 23th April 2015 and typing of bacteria.

Materials and Methods: An epidemiological study was conducted. Necropsies were performed on 2 calves, 2 heifers and 1 cow. Samples were taken for standard histopathological and microbiological study. Presumptive identification of isolate as P. multocida was performed by Gram staining, oxidase and catalase test and the commercial identification system API 20NE test strips (bioMérieux), according to the manufacturer's instructions. Capsular types of the isolate (A, B, D, E, and F) were determined using multiplex PCR (Townsend et al., 2001). The gene toxA, which encodes the dermonecrotic toxin of P. multocida, was determined as previously described (Lichtensteiger et al., 1996). Multi locus sequence typing (MLST) was carried out as previously described (Davies et al., 2003). MLST alleles and the resulting sequence type (STs) were assigned through submission of the respective data to the multihost P. multocida MLST database (http://pubmlst.org/pmultocida_multihost/). The antimicrobial susceptibility was tested by the diffusion method as described by the Clinical Laboratory Standards Institute (CLSI, 2015). The animals were treated with oxytetracycline LA im and vaccinated with a poliostridial vaccine.

Results: Within 13 days of the outbreak 4 cows (10%), 2 heifers (20%) and 9 calves (26.5%) died, with a course of 24 hours. Only 1 cow showed throat inflammation at mass treatment time survived without sequels, all the others affected animals were found dead or died immediately after displaying severe respiratory distress without depression. The outbreak ceased when all animals were prophylactically treated, without cases out the dates indicated. All necropsied animals and the remainder observed by the owner presented exclusively inflammation with extensive oedema in the throat area other than a heifer presented the problem in a limb and died in three days. Only flegmon was found in autopsies and the cause of death was asphyxiation. Purulent laryngitis was diagnosed in the pathological study of 3 sampled animals. Gram-negative rod-shaped organisms about 1 µ and neutrophil infiltration, oedema, hemorrhage, vasculitis, thrombosis and microabscesses was observed in all tissues around the pharynx: salivary gland, connective tissue, muscle and retropharyngeal lymph. P. multocida was isolated in pure culture in the retropharyngeal lymph of the only 2 animals sampled, and was characterized in the capsular type B. The dermonecrotic toxin gene toxA was not detected. With the multi host P. multocida MLST database, the isolate was assigned to the new sequence type ST63. In the antibiogram the isolate was susceptible to tetracycline, florfenicol, ampicillin, gentamicin, ceftiofur, ST and enrofloxacin; resistant to penicillin and clindamycin; and intermediate to erythromycin, and amikacin.

Conclusions: P. multocida is a Gram-negative bacterium. Capsular type A is a common bovine nasopharyngeal commensal and a pathogen implicated in BRD and in lesser extent mastitis and vaginal discharge. Types B and E are implicated in hemorrhagic septicemia (HS) not confirmed in Western Europe. And type F in head oedema. None of the necropsied animals were septicemic and not showed multisystemic petechial haemorrhages or depression characteristics of HS. A hard and

spiny hay offered just before the outbreak started could have traumatized the pharynx and being the potential gateway of this novel clinical picture originated by a new *P. multocida* type ST63.

Internal Medicine

Intravenous electrolyte solution with high concentration of sodium lactate can correct metabolic acidosis in goats with acute rumen lactic acidosis

Priscilla F. V. Pereira¹Fernanda T. N. A. M. Romão²Juliana L. Massitel³Stefany L. O. Camilo³Thiago Marquez³Karina K. M. D. C. Flaiban⁴Júlio A. N. Lisboa^{1,*}

¹Departamento de Clínicas Veterinárias, Universidade Estadual de Londrina, Londrina, ²Hospital Veterinário, FAEF, Garça, ³Universidade Estadual de Londrina, Londrina, Brazil, ⁴Departamento de Medicina Veterinária Preventiva, Universidade Estadual de Londrina, Londrina, Brazil

Objectives: The aim of this work was to test the efficacy of an intravenous electrolyte solution formulated with high concentration of sodium lactate for the correction of metabolic acidosis in goats with induced acute rumen lactic acidosis (ARLA).

Materials and Methods: Six healthy saanen goats weighing 40kg body weight (BW) were induced to acute rumen lactic acidosis with 15g of sucrose per body kg. Each goat was submitted to induction twice, with at least 30 days of intervals. The goats were allotted to two groups where treatment consisted in continuous intravenous infusion of 4L (25mL/Kg/h) of an electrolyte solution containing 84mEq/L of sodium lactate (L84) or 84mEq/L of sodium bicarbonate (B84). Blood and urine samples were taken at times -18h (before the induction), 0h (start of infusion), 2h (middle of infusion), 4h (end of infusion), 6h, 12h and 24h after the beginning of infusion. Blood gases, pH, electrolytes and L-lactate were measured. The anion gap (AG) and strong ion difference (SID) were calculated. The data were analyzed by two way repeated measures ANOVA.

Results: Clinical signs and ruminal fluid alterations compatible with ARLA were observed in all animals 18 hours after the induction. The metabolic acidosis due to ARLA was moderate with a reduced blood pH (L84 group: 7,275±0,08; B84 group: 7,232±0,08), decreased HCO₃⁻ (L84 group: 16,03±2,27mmol/L; B84 group:14,40±2,27mmol/L) and BE (L84 group:-11,56±3,23mmol/L; B84 group:-13,33±3,92mmol/L). Goats that received L84 presented the following values at the end of the infusion: pH=7,471±0,07; HCO₃⁻= 26,88±2,30mmol/L; pCO₂=36,58±5,24mmHg; BE=3,71±3,19mmol/L; Na⁺=142,88±2,65mmol/L; K⁺=3,00±0,93mmol/L; Cl⁻= 102,96±3,74mmol/L; SID= 42,92±1,49mmol/L and AG=16,13±1,76mmol/L. The values in B84 group were similar to these. Both treatments were able to correct the metabolic acidosis, dehydration and electrolytes imbalances presented without differences between them (p>0,05). The plasmatic L-lactate concentration increased during the infusion of L84 solution from 2,03±0,69mmol/L in the beginning to 9,35±1,28mmol/L at the end. However, returned to low levels six hours later (1,0±0,67mmol/L). The L-lactate fractional clearance increased only in the end of the L84 infusion, indicating that L-lactate was metabolized and the excess was excreted. All goats were completely recovered 3 to 4 days later.

Conclusions: The novel electrolyte solution containing high concentration of sodium lactate (L84) was effective in the treatment of metabolic acidosis induced by ARLA in goats, as an alternative to

bicarbonate solutions. Infusions of large volumes are safe and no side effects were observed.

Internal Medicine

P03-003-138

The effect of current standard therapy on clinic, hematologic and biochemical parameters in calves with severe sepsis and septic shock

Ismail Sen^{1,*}Kursad Turgut¹Hasan Guzelbektes²Amir Naseri¹

¹Selcuk University, Faculty of Veterinary Medicine, Konya, Turkey, ²Kyrgyz-Turk Manas University, Faculty of Veterinary Medicine, Bishkek, Kyrgyztan

Objectives: Severe sepsis and septic shock that cause high mortality rate are commonly seen in both human and veterinary medicine. Until now, unfortunately, there is no longitudinal clinical research concerning with treatment of calves with naturally occurring severe sepsis and septic shock.

The aim of this study was to evaluate the effectivity of current standard therapy (oxygen, antibiotic and fluid administration) on clinic, hematologic and biochemical parameters during the treatment of calves with naturally occurring severe sepsis and septic shock.

Materials and Methods: Ten hypotensive calves, 0-4 weekly, with complete laboratory and clinical data necessary for systemic inflammatory response syndrome and multiple organ dysfunction syndrome classification (experimental group), and 5 healthy calves, 0-4 weekly, (control group) were used as materials. Blood samples for hematology, blood gas and serum biochemistry were collected once from the control calves. However, blood samples were collected before treatment and after treatment as intervals from vena jugularis in the experimental group calves. As treatment, oxygen, antibiotic (ceftiofur, 2.2 mg/kg) and fluid were administrated. The experimental calves were monitorized by ECG during treatment.

Results: According to the history taken from the owners, the calves had been affected about 24 hours and over. Calves had no suckling reflex, mostly lateral in position and mental depression. Clinical findings of calves did not improve after the treatment at 72 hours. There was no statistically difference in clinical findings between baseline and after treatment. All the calves had severe metabolic acidosis (pH<7.2) and > 8 dehydration degree at admission. Each calf received intravenous colloid (HES 10 ml/kg/h)+crystalloid (0,09%NaCl 65ml/kg/h) solution combination during the treatment. Venous blood pH was increased (pH>7.3), but lactate levels (<2.3 mmol/L) was decreased after the treatment at 6 h. Most of the calves had high whole blood count (WBC) on admission. However, WBC was decreased after treatment at 72 hours, but WBC was still high compared to control group. Serum creatinine, AST, ALP and GGT levels of the experimental group calves were still high after the treatment at 72h compared to the values before treatment (p<0.05).

Conclusions: Current standard therapy in calves with naturally occurring severe sepsis and septic shock improved acid-base parameters and lactate levels, but not the clinical findings. It was considered that majority of the calves might have died from multiple organ dysfunction syndrome due to increased serum enzyme levels. Therefore, it can be concluded that duration of disease in calf with severe sepsis and septic shock is the most important factor for prognosis.

Internal Medicine

P03-003-139

Gas Gangrene caused by *Clostridium Novyi* in a high-end genetic Holstein embryo donor during a series of superovulation injections

Cathy Furness¹ Adam Haight² Goncalo Silva³ Henry Staempfli^{3*}

¹Lead Veterinarian Planning and Preparedness, Ontario Ministry of Agriculture, Food and Rural Affairs, Guelph N1G2W1, ²Kirkton Veterinary Clinic, Kirkton N0K 1K0 Ontario, ³Clinical Studies, Ontario Veterinary College University of Guelph, Guelph N1G2W1, Canada

Objectives: A clinical case of gas gangrene caused by *Clostridium Novyi* is presented following multiple injections using the Follotropin V protocol. This was a first calf HF cow that had developed a very firm swelling of the right gluteal region 8 hours post administration of 4th im injection of FSH with sterile needles. The cow was moderately painful and toe-touching lame of the right hind. She was 160 days in milk and ranked in the 99% percentile for milk production and milk fat/protein and was producing 45-50 kg milk/day. Using this case best treatment options and prevention for gas gangrene in valuable Bovine embryo donors is discussed.

Materials and Methods: The cow was from a 700 head free stall dairy herd, milking 3 times daily with TMR feeding. She was subjected to a embryo superovulation procedure using the Follotropin-V protocol. Vaccination of the herd is a 10 way modified live vaccine (BoviShield Gold FP5 + L5) twice pre-breeding and 21-50 days pp with no clostridial vaccines. The cow was alert and responsive and swelling extended from the tuber coxae to ischiatic tuberosity and lumbar spine through to the biceps femoris with no creptius present. She had received Pen IM once prior to presentation. Vital parameters were normal. Rumen, Udder and CMT, as well as GI tract were normal. Ultrasonography of right gluteal region revealed fluid pouches with no gas but tissue edema. A CBC had neutrophil toxicity while the serum biochemistry showed moderate elevations in AST (248 IU/L) and CK (1768 IU/L and no other abnormalities. Gram stain of a fine needle aspirate of the right gluteal muscles yielded gram positive bacilli and degenerate neutrophils; culture identified +++ *Clostridium novyi*. To relieve tissue pressure and to enable exposure to air a total of 6 vertical fasciotomy incisions of affected gluteal and biceps femoris region were placed along both skin and fascial planes. IV ringers with antibiotic (Na-Pen 44000 IU/kg q6h) and analgesic medication (Flunixin Meglumine 1mg/Kg q12h) were started. Local rinsing with H₂O₂ solution and local hydrotherapy were performed q6h for 30 minutes and she was walked for good blood circulation in affected tissues.

Results: Within hours following fasciotomy, the right gluteal swelling began to decrease; the lameness improved markedly however there was minimal improvement of general comfort level. On day two of hospitalization an epidural catheter was placed and a morphin/detomidine/saline combination was intraepidurally given every 6 h as adjunct analgesia for two days.

The fasciotomy sites were debrided on a daily basis and rinsed with H₂O₂. Warm/cold hydrotherapy and exercise was increased. Over the following three days the cow remained stable but still extremely painful over the affected muscle area. Based on recent information on day three systemic treatment with oxytetracycline (20mg/kg diluted in 1L saline) q24h was added. Milk production had dropped to 0L but gradually returned to >30 L. Medication was discontinued on day 8 after admission. The cow was sent home with the recommendation to vaccinate cows entering the embryo superovulation program with a multiway clostridial vaccine. Over a period of the next two years the cow was kept as an embryo donor. No further cases of gas gangrene were observed in this dairy herd over this period.

Conclusions: Take home message is to re introduce a multiway clostridial vaccine in dairy cows used for embryo superovulation procedures. Dormant spores in healthy musculature of such cows could have preexisted. Presence of dormant spores of a multitude of clostridial species was confirmed in horses in 20% of sterily obtained muscle samples in freshly euthanized horses. Unpublished data from our lab showed that 5% of such muscle samples in cattle were positive for organisms such as *C. perfringens* and *C. difficile* among others. Early treatment of clostridial myonecrosis with tissue fasciotomy might be the best way to have successful outcome of such cases.

Blood Gas Analysis In Relation To Clinical Symptoms From Diarrhea Calves

Sunghwan Lee^{1*} Hyeokho Kwon¹ Doo Kim¹ Sangtae Shin²

¹College of Veterinary Medicine, Kangwon National University, Chuncheon, ²College of Veterinary Medicine, Chungnam National University, Daejeon, Korea, Republic Of

Objectives: Calf diarrhea is a major cause of economic loss to cattle industry worldwide. The aims of this study were to determine blood gas and biochemical values and to analysis blood values in relation to clinical symptoms from diarrhea calves.

Materials and Methods: From July to September in 2014, a total of 68 diarrheal calves under 3 months old (both Korean native calf and Holstein) were investigated. History taking and physical examination were conducted. The depression score of physical activity was classified as bright, dull, dummy, and coma. The venous blood sample was collected from jugular vein and immediately analyzed by iSTAT 1 portable clinical analyzer (Abbott Point of Care Inc., Abbott Park, IL 60064, USA) with the EC8⁺ cartridge. The relationship between the clinical symptoms and blood values was analyzed by Jonckheere Terpstra trend test.

Results: In 68 diarrheal calves, 8, 22, 34, and 4 calves belonged to bright, dull, dummy, and coma, respectively. The values for pH, carbon dioxide partial pressure, bicarbonate, base excess, and glucose were decreased according to deterioration of physical activity status ($p < 0.05$). And the values for anion gap, hemoglobin, hematocrit, and potassium, BUN were increased getting with deterioration of physical activity status ($p < 0.05$). The values of hematocrit ($p = 0.006$), hemoglobin ($p = 0.007$), and total carbon dioxide ($p = 0.002$) were good prognosis indicator. The value of BUN according to physical activity status was significantly increased getting with deterioration of physical activity status ($p < 0.0001$). The difference in concentration of sodium and chloride among each physical status groups were not statistically significant (p value > 0.05).

Conclusions: This study provides the information on the blood gas status of diarrhea calves in summer season and guide practitioners through a decision-making process which will minimized the negative impact of diarrhea on individual patients as an accurate diagnosis and ultimately its economic impact on the cattle industry as a whole.

Arterial And Venous Blood Gas, Electrolytes, Biochemical And Hematological Values In Healthy Korean Native Calves

Sunghwan Lee ¹;Seunghoon Ok ¹Doo Kim ¹

¹College of Veterinary Medicine, Kangwon National University, Chuncheon, Korea, Republic Of

Objectives: The normal reference data on blood gas analysis of Korean native cattle has not been examined yet. The objective of this study was to investigate arterial and venous blood gas figures of Korean native calves. We studied 62 calves under 3 weeks old to find reference data of Korean native calves. Furthermore, we compared arterial blood gas data with those of venous blood.

Materials and Methods: The 62 healthy Korean native calves under 3 weeks old were examined. The arterial blood was collected from caudal auricular artery (Fisher and others 1980) and the venous blood from jugular vein. The blood samples were analysed immediately using a portable blood gas analyser (EPOC, Woody Equipment Company Ltd, UK). The pH, pO₂, pCO₂, cHCO₃⁻, BE, cSO₂, Na⁺, Ca²⁺, Cl⁻, aniongap potassium(AgapK), Hct, cHgb, glutamine, lactate and creatinine were determined. Statistic analysis was conducted with SAS.

Results: The mean of arterial and venous pH, BE, cHCO₃⁻ of 62 Korean native calves were 7.44±0.04 vs 7.41±0.04, 2.3±3.3 vs 4.3±2.9mEq/L and 26.4±2.8 vs 29.0±2.5mmol/L, respectively. Glucose (r=0.927) had the strongest correlations between arterial and venous values. The correlation between the values of the arterial and the venous blood was strong in creatinine (r=0.925), lactate (r=0.815), Ca²⁺ (r=0.806), Hct (r=0.799), Na⁺ (r=0.790), cHgb (r=0.786), base excess (r=0.749), pH (r=0.710), HCO₃⁻ (r=0.710), and cTCO₂ (0.663).

Conclusions: This study obtained the normal reference data of arterial and venous blood gas analysis of Korean native calves under 3 weeks old. The arterial and venous pH, BE, and cHCO₃⁻ values were significantly correlated, respectively.

Physico-Chemical Approach To Urinary Acid-Base Alterations In Sheep With Induced Metabolic Hypochloremic Alkalosis

David Martinez ¹;Olimpo Oliver ²

¹Physiology, Faculty of Medicine, ²Animal Health, Faculty of Veterinary Medicine and Zootechny, National University of Colombia, Bogota DC, Colombia

Objectives: The objective of this study was to determine the relationship of the independent variable strong ion difference (SID) and urinary pH in sheep with induced hypochloremic metabolic alkalosis, using the net acid secretion to calculate the SID in an experimental model of massive loss of abomasal fluid through a duodenal cannula.

Materials and Methods: Seven ovine subjects were surgically implanted with a duodenal cannula. They had a period of recovery from surgery that lasted 14 days. Once, the experimental subjects were determined to be

clinically normal, the experiment was initiated. This experimental study was divided in two phases. The first phase lasted 48 hours. This was the control period and the animals served as their own control. The second phase was the metabolic alkalosis induction period brought about by opening the duodenal cannula to let the abomasal content flow out of the body until inducing metabolic hypochloremic alkalosis determined in blood using the iStat® blood gases analyzer. Urine samples were taken every 24 hours in both phases.

In the urine several variables were assessed such as: pH was measured using a Schoot Lab 8500 potentiometer, net acid excretion (NAE) by the Jørgensen's method that allows to calculate ammonium content and titrable acidity in urine. SID and urinary pH were calculated according to the method proposed by Constable et al (2009) where SID = NBE (Net Base Excretion)+ 2,6 = -NAE + 2,6 and pH = log₁₀ { 2 ([SID] + [NH₄]) / { (K₁' S P_{CO2} + Ka₂ [PO₄]⁻ - Ka₂ ([SID] + [NH₄])) + (K₁' S P_{CO2} + Ka₂ ([SID] + [NH₄] + Ka₂ [PO₄]⁻)² - 4 Ka₂² ([SID] + [NH₄]) [PO₄]⁻)^{1/2} }. The statistical analysis consisted of determining the degree of correlation between SID and urinary pH (measured and calculated ones; and between calculated and measured pH using Pearson's coefficient (r) at a significance level of p<0.01.

Results: It was found in the urine of sheep with experimental induced metabolic hypochloremic alkalosis, that there was a strong correlation between the measured pH and calculated pH (r= 0.847). It was also determined a strong correlation between calculated pH and SID (r=0.839). However, the correlation observed between the calculated urine SID and the measured urine pH was moderate (r=0.588). It was determined that when the experimental subjects develop paradoxical aciduria, there was an important decrease in ammonium concentration that varied from a mean range level of 1.750-2.667 mmol/L during the control phase to 4.667 to 16.250 mmol/L and the urine calculated SID showed also a marked decrease, it went from a range of 133,671 -208.779 mmol/L during the control period to 98.433 to -7.900 mmol/L during paradoxical aciduria.

Conclusions: There is a high correlation between the calculated urine pH using the formula based on SID and measured pH, the SID and calculated pH along with a moderate correlation between measured pH and calculated SID. This indicates that Urinary pH is strongly dependent of SID and pH reduction can be explained by a decrease in the SID.

Fungal rhinitis associated with tracheal collapse in a cow

Gabriela G. Rivera ¹;Daniela J. Queiroz ^{1,2};Gabriela M. Bueno ¹;Vanessa B. Paula ¹;Yuri S. Bonacin ¹;Nara S. Bernardi ¹;Vinícius A. Canello ¹;Luiz Carlos Marques ¹;José C. Lacerda-Neto ¹;Luiz Cláudio N. Mendes ³;Lina Maria W. Gomide ^{1,3}

¹Departamento de Clínica e Cirurgia Veterinária, Unesp Jaboticabal, Jaboticabal, ²Centro Universitário Barão de Mauá, Ribeirão Preto, ³Departamento de Clínica, Cirurgia e Reprodução Animal, FMVA - Unesp Araçatuba, Araçatuba, Brazil

Objectives: The incidence of respiratory diseases in cattle is high and there are several pathological agents of respiratory disease in this specie. In some cases, complementary exams such as endoscopy and microbiological culture may be necessary for the specific diagnosis of

these diseases. The aim of this study was to report a case of fungal rhinitis associated with tracheal collapse in a cow.

Materials and Methods: A seven-year-old Holstein cow was referred to the Teaching Veterinary Hospital of the FCAV – Jaboticabal, campus of the Univ. Estadual Paulista “Júlio de Mesquita Filho” - Unesp, with severe inspiratory dyspnea and orthopneic position. Physical exam revealed tachycardia (60 beats per minute), tachypnea (26 respiration per minute), pale mucous membranes and fever (40.9°C). Pulmonary auscultation revealed bilateral crackles sounds and the owner report a previous treatment for pneumonia with penicillin. Antimicrobial therapy was instituted with enrofloxacin (4mg/kg), for 14 days, every 24 hours, with slight clinical improvement. Then an endoscopy was realized and showed redness, edema and fibrinonecrotic lesions on the nasal choanae, with reduction of the nasal lumen and tracheal collapse. A nasal swab was realized for microbiological culture.

Results: Due to the appearance of lesions and lack of resolution of the case with antibiotics, we suspected of fungal infection and introduced a treatment with 20 % solution of sodium iodide (66mg/kg), every 15 days, until clinical improvement, totalizing five administrations. The fungal culture was negative, but the antifungal treatment was maintained due to clinical improvement. The swab result was positive to *Streptococcus* sp. and *Staphylococcus* sp, but the clinical signs did not justify this result. At the end of the treatment, another endoscopy was performed and showed significant improvement of lesions, including tracheal collapse.

Conclusions: The endoscopy exam was essential to determinate the exact location and magnitude of injuries, enabling the monitoring of treatment and evaluate their effectiveness. It also allowed the prognosis evaluation, since the tracheal collapse explain the slight breathing difficult that animal still presents and probably will follow for the rest of the animal's life.

Direct magnesium hydroxide abomasal infusion for ulcer treatment in cow

Daniela Queiroz^{1,2} Flávia A. Molezini¹ Juliana Paula S. Mendonça¹ Samuel S. Sousa^{1,2} Antônio Fernando Bariani Junior^{1,2} Vinicius S. V. Dias¹ Deborah P. M. Dias^{1,2}

¹Centro Universitário Barão de Mauá, Ribeirão Preto, ²Departamento de Clínica e Cirurgia Veterinária, Unesp Jaboticabal, Jaboticabal, Brazil

Objectives: Metabolic diseases, lactational stress and nutritional deficiencies are commonly observed in dairy cattle. These disorders are associated with greater digestive capacity and corporal depth due to continuous genetic selection for high milk production, leading to susceptibility for left and right-side abomasal displacement, abomasal ulcers and impactations. The aim of this study was to report a case of abomasal ulcers treated with infusion of magnesium hydroxide directly into the abomasum.

Materials and Methods: A two-year-old Holstein-Friesian cow was referred to Centro Universitário Barão de Mauá Veterinary Hospital with inappetence and marked drop in milk production. Upon physical examination, ruminal movements were present but decreased in frequency and intensity and there was a characteristic tympanic resonance (“ping”) during percussion on the left side of the abdomen, dorsally. The animal also had melena and pale mucous membranes and laboratorial findings included slight decrease in red cell count ($4.6 \times 10^6/$

μ l), featuring left-side displacement of the abomasum and perforating abomasal ulcers.

Results: Surgical treatment was elected through abomasopexy by left flank laparotomy. After surgery, two administrations of magnesium hydroxide solution were performed directly into the abomasum (300 g/450 kg BW weight), with a 4-day interval. A spine needle (20 GA, 20 cm) was used to infuse magnesium hydroxide solution, and the procedure were guided by ultrasound. Omeprazole (6 mg/kg) was administered during 7 days. Antimicrobial therapy was also instituted with oxytetracycline (20mg/kg), for 14 days, every 24 hours. Nineteen days after surgery the clinical signs of abomasal ulcers disappeared.

Conclusions: Although described as a difficult procedure, the infusion of magnesium hydroxide solution direct into the abomasum was possible following abomasopexy, and associated with omeprazole therapy, were effective in controlling the condition.

Pathological and molecular confirmation of transplacental transmission of OvHV-2 in sheep-associated malignant catarrhal fever of cattle

Selwyn Headley^{1,2} Luciano A. Pimentel² Victor H. S. Oliveira¹ Hugo S. Toma² Alice F. Alfieri¹ Natalia G. Gimenez¹ Armando D. M. Carvalho² Priscila F. M. L. Gomes² Letícia S. V. Souza² Marcelo D. Santos² Amauri A. Alfieri¹

¹Department of Veterinary Preventive Medicine, Universidade Estadual de Londrina, Londrina, ²Faculty of Veterinary Medicine, Universidade de Cuiabá, Cuiabá, Brazil

Objectives: Sheep-associated malignant catarrhal fever (SA-MCF) is an important infectious disease of ruminants worldwide that is caused by ovine herpesvirus 2 (OvHV-2). OvHV-2 is transmitted predominantly by contact between infected and susceptible hosts, while the documentation of vertical transmission is rare. This report presents the pathological and molecular findings associated with transplacental transmission of OvHV-2 in cattle

Materials and Methods: A 3-year-old Holstein-Gir cow, located at a farm in central west Brazil, was examined at the Universidade de Cuiabá. This farm contained 250 cattle and small flock of sheep. Clinically, there was corneal opacity, lachrymation, bilateral, mucopurulent nasal discharge, fever, apathy, with ulcerative lesions at the oral cavity. In addition, the cow was bearing a four-month-old foetus. The clinical condition of the cow deteriorated, resulting in spontaneously death. A routine necropsy was done soon after death. Tissue fragments from the brain, lungs, kidneys, liver, and myocardium of the cow and her fetus (myocardium, lungs, kidneys, and liver) were routinely processed for histopathological evaluation. Selected tissue sections of the cow (brain and kidney) and foetus (brain) were maintained at -80°C until used for molecular diagnostics. DNA extracted from the brain (foetus and pregnant cow) was used in PCR assays designed to amplify specific amplicons of the OvHV-2 tegument protein gene, the glycoprotein C gene of BoHV-1, BoHV-5, and the 16S rRNA gene of *Histophilus somni*. Positive and negative controls were included in all PCR assays. All PCR products were separated by electrophoresis in 2% agarose gels, stained with ethidium bromide, and examined under UV light. The amplified PCR products were then purified and submitted for direct sequencing using the forward and reverse primers. The partial nucleotide sequences obtained were initially compared by the BLAST program with similar sequences

deposited in GenBank. Sequence alignment and phylogenetic tree were then created.

Results: The principal gross findings of the cow included corneal oedema of the right ocular globe, fibrinopurulent bronchopneumonia, petechial haemorrhages at the mesentery, thoracic, and pleural surfaces, ulcerative stomatitis and rhinitis, pulmonary oedema, lymphadenopathy, and bilateral multifocal haemorrhagic nephritis. A normal looking 30 cm in length (Crown-Rump) foetus was found within the placenta. Histopathological evaluation of the tissues from the cow revealed lymphoplasmacytic, necrotizing vasculitis within the kidneys, carotid rete mirabile, brain, lymph nodes, and lungs with lymphoplasmacytic meningoencephalitis and nephritis. The PCR assay amplified the desired amplicons of the tegument protein gene of OvHV-2 from the brain and kidney of the cow, and the brain of the foetus. Direct sequencing was done with PCR products derived from the kidney of the cow and brain of her foetus. Initial BLAST analyses revealed that these sequences share 98 - 99% identity with similar sequences deposited in GenBank. The phylogenetic tree clustered the two strains of OvHV-2 with other OvHV-2 viral sequences identified in ruminants from Brazil and wild ruminants from Germany. Moreover, the generated sequence identity matrix and sequence alignment demonstrated that the nucleotide sequences of these two strains (cow and her foetus) are 100% identical. Additionally, the bovine herpesvirus type 1 (BoHV-1), BoHV-5, and H. somni PCR assays yielded negative results.

Conclusions: The clinical and pathological findings observed in this cow and her foetus are similar to those frequently observed in cattle with SA-MCF, and are the characteristic diagnostic features of this disease. Additionally, the amplification and sequencing of OvHV-2 from the brain of the cow and her foetus confirmed the likely participation of this pathogen in the development of the pathological lesions observed. These findings suggest the involvement of this pathogen in the lesions described and demonstrated the transplacental transmission of OvHV-2 in SA-MCF of cattle.

Lesions and Microbiological Findings Associated with *Mycoplasma bovis* -infection in Finland

Paula Syrjälä^{1*} Annette Brockmann¹ Minna Nylund² Kirsi Collin³ Teija Kokkonen⁴ Vera Haapala⁵ Tiina Autio⁶ Tarja Pohjanvirta⁶

¹Production Animal and Wildlife Health Research Unit, Finnish Food Safety Authority Evira, Kuopio, ²Production Animal and Wildlife Health Research Unit, Finnish Food Safety Authority Evira, Oulu, ³Production Animal and Wildlife Health Research Unit, Finnish Food Safety Authority Evira, Seinäjoki, ⁴Production Animal and Wildlife Health Research Unit, Finnish Food Safety Authority Evira, ⁵Department of Production Animal Medicine, University of Helsinki, Helsinki, ⁶Veterinary Bacteriology Research Unit, Finnish Food Safety Authority Evira, Kuopio, Finland

Objectives: *Mycoplasma bovis* was detected in Finland for the first time in 2012. By November 2015 *M. bovis* has been confirmed in 52 farms: 17 dairy herds and 35 meat producing farms. The aim of this study was to describe the lesions and microbiological findings in samples in which *M. bovis* was detected by culture.

Materials and Methods: Bovine carcasses or tissue samples from altogether 1509 cases, excluding abortion, were examined pathologically in the diagnostic laboratory service of the Finnish Food Safety Authority (Evira) from January 2012 to November 2015. The diagnostic laboratory findings were reviewed.

All samples were analysed grossly and specimens for histopathology, bacteriology and virology were taken and analysed with standard methods when appropriate. When pneumonia, arthritis or otitis media was diagnosed macroscopically, samples were examined also for *M. bovis* and ureaplasma.

Conventional aerobic, microaerophilic and anaerobic cultivation methods were used for bacterial isolation. *Histophilus somni* was identified from culture using PCR. Bovine respiratory syncytial (BRSV) virus and bovine coronavirus (BCV) were detected with PCR. *Mycoplasma* and ureaplasma were cultivated in specific culture medium (in CO₂) and confirmed with PCR. If a serum sample was available, it was tested for *M. bovis* antibodies with ELISA (BIO K 260, Bio-X Diagnostics, Rochefort, Belgium).

Results: Pneumonia was diagnosed in 26%, arthritis 4% and otitis media in 1% of the pathological samples. *M. bovis* was identified in 38 samples (3%) including 24 carcasses and 14 tissue samples. Most of the *M. bovis* positive cases were calves under three months old (35%), 24% were 3-6 months, 22% were 6-12, and 16% were over 12 months old.

The most common pathological finding connected to *M. bovis* was pneumonia (35/38). Six calves had pneumonia and otitis media and two calves had pneumonia and arthritis. In two cases only otitis media was diagnosed and in one case only arthritis in a cow. Pneumonia was classified as: Acute/subacute severe fibrinosuppurative (9/38), acute/subacute severe fibrinosuppurative with concurrent chronic lesions (11), local chronic suppurative bronchopneumonia (11), and cases with only fibrotic healing lesions (4).

Multifocal eosinophilic caseonecrotic lesion typical of *M. bovis* infection was seen in 63% of the histological sections (21 lung and one synovial sample). Necrotic foci were recorded in all classes of pneumonia cases.

Other pathogens were isolated in 25/38 (66%) of the *M. bovis* positive lung samples: *Pasteurella multocida* (14), *Histophilus somni* (12), *Ureaplasma diversum* (8), *Trueperella pyogenes* (6), *Fusobacterium* sp. (5), *Mannheimia haemolytica* (1) and *Bibersteinia trehalosi* (1). BRSV was detected in 4 cases and BCV in 3 samples.

Serum samples were available from 24 of the 38 *M. bovis* positive animals and in 33 % (8/24) *M. bovis* antibodies were detected with ELISA.

Conclusions: *M. bovis* was mostly associated with acute or chronic pneumonia in young animals and several other pathogens were often isolated from the same samples. Otitis media was more common than arthritis. Only one third of the serum samples tested for *M. bovis* antibodies were positive.

Low Body Condition Predisposes Dairy Cattle To Lameness

Laura V. Randall^{1,*}, Jon N. Huxley¹, Martin J. Green¹, Mizeck G. G. Chagunda², Colin Mason², Laura E. Green³, Simon C. Archer¹

¹School of Veterinary Medicine and Science, University of Nottingham, Sutton Bonington, ²The Dairy Research and Innovation Centre, Scotland's Rural College (SRUC), Dumfries, ³School of Life Sciences, University of Warwick, Coventry, United Kingdom

Objectives: The extensive impacts of lameness on herd performance have been widely reported. Low body condition score (BCS) has been identified as a risk factor for lameness; cows with BCS ≤ 2 (0 to 5 scale) have been reported as being more likely to be treated for lameness in the following 2 or > 2 to 4 months. This longitudinal study aimed to investigate the hypothesis that cows in low BCS are at increased risk of first and repeated lameness events. Effects of other risk factors such as body weight (BW) were also investigated. This work has been published open access in the Journal of Dairy Science (Randall et al., 2015).

Materials and Methods: Records were obtained for the 8 year period 1st Sept 2003 to 31st Aug 2011, from a total of 724 cows, managed at the Scotland's Rural College's (SRUC) Crichton Royal research farm. Locomotion scores (1 to 5 scale) and BCS (0 to 5 scale; 0.25 increments) were recorded weekly by trained assessors. An automatic weighing system recorded BW after milking 3 times daily. Health, production, and management data were recorded in a database. Locomotion score was the outcome variable and categorised as not lame (LS 1 to 2), mildly lame (LS 3) or severely lame (LS 4 to 5). BCS, BW and milk yield data were lagged by 2 through to 16 weeks to explore their longitudinal association with lameness. Mixed effect hierarchical models were used to explore the relationship between explanatory variables and lameness outcomes. Modelling was conducted in 2 stages;

1. Multinomial model for repeated lameness events; were used to explore the relationship between explanatory variables and long term repeated mild and severe lameness events.
2. Discrete time survival models for first lameness events in a) heifers and b) 2nd lactation and greater cows; were used to investigate the relationship between BCS and lameness, without the confounding effect of a previous lame event causing BCS loss.

Results: Descriptive statistics; The data set included a total of 79,565 cow weeks at risk. The proportion of lame observations (mild and severe) in each lagged BCS category, from 3 through to 16 weeks, had a trend of decreasing percentage of lame events from BCS < 2 to BCS > 3 ; BCS 2.5 had the lowest percentage of lame observations.

Modelling;

1. Repeated lameness events model; lagged variables for BCS and BW were correlated from 2 through to 16 weeks. Cows with BCS < 2 three weeks prior to a lameness event were at significantly greater risk of lameness compared with other BCS categories. Risk decreased as BCS increased. Low BW cows (< 550 kg category) were at significantly increased risk of mild or severe repeated lameness events compared with cows in heavier BW categories (550 – 700 and > 700 kg).
2. First lifetime lameness event models; a) Heifers; BCS and BW were not associated with an increased risk of lameness. b) ≥ 2 nd lactation cows; cows with BCS ≥ 2.5 16 weeks prior to a first mild lameness event were at reduced risk of lameness compared with BCS < 2 . The same effect was seen at BCS = 2.25 8 weeks prior to a first severe lameness event.

Conclusions: These findings indicate that BCS < 2 is associated with the greatest risk of mild or severe lameness, and that risk decreases with increasing BCS. Results suggest that maintaining BCS ≥ 2.5 may be optimal for reducing the risk of lameness in dairy cows. These findings were relevant for long-term repeated lameness events and first time lameness events in second lactation and greater cows. Low BW (independent of BCS) was also identified as an important risk factor for lifetime risk of repeated lameness events. This study provides evidence to support targeting management towards maintaining BCS to reduce the risk of lameness in dairy herds.

Cross sectional study on prevalence of lameness and foot disorders influencing welfare of Mediterranean buffaloes

Jacopo Guccione^{1,*}, Christian Carcasole², Maher Alsaad³, Luigi D'Andrea¹, Antonio Di Loria⁴, Angela De Rosa¹, Paolo Ciaramella¹, Adrian Steiner³

¹Department of Veterinary Medicine and Animal Production, University of Study of Napoli "Federico II", Napoli, ²Veterinary practitioner, Latina District, Latina, Italy, ³Clinic for Ruminants, Department of Clinical Veterinary Medicine, Vetsuisse-Faculty, University of Bern, Bern, Switzerland, ⁴Department of Health Science, University of Magna Graecia of Catanzaro, Catanzaro, Italy

Objectives: Lameness represents the third most important health-related cause of economic loss in the dairy industry after fertility and mastitis. Although, dairy Mediterranean Buffaloes (MB) and dairy cows share similar breeding systems predisposing to similar herd problems, published studies exploring its relevance and role in these ruminants are still rare and incomplete. It was the aim of this study to assess prevalence of clinical lameness and foot disorders observed during routine foot trimming of a population of 1,297 MB housed in four different free-stalls.

Materials and Methods: Trimming procedures were performed once in all the multiparous MB (≥ 2 lactations), whether lame or not, present in the farms enrolled, between April 2014 and March 2015 in Latina District, Middle of Italy. Presence or absence of foot disorders (FDs) as well as their localization were recorded at claw trimming. Prevalence of the observed FDs, motility index (number of cows not lame/number of multiparous cows in the herd) and lameness index (number of cows lame/number of multiparous cows in herd) were also calculated. Locomotion score [LS; from 1 (non-lame) to 5 (severely lame)], body condition score [BCS; from 1 (emaciated) to 5 (obese)] and cleanliness score [CS; from 1 (no manure) to 4 (manure up to the leg)] were

evaluated of each MB affected by FD and used as welfare indicators. For descriptive statistical analyses, dedicated software (SPSS, Version 17.0, Chicago, IL) was used.

Results: The overall prevalence of animals affected by FDs was 17.65% (229/1,297), while motility and lameness index were 84.12% (1,091/1,297) and 15.88% (206/1,297), respectively. Claw overgrowth (OG) was present in 96.06% (220/229) of cases with FD, corkscrew claw (CC) in 89.52% (205/229), interdigital phlegmon (IP) in 5.24% (12/229), white line abscess (WLA) in 4.80% (11/229), digital dermatitis (DD) in 0.44% (1/229) and interdigital hyperplasia (IH) in 0.44% (1/229). Simultaneous presence of two disorders was recorded in 96.51% (221/229) of MB: OG + CC occurred together in 92.76% (205/221), OG + IP in 1.81% (4/221), DD + IH in 0.45% (1/221) and OG + WLA in 4.98% (11/221). No lameness caused by orthopedic pathology located outside the feet was detected during the investigation. Except from 23 MB with simultaneous occurrence of OG + CC, the presence of FDs was always associated with lameness (LS>2). Regarding the BCS, none of the MB with FDs were over-conditioned (BCS \geq 3.75), while 80.35% (184/229) were normal-conditioned (BCS \geq 2.75 and \leq 3.5) and 19.65% (45/229) were under-conditioned (BCS \leq 2.5). The CS was 4 in 50.22% (115/229) of MB affected with FDs, while it was 3 in 9.61% (22/229), 2 in 6.55% (15/229) and 1 in 33.62% (77/229).

Conclusions: During the current investigation, FDs still considered virtually absent in MB until now, were detected associated with clinical lameness and decrease of animal welfare. Although characterized by a lower prevalence than in dairy cows, disorders not only related to heritable factors but also to poor herd health management were observed for the first time also in these dairy ruminants

Lameness

P03-003-150

The Icar Claw Health Atlas – The Result Of An International Cooperation Of Claw Health Experts For Harmonization Of Terminology Of Bovine Claw Lesions

Johann Kofler^{1,*}

¹Department of Farm Animals and Veterinary Public Health, Clinic for Ruminants, University of Veterinary Medicine Vienna, Vienna, Austria

Objectives: Documentation of claw health data during regular trimming visits has been identified as a valuable source of information on claw disorders on a cow and a herd level. However, heterogeneous documentation practices complicate their routine collection and use for genetic evaluation of claw health.

In 2014, the ICAR Working Group for Functional Traits (ICAR WGFT) started an initiative together with international experts with the aims to assess the situation of recording of claw health in the different member countries, and to establish an international harmonization of the definitions of claw disorders and a standardization of their terminology.

Materials and Methods: An online-survey was carried out in 2014 among the 53 ICAR member countries. Based on the results, a list of claw disorders/lesions that were regarded to be relevant for documentation of claw health in dairy cows and for genetic evaluations was elaborated following several meetings and online conferences. After the harmonized descriptions of claw lesions were agreed by ICAR WGFT, high-quality photos of each of the claw disorders/lesions were collected, and the most representative examples were selected by voting. The harmonized

definitions of claw lesions and the selected illustrations were the basis of the new ICAR Claw Health Atlas.

Results: Responses from 18 of 53 countries (34%) showed that around half of them have a single national key for recording claw and foot disorders. Information is collected in these countries on 6 to 20 different disorders, in many of them with severity grades. Professional hoof trimmers were found to be the main source of claw data, often using hand-held electronic recording devices and herd management software (Fig. 1; 11 countries). However, use of paper forms is still common, and it was assumed that many claw trimming events are not documented at all. No exact figures about the documented and centrally recorded claw health information relative to the percentage of dairy cows under regular milk recording are available. In countries with routine genetic evaluations for claw health, data from claw trimming are already stored in a central database and are also used for herd management.

For 16 claw disorders/lesions harmonized descriptions (Fig. 2, 3) were established and, illustrated by representative photographs, assembled to the first internationally agreed reference, the ICAR Claw Health Atlas. This Atlas of 16 claw disorders/lesions was published in the official ICAR language (English) and is now available for translation into other languages for distribution to professional trimmers and farmers worldwide. Information on translation and access to a high-quality print version are provided by ICAR. The English version is freely available online for download on the ICAR website: http://www.icar.org/Documents/ICAR_Claw_Health_Atlas.pdf

Conclusions: The international collaboration of the ICAR WGFT and international claw health experts provided for the first time a harmonization of terminology and definitions of claw disorders in cattle. One key aspect of successful initiatives to build routine genetic evaluations for claw health is the development of an infrastructure for electronic documentation of claw health data on a national basis. The other important key aspect providing the collection of high quality data is the use of a standardized terminology of claw lesions worldwide, which is now provided with the ICAR Claw Health Atlas as a guideline.

Comparison of the true lameness prevalence in dairy herds with its estimation by dairy farmers and herd health veterinarians

Jocelyn Dubuc^{1,*} Véronique Fauteux¹

¹Faculté de médecine vétérinaire, Université de Montréal, Saint-Hyacinthe, Québec, J2S 7C6, Canada

Objectives: Lameness prevalence in dairy herds can be determined using lameness scoring charts. The use of these charts is semi-quantitative and helps users to identify lame cows (especially slightly lame cows). Unfortunately, dairy farmers and herd health veterinarians rarely spend time assessing lameness prevalence in Québec (Canada). Thus, it remains unclear if their estimation of lameness prevalence in herds is accurate or not. The objectives of this study were to quantify the lameness prevalence in dairy herds from a specific veterinary practice and to compare this prevalence to its estimated values from dairy farmers and herd health veterinarians.

Materials and Methods: A cross-sectional study was conducted on 20 commercial dairy herds that were clients of the bovine ambulatory clinic of the Faculté de médecine vétérinaire of the Université de Montréal

(Saint-Hyacinthe, QC, Canada). Herds were visited once by two trained observers (research veterinarians) to score lameness and to quantify the herd lameness prevalence. Lameness was score based on standard a 5-point scoring chart. Before lameness scoring was initiated at the farm, the farm's owner and herd health veterinarian had to independently estimate the lameness prevalence of the herd. Everybody was blinded to each other's result. True lameness prevalence was calculated. The difference between true lameness and its estimations from farmers and veterinarians were also calculated and compared with a t-test. Inter- and intra-observer agreements were calculated for both research veterinarians.

Results: The median true lameness prevalence was 25 % with a range from 11 to 65 %. On average, dairy farmers underestimated the lameness prevalence of their herd by 13 percentage points (ranged from underestimation of 45 % to overestimation of 10 %; $P < 0.01$). On average, herd health veterinarians estimated a similar prevalence in their herds compared with the true prevalence (ranged from underestimation of 20 % to overestimation of 20 %; $P = 0.68$). Inter- and intra-observer agreement (κ) from research veterinarians were 0.84 and 0.86, respectively.

Conclusions: Overall, these results suggest that dairy farmers generally underestimate the prevalence of lameness in their herd. They also suggest that herd health veterinarians can generally estimate well the lameness prevalence in herds. Finally, they suggest that trained observers performing lameness scoring can provide very similar results.

Distal sesamoid bursa in cattle: radiography, fluid taking, injection techniques and fluid analysis

Meimandi Abdolhamid¹, Saeed Nazifi¹, Moosa Javdani²

¹Clinical Sciences Dept, Shiraz University, Shiraz, ²Clinical Sciences Dept, Shahrekord University, Shahrekord, Iran, Islamic Republic Of

Objectives: A common area of lameness in cattle is the digital region, especially the distal sesamoid bone, distal sesamoid bursa (DSB) and distal interphalangeal joint. A few techniques for injection into the distal sesamoid bursa (navicular bursa) or fluid taking have been described in cattle. In this study different techniques for approaching to DSB were compared. In another study physical, biochemical and cellular evaluations of the synovial fluid of the DSB were compared in normal and abnormal claws in cattle.

Materials and Methods: Five different techniques for entering to DSB were compared in cattle including distal plantar approach parallel with the coronary band, proximal plantar approach, distal plantar approach parallel with the sole, abaxial approach, and distal interphalangeal joint injection. For the approaches radiography was also used. In 22 normal (11 rear limbs and 11 forelimbs) and 27 abnormal (16 rear limbs and 11 forelimbs) hooves of both sexes of Holstein cows, the synovial fluid were collected from the DSB. Fluid was taken from the sesamoid bursa by the technique of previous study. Clinical observation of the animals before slaughtering, grass evaluation and radiographic interpretation of the hooves were the basis for allocation to either the normal or abnormal group. Physical characteristics of fluid, total nucleated cell counts, differential cell counts, protein and glucose concentrations and the activities of some enzymes were measured by standard methods.

Results: Actually the placement of the needle through distal plantar

approach parallel with the sole was the best for fluid taking or injection. The results of fluid analysis of bursa showed the parameters of DSB fluid are the same as other synovial fluids in cattle. The results revealed that the enzyme activity of the abnormal synovial fluid from the DSB significantly increased. Also, there were no significant differences between the mean concentrations of total protein in the normal and abnormal synovial fluid specimens.

Conclusions: Placement of the needle through distal plantar approach parallel with the sole was the best for fluid taking or injection. Although there was no significant differences of some cellular and biochemical parameters of synovial fluid, the differences of these variables in normal and abnormal hooves may be useful for the diagnosis of healthy and abnormal synovial fluid.

Reducing lameness in organic dairy herds following farm individual intervention measures

Jan Brinkmann¹, Solveig March¹, Kerstin Barth¹, Christoph Drerup², Johannes Isselstein³, Doris Klocke⁴, Volker Krömker⁴, Ferdinand Mersch², Jürgen Müller⁵, Petra Rauch⁶, Ulrich Schumacher⁷, Hubert Spiekers⁶, Arne Tichter³, Otto Volling⁷, Martin Weiler⁷, Martin Weiss⁷, Christoph Winckler⁸

¹Thuenen-Institute of Organic Farming, Westerau, ²Chamber of Agriculture North Rhine-Westphalia, Muenster, ³Georg-August-University of Goettingen, Goettingen, ⁴University of Applied Sciences and Arts, Hannover, ⁵University of Rostock, Rostock, ⁶Bavarian State Research Center for Agriculture, Freising-Weihenstephan, ⁷Bioland, Mainz, Germany, ⁸University of Natural Resources and Life Sciences, Vienna, Austria

Objectives: Between 2007 and 2010 a nationwide interdisciplinary intervention study was carried out in 106 German organic dairy farms in order to develop preventive animal health management strategies for mastitis and metabolic disorders and to validate this concept (Brinkmann et al., WBC 2012). Lameness is a risk factor for metabolic disorders in dairy cows and affects animal welfare. Thus, the aim of the present study was also to reduce lameness prevalence by farm-individual intervention measures related to housing and management.

Materials and Methods: Average herd size was 57 cows (range 18-252) and average milk yield 6,053 kg per cow and year (range 3,424-8,917). The initial farm visit focused on the health situation (here: lameness assessment through locomotion scoring using a 3 point scale according to the Welfare Quality® (2009) Assessment protocol for cattle) and a range of potential risk factors including housing, herd management, feeding and forage production. Using this information, farm-individual evidence-based advice was provided by the project team and discussed with the farmers. Interdisciplinary intervention measures to improve udder and metabolic health were implemented in all farms and lameness was specifically addressed in 28 farms. The most frequently implemented measure was the introduction of a regular functional claw trimming or a shorter claw trimming interval (18 farms) followed by measures such as improvement of the cubicle base and of floor properties in the alleys (e.g. grip, deburring of edges, cleaning frequency) (10 farms). Effectiveness of intervention was monitored after one and two years, respectively (in total four farm visits within two years). Mixed models for repeated measures were used to analyse lameness prevalence at herd level.

Results: The average baseline lameness prevalence in all 106 project farms (visit 1) was 17.3 % and ranged from 0 to 63 %. Cubicle housed

herds tended to show more lameness (18.2 %, 88 farms) than cows kept in straw yard systems (12.6 %, 18 farms; $p=0.068$, Wilcoxon test). In the course of the observation period, lameness prevalence decreased to 13.2 % (visit 4; range 0 – 63 %). Considering the 28 farms which implemented measures specifically intended to improve the lameness situation, lameness prevalence significantly decreased from visit 1 to visit 4 (26.1 -> 15.9 %, $p<0.001$) whilst it did not change in the remaining 78 farms (control group) (13.4 -> 12.2 %, ns). Furthermore, intervention farms showed a significant reduction in prevalence of severely lame cows from visit 1 to visit 4 (9.3 -> 4.2 %, $p<0.001$) whereas there was again no significant change in control farms (4.6 -> 3.6 %, ns).

Conclusions: Our study showed that prevalence of lameness in organic dairy cows may be reduced by implementing farm-individual intervention measures. The results demonstrate the benefits of preventive herd health concepts: dairy farmers who implemented farm-individual intervention measures related to housing and management successfully reduced lameness in their herds. We therefore expect our findings to encourage the implementation of preventive herd health concepts in organic dairy farming.

Comments: The authors warmly thank the participating farmers for their interest and willingness to participate in the study and their generous hospitality. Furthermore the Federal Agency for Agriculture and Food (BLE) is gratefully acknowledged for financial support in the context of the Federal Organic Farming Scheme (BÖL), grant no. 07OE012-022 'Health and performance of dairy cows in organic farming'.

P03-003-154

Identification of BDD-associated treponemes in Brazilian cattle

Sabine Brandt ¹Sabine Sykora ¹Daniel Ollhoff ² and Research Group Oncology, Equine Clinic, Veterinary University of Vienna, Austria

¹Research Group Oncology, Equine Clinic, University of Veterinary Medicine, Vienna, Vienna, Austria, ²PUCPR, Universidade Catolica do Parana, Parana, Brazil

Objectives: Bovine digital dermatitis (BDD) is an infectious foot disease that seriously compromises the welfare and productivity of affected cattle. Disease is currently assumed to be of multifactorial origin, with treponemes and possibly other, thus far unidentified infectious agents having a major role in BDD development and persistence. Here, BDD tissue obtained from 35 bovines in Paraná, Brazil, was assessed for the presence of treponemal DNA, and the most abundant Treponema types per lesion were identified.

Materials and Methods: Collected BDD tissue was subjected to DNA extraction using a commercial kit, followed by beta action PCR to confirm the PCR-compatibility of obtained DNA isolates. Then, the latter were PCR screened for the presence of treponemal DNA using a pair of pan-Treponema primers, i.e. 5'TT and 3'TT, as already published. Sterile water and Treponema-free bovine tissue DNA served as no template and negative controls. Amplification products were analysed by gel electrophoresis and visualized by ethidium bromide staining. Amplicons of sufficient quantity and anticipated size were gel-extracted and subjected to bi-directional sequencing.

Results: In total, 32 of 35 BDD DNA isolates scored positive by TT-PCR, presenting as weaker bands in 8, and as prominent bands in 24 cases. Gel extraction and subsequent bi-directional sequencing of the

latter resulted in the identification of the most abundant Treponema types present in the individual lesions, i.e. Treponema pedis in 9, T. phagedenis and T. medium in 5 cases each, feline oral treponemes in 4, T. refringens in 3, T. putidum in 2, and T. denticola and canine oral treponemes in one lesion each. A single Treponema type was detected in 15, two types in 9 of the 24 lesions.

Conclusions: As expected, the majority of BDD lesions tested positive for treponemal DNA. Overall, T. pedis, which is commonly found in BDD lesions in central Europe and the UK, was most frequently detected in Brazilian cattle. This observation further supports the concept of a causal association of T. pedis with BDD. In contrast, the Brazilian cows harboured typically BDD-associated treponemes such as T. medium, T. denticola, or T. phagedenis to a much lesser extent than European BDD-affected cattle, indicating that BDD-associated Treponema types vary geographically. However, more work and larger sample sizes are needed to confirm this theory.

Comments: Interestingly, four different lesions were shown to harbour feline oral Treponema types. In analogy, it could be shown previously that BDD lesions of Austrian cattle frequently contain canine oral treponemes. These findings emphasize the wide host range of Treponema sp. and support the concept of high cross-species infection rates.

A Randomized Controlled Trial Of 50 M2 Digital Dermatitis Lesions With A Non-Antibiotic Gel Containing Chelated Copper And Zinc

Gerwen Lammers ¹Emil Sabau ²Robbert van Berkel ¹Henk van der Vegt ¹Carly Vulders ¹Koos Vis ³

¹Product Development & Regulatory Affairs, Intracare BV, Veghel, Netherlands, ²Emil Veterinary Services, Picture Butte, ³Diamond Hoof Care Ltd., Diamond City, Canada

Objectives: Digital Dermatitis (also known as Mortellaro's disease or hairy heel warts) is a chronic infection of the digital skin in cattle, causing lameness, economical loss and decreased welfare. In Europe, a non-antibiotic gel containing chelated copper and zinc has been registered for the treatment of Digital Dermatitis after clinical comparison with an antibiotic spray (Holzhauer et al., 2011). In Canada, no medication was officially registered for the treatment of Digital Dermatitis. To obtain such registration, a randomized controlled clinical trial was performed to investigate the efficacy of the non-antibiotic gel in Canadian dairy cows.

Materials and Methods: On three farms, a total of 50 active Digital Dermatitis M2 lesions were randomly divided in two groups: A) 25 lesions were treated with the non-antibiotic product (Intra Hoof-fit Gel); and B) 25 lesions were used as untreated controls.

Group A was treated with the non-antibiotic gel according to the following protocol:

Day 0: Approximately 5 grams of gel was applied on the lesion with a brush, then covered with cotton wool and maintained in place by an elastic bandage.

Day 3: The bandage was removed, and approximately 5 grams of gel was applied again with a brush, no bandage.

Day 7: Approximately 5 grams of gel was applied with a brush, no bandage.

The trial lasted for 10 days, and on day 0, 7, and 10, the animals were restrained in a hoof-trimming chute. The affected hoofs were cleaned with a towel, and lesion characteristics were scored. On day 0 and 10, a digital photograph of the lesions was taken.

In this study, "cure" was defined as the transition of the M2 type lesion to an M0, M1, M3 or M4 type lesion. All scoring and treatment of Digital Dermatitis was performed by the independent investigator (Emil Sabau). The results were statistically analyzed using a Fisher's exact test, $p < 0.05$ was considered significant.

Results: On day 7, each single lesion of the gel-treated group had already changed from a red and active M2 to the healing M3 phase covered with a scab (23 out of 25 lesions) and the non-painful chronic M4 phase (2 out of 25 lesions). This was in sharp contrast to the untreated lesions, that all remained red and active M2 lesions on day 7. On the final day, day 10, this striking difference remained unchanged. The association between groups and outcomes was statistically significant with a p value of < 0.000001 .

Conclusions: Registration of an antibiotic-free treatment for Digital Dermatitis in Canada required a clinical comparison with untreated lesions. All lesions treated with the non-antibiotic gel cured, while all untreated lesions remained active. This all-or-nothing effect confirmed the efficacy of the non-antibiotic gel as a powerful treatment for Digital Dermatitis in cattle.

Comments: Disclosure of interest: GL, RvB, HvdV and CV are employees of Intracare B.V., KV is the local distributor of Intracare hoof products in Canada.

Claw Lesions During Early Lactation Are Not Preceded By Changes In Oxidative Status From Dry-Off To Early Lactation

Angel Abuelo^{1*}, Jeff C. Gandy², Lorraine M. Sordillo²

¹Graham Centre for Agriculture Innovation, NSW Department of Primary Industries and Charles Sturt University, Wagga Wagga, Australia, ²Department of Large Animal Clinical Sciences, Michigan State University, East Lansing, United States

Objectives: Lameness is a major health disorder of dairy cattle and there is now growing evidence suggesting that lameness might be triggered during the transition period. Oxidative stress (OS) occurs during the transition period in dairy cattle and a recent study suggests that OS associated episodes of lameness. The question remains whether OS occurs due to lameness or if OS around the time of calving may precede the development of claw lesions. Therefore, this study investigated whether cows showing claw lesions during early lactation had a greater pro-oxidant and inflammatory status throughout the dry period or the start of the lactation.

Materials and Methods: For this cross-sectional study, blood samples were taken from 30 cows from the same herd at dry-off, movement to the close-up pen and between 3-7 DIM and the concentration of the acute phase proteins haptoglobin and serum amyloid A, reactive oxygen and nitrogen species (RONS) and antioxidant potential (AOP) were quantified in serum. Animals were followed up to 120 DIM

and grouped ex-post into one of the following health categories: (1) exclusively hoof lesions (HL); (2) other clinical or subclinical postpartum disease/s (OPD; such as retained placenta, metritis, mastitis, displaced abomasum, excessive lipid mobilization and/or hyperketonemia); or (3) non-diseased (ND). Three cows were culled before the completion of the study and hence their data were excluded. The HF category was finally composed by 7 cows, OPD by 12 and ND by 8 cows. Mixed models with repeated measures built on JMP Pro v11 were used to investigate the effects of time, health category and their interaction on the concentration of markers of oxidative status (RONS and AOP) and acute phase proteins.

Results: We hypothesized that those animals suffering from hoof lesions would show a higher pro-oxidant status than healthy animals during the dry period and the onset of lactation. However, contrary to our initial hypothesis, the health category did not show a significant effect on any of the oxidative status markers employed in this study. The previous studies that reported increased oxidant activity in cows with claw lesions or altered gait measured oxidative status biomarkers when the cows were already showing clinical signs. Therefore, the greater pro-oxidant state found in this studies could just have developed shortly before the onset of clinical signs of lameness, or be a consequence of the inflammation of the injured tissue.

Conclusions: The development of claw lesions during early lactation has not been associated either with a greater pro-oxidant or inflammatory status during the dry period or the start of the lactation, thereby suggesting that these changes, reported in other studies, either take place closer to the onset of clinical signs of lameness or develop as a consequence of the inflammation of the injured tissue.

P03-003-157

New ways in prevention of digital dermatitis using an organic acid based germicide

Andrea Fiedler^{1*}, Charlotte Kroeger², Katharina Schindhelm³, Johann Maierl², Anouk Lanckriet⁴, Sven Reese²

¹Praxisgemeinschaft fuer Klauengesundheit, ²Department of Veterinary Science, Ludwig-Maximilians-University, ³Bavarian State Research Center, Munich, Germany, ⁴DeLaval NV, Gent, Belgium

Objectives: Footbaths containing carcinogenic formalin or heavy metals such as copper sulfate are a commonly used tool to control prevalence of digital dermatitis in modern dairy farms. But these agents represent a serious hazard to human health and the environment. The aim of this study was to evaluate the efficacy of an alternative, organic acid based disinfectant which is less harmful, applied on every foot individually.

Materials and Methods: A total of 218 cows in two commercial dairy farms were included in the study. All animals underwent hoof trimming during the first visit (day -14). 182 feet presented with acute (M2) or chronic (M4 or M4.1) digital dermatitis lesions and were treated with salicylic acid. Success of treatment was documented. The disinfection regimen was started 14 days later (day 0): Three times a week hind feet were cleaned with a water hose in the milking parlor. After that the disinfection solution (EasyStride, DeLaval) containing lactic and formic acid, was sprayed on all right hind feet at a dilution of 4%. Left feet remained non-disinfected as a control group. Every foot was evaluated on day 0, 20, 49 and 79 following a modified DD lesion score (Doepfer 2009).

Results: On day -14 and day 0 there was no statistical difference in DD prevalence (acute DD lesions (M2): 98 feet (22%) and chronic DD lesions (M4 or M4.1) 84 feet (19%)), on day 49 ($p=0.007$) and day 79 ($p=0.01$) statistical analysis points out a significant difference between the two groups (sign test). The sprayed feet showed a significantly lower recurrence rate of clinical signs of DD than the ones that had only been washed. The pre-deluted disinfecting solution had a steady concentration of formic acid (0,45 %) and lactic acid (0,47 %).

Conclusions: In contrast to the use of footbaths where slurry contamination increases, individual application of a disinfectant after pre-washing is able to provide a steady concentration of the disinfection solution leading to better results in DD prevention. The organic acid based disinfectant meets the expectations of producers and consumers in a reliable and nonhazardous chemical. The topical spray application resulted in an acceptable prevention on new DD lesions. Additionally organic acids do not cause relevant residuals neither in milk nor in manure. It should be noted that hoof disinfection can only be part of a consequent hoof health management.

P03-003-158

Beef cattle foot health at the point of slaughter in the UK

Karin Mueller^{1,*}

¹School of Veterinary Science, University of Liverpool, Liverpool, United Kingdom

Objectives: Lameness has received little attention in beef cattle in the UK, despite being recognised as of major welfare and economic importance in dairy cattle and sheep. Scarce research in this field means that even basic information, like prevalence and common types of lesions, is lacking.

This study aims to establish whether, and to what degree, foot lesions or abnormal conformation are present in prime beef cattle at the point of slaughter.

Materials and Methods: Over 120 lower cattle limbs were collected at one abattoir over several months. Cattle were prime beef animals under 30-months-of age. Limbs were selected randomly from the waste bin, therefore no back-tracing to animal ID, exact age or breed was possible. Using claw size and shape, feet were identified as front or back, and left or right.

For claw conformation, claw length was measured along the dorsal wall, sole surface assessed for evenness and alignment with the weight-bearing wall, and height difference between lateral and medial claw noted.

The interdigital space was examined for skin disruption, infection and hyperplasia. Extent and stage was noted for any digital dermatitis lesions. Horn was removed superficially from the sole using a foot trimming knife to allow visualisation of any lesions. The presence, extent and location of any sole haemorrhage, sole ulcer, white line lesion or heel horn erosion was noted.

Results: The majority of feet displayed at least one lesion, based on preliminary analysis. Heel horn erosion and sole haemorrhage were common, with each present in about two-thirds of limbs. Interdigital hyperplasia, in contrast, was rarely present. Severity of lesions ranged from mild to severe, like a deep toe lesion or interdigital necrobacillosis.

Claw length varied from seven to ten centimetres. Occasionally, double or underrun sole horn was observed, and in about one fifth of claws the weight-bearing wall was higher than the sole surface.

Lesions were classed severe enough that the live animal would very probably have been lame in about one in five limbs (21%).

Conclusions: Feet of prime slaughter cattle displayed a high prevalence of abnormalities. Both abnormal conformation and foot lesions were found. The welfare regulations for cattle during transport and at slaughter were not fulfilled in about one-fifth of animals, in which lesions were regarded as severe enough to have resulted in lameness in the live animal.

These results suggest that foot abnormalities are present in cattle reared for meat to such a degree as to necessitate further studies.

Lameness

P03-003-159

Assessment of the footbaths contamination by dairy cattle manures under fields conditions.

Juan Manuel Ariza^{1,*}Nathalie Bareille¹Kenny Oberle²Raphaël Guatteo¹

¹UMR 1300 ONIRIS-INRA BIOEPAR, Nantes, ²Qalian, InVivo Animal Nutrition and health., Segré, France

Objectives: Infectious diseases, such as bovine digital dermatitis, became one the most important causes of lameness in dairy cattle. Among medical actions, footbaths represent a useful alternative to treat concomitantly an important numbers of animals for a given period. The active substances used in footbaths can be challenged against different amounts of organic matter (OM), temperatures and/or pH changes, which could alter their bactericidal activity. The aim of our experiment was to determine under field conditions the variations of the temperatures, pH and OM amounts in footbaths challenged against different numbers of cows which walk through them.

Materials and Methods: The experiment was carried in 5 dairy cattle farms from western France. The herds had to be (i) in zero grazing system to avoid natural cleaning of the feet on pasture, (ii) be housed in cubicles where the cleanliness of the feet is expected to be worse than in strawyard housing system, and finally, (iii) the herd size was limited to a minimum of 100 cows milked twice a day, to homogenize the sampling period to 24 hours.

The hygienic status of the farms was determined by the overall feet hygienic score of the farm based on a specific grid focusing on the feet. A footbath filled with 250 liters of water was placed at the parlour exit for 24 hours. The temperature was continuously monitored through a capture device located in the footbath and in the barn (to monitor ambient temperature). After an homogenization of the footbath content with a shovel, 3 samples (1L/sample) were taken throughout the footbath at different places after the cow passages (0 to 200), to analyze the evolution of OM content and pH. Additionally, the number of cows that defecated into the footbaths was recorded.

Results: Preliminary results indicate that the OM content rise together with the increased number of animals that walk through, and mostly, by the number of defecations into the footbath, varying from 0.086 g/L before the first passage up to 40.3 g/L after the last measure. The temperature measured in the footbath varies across the day from 12.5 °C to 18°C with less than 2% of variation in relation to the ambient temperature. Finally, the pH of the footbath varied within the 24 hours period from 6.70 to

7.76. After the first defecation the pH increased from 6.70 to 7.48, and then the measures varied in-between 7.32 to 7.76. The mean number of animals that had defecated into the footbaths rose to 10% after 200 cow passages. We are currently performing the data analysis in order to provide practical advices such as renewal frequencies or concentration of the product according to the hygienic status of the farm.

Conclusions: The results of the present finding support the need for further studies to test the effectiveness of disinfectant in presence of different OM content or pH conditions to adapt, if necessary, the concentration of the product in the footbath or the frequency of renewal.

P03-003-160

Inter-observer agreement between foot trimmers on foot lesions in cattle

Mark Burnell¹*Nick Bell²Jo Rossiter²Steve van Winden²

¹Cattle Lameness Academy / Synergy Farm Health, Evershot, ²Royal Veterinary College, London, United Kingdom

Objectives: The majority of lameness cases are caused by foot lesions and it has been suggested to target lesion-specific causes of lameness in a herd, rather than making generalised preventative changes. Drawing conclusions about the epidemiology and risk factors for specific lesions from existing studies is problematic. In order to research the epidemiology and risk factors for specific causes of lameness further, a standardised protocol for categorising foot lesions is needed. The aim of this study was to evaluate the inter-observer agreement between 5 foot trimmers from one vet practice when recording foot lesions in cattle.

Materials and Methods: A variety of photographs of foot lesions was obtained from several archives belong to the authors and in total included 13 different lesions with 6 pictures of each type. 5 hoof trimmers working for the veterinary practice with varying years of experience were gathered together and shown each picture for up to 1 minute and asked to write down the name (colloquial terms were accepted) of the main lesion they observed. The results of each observer were compared with a 'gold standard' diagnosis which was made by an experienced veterinary practitioner. The percentage agreement (sensitivity), specificity and kappa statistic were calculated for each lesion and the strength of agreement was determined.

Results: The kappa value is a means of measuring the agreement between individuals with a maximum score of 1 indicating perfect agreement. On the basis of the kappa values, sensitivity and specificity the strength of agreement for each lesion was classified excellent, substantial or poor. Results indicated that the trimmers had good agreement (excellent or substantial) for the identification of solar ulceration, white line disease, toe necrosis, sole haemorrhage and horizontal and vertical wall fissures but poor agreement for digital dermatitis, interdigital necrobacillosis, heel horn erosion, interdigital hyperplasia, sole penetration, sole separation and 'bulb infection'.

Conclusions: Finding poor observer agreements is useful in alerting us to the need to improve training for foot trimmers or redefine the categorisation of these lesions. The variable results between lesions emphasises the importance of recording inter-observer agreement when carrying out studies focussing on specific foot lesions. The specificity of the lesion scoring was high, suggesting when a lesion is identified, it is identified correctly. The low sensitivity for some lesions suggests that

some lesions may be missed by the foot trimmer but may also reflect the limitations of assessing a lesion by looking at a picture.

P03-003-161

High within- and between-observer agreement can be achieved in different professional groups applying a video mobility scoring system of dairy cows

Emanuel Garcia¹*Kamilla König¹Bodil H. Allesen-Holm²Ilka Christine Klaas¹Jose M. Amigo³Rasmus Bro³Carsten Enevoldsen¹

¹Department of Large Animal Sciences, ²Department of Food Science, Sensory and Consumer Science, ³Department of Food Science, Spectroscopy and Chemometrics, University of Copenhagen, Frederiksberg, Denmark

Objectives: Mobility scoring is widely used to monitor lameness prevalence in dairy cows. To ensure data validity, high within- and between-observer agreement is necessary. A video-based mobility scoring system offers the opportunity to assess groups of observers under standardized conditions. The objective of our study was to investigate within- and between-observer agreement of farmers, bovine practitioners, veterinary students, researchers and a cattle-inexperienced food sensory panel. Further objectives were to investigate the effect of educational background and preferences when assessing gait attributes.

Materials and Methods: An online questionnaire with video samples was developed based on recordings of lactating dairy cows walking on slatted floor. The König-Garcia mobility score (ranging from score 1 to 5) was developed following guidelines from sensory science (Garcia et al., 2015). This score evaluates cows during walking and does not require a cow standing. Video sequences were obtained in four herds and the sequences shortened and allocated into two tests, test A and test B. Each test consisted of 11 unique video sequences (11 cows) shown in replicates at random order. The authors assigned a reference mobility score to each video sequence. The different professional groups were tested at seven independent sessions with a total of 102 observers. The sessions were organized in: Introduction to test and König-Garcia mobility score, test A, short training session with cases, break, test B, final questions on preferred gait attributes. The data was analyzed using kappa coefficients and logistic regression models

Results: Crude weighted kappa for within-observer agreement in test A and test B ranged from 0.76 to 0.80 and 0.70 to 0.75. Combining both tests, sensory assessors had the lowest probability of perfect agreement with 55%, while fourth-year veterinary students had the highest with 72%, when adjusted for fixed effects of video sample and preferred attribute. In general, the differences between groups were low and even inexperienced observers achieved perfect within-observer agreement of 60%. Observers preferring the attributes arched back or the overall mobility score achieved highest perfect agreement.

The between-observer agreement was assessed by weighted Kappa and ranged from 0.67 to 0.72 in test A and 0.58 to 0.69 in test B. A higher level of between- and within-observer agreement could not be achieved after a training session. This could either indicate that the short training session was insufficient and further efforts are necessary to develop a training tool, which is able to increase both within- and between-observer agreement, or that the training in the middle confused the participants.

Conclusions: In conclusion, the mobility score achieved high within- and between-observer agreement, when compared with the available

literature, in all professional groups. The short introduction appears to be sufficient for even inexperienced observers to achieve high observer agreement. Consequently, the mobility score seems feasible for on-farm application.

References: Garcia, E., König, K., Allesen-Holm, B.H., Klaas, I.C., Amigo, J.M., Bro, R., Enevoldsen, C. (2015). Experienced and inexperienced observers achieved relatively high within-observer agreement on video mobility scoring of dairy cows. *Journal of Dairy Science* 98:4560-4571.

Use Of Extended Characteristics Of Locomotor Behavior For Automated Identification Of Lamé Dairy Cows

Gian Beer¹ Maher Alsaad¹ Alexander Starke² Gertraud Schuepbach-Regula³ Hendrik Müller² Philipp Kohler¹ Adrian Steiner¹

¹Clinic for Ruminants, Vetsuisse-Faculty, University of Berne, 3001 Berne, Switzerland, ²Clinic for Ruminants and Swine, Faculty of Veterinary Medicine, University of Leipzig, 04103 Leipzig, Germany, ³Veterinary Public Health Institute, Vetsuisse-Faculty, University of Berne, 3001 Berne, Switzerland

Objectives: Lameness prevalence in dairy cattle and its impact on animal welfare is high. Thus, systems for automated lameness detection are increasingly important. This study was carried out firstly to detect differences in locomotor and feeding behavior between lame (group L) and non-lame (group C) cows and secondly to create an automatic lameness detection model, using data of the three-dimensional acceleration of the hind limbs and activity of the jaw.

Materials and Methods: Twelve non-lame and 41 lame multiparous German Holstein cows, housed in a commercial loose stall in Germany, were included in the study. They were equipped with two three dimensional accelerometers (RumiWatch®), attached to each hind limb, and one halter with noseband sensor (RumiWatch®) attached to the head. Accelerometers and noseband sensors had previously been validated. The devices recorded data of 3 consecutive days (recording period). Using video recordings, each cow's gait was scored on a 5-point scale before and after the recording period, and the mean value of 3 independent experienced observers was taken as definite gait score. Group C cows were defined as showing a gait score ≤ 2, group L as showing a gait score ≥ 2.5.

For comparison between group L and group C, the T-test, the Aspin-Welch test and the Wilcoxon test and for model creation, logistic regression and receiver operating characteristics (ROC) were used.

Results: Group L had compared to group C significant lower eating and ruminating time, fewer eating chews, ruminating chews and ruminating boluses, longer lying time and lying bout duration, lower standing time, fewer standing and walking bouts, fewer, slower and shorter strides and a lower walking speed (P < 0.0001 – 0.04), whereas ruminating chews per minute and ruminating chews per bolus, as well as walking time and number of lying bouts did not differ between group C and group L (P > 0.09 – 0.8). Using only accelerometer variables, we could create a model with a sensitivity and a specificity of > 90%. Additional use of noseband sensor data did not substantially improve the model.

Conclusions: The results of this study show that the newly developed RumiWatch® accelerometers are able to detect differences in a broad set of behavioral parameters in lame and non-lame cows. Models

respecting two accelerometers variables only, automatically identified lame cows with high accuracy. Additional use of the noseband sensor does not provide substantial improvement in accuracy. Management factors influence the behavior of dairy cows. Thus, a multicenter study is needed, taking into consideration various management conditions.

Plasma Metabolic Profiling Analysis of Dairy Cows with Laminitis based on GC-MS

Yanjuan Li¹ Shuwei Dong¹ Zuoting Yan¹

¹LANZHOU INSTITUTE OF HUSBANDRY AND PHARMACEUTICAL SCIENCES OF CHINESE ACADEMY OF AGRICULTURAL SCIENCES, Lanzhou, China

Objectives: Laminitis is a commonly occurring disease which could cause lameness, threatening dairy cows' welfare and causing the huge economic loss in dairy industry. In order to analyze the metabolic change in dairy cows with laminitis, metabolomics strategy was adopted in this study.

Materials and Methods: 20 plasma samples were collected from cows in the laminitis and healthy groups. Plasma metabolic profiles were obtained by utilizing the gas chromatograph-mass spectrometer (GC-MS) technology. Multivariate statistics including principal component analysis (PCA) and supervised partial least squares-discriminant analysis (PLS-DA) coupled with statistic analysis were conducted to compare the metabolite profiles between the two groups and identify the changed metabolites. Bioinformatics were analyzed to compare the metabolic difference and screen the potential biomarkers in laminitis.

Results: 37 metabolites were identified by GC-MS approach, in which 3 were up-regulated and 34 were down-regulated. By using multivariate statistics analysis and pathways enrichment analysis, we found diverse compounds with very significantly different (p < 0.01) pathways including fatty acid biosynthesis, Gly, Ser, Thr metabolism and biosynthesis of unsaturated fatty acids as well as significant differences in the pathways involved purine metabolism, methane metabolism, cyanoamino acid metabolism and phenylalanine metabolism and so on.

Conclusions: Lipid metabolism pathways and Gly, Ser, Thr metabolism pathway play important roles in occurrence and development of laminitis in dairy cows. Our findings reveal the metabolic disorders of laminitis in dairy cattle and provide further knowledge of mechanism and pathogenesis of laminitis.

P03-003-164

METABOLIC AND MINERAL PROFILE IN THE PERIPARTUM: CLAW QUALITY AND CONFORMATION

Fernando P. Casagrande¹ Elias Jorge Facury Filho² Tiago F. Moreira² Priscila Pozzatti¹ Antonio Último Carvalho²

¹Escola de veterinaria, UFBA, Salvador, ²Escola de veterinaria,

Veterinary School of the Federal University of Minas Gerais, Belo Horizonte, Brazil

Objectives: The objectives of this study were to evaluate the variations in conformation measures, endurance, growth and wear of the hooves of dairy cows among the 30 pre-delivery days and 90 days of lactation, as well as changes in the metabolic and mineral profile of dairy cows postpartum period and variations in the occurrence of foot lesions of dairy cows among the 30 pre-delivery days and 90 days of lactation.

Materials and Methods: The research took place at a dairy farm located in Minas Gerais State with a herd with 120 lactating cows, producing 2,000 liters of milk/day. Was used 30 crossbred dairy cows (3/4 Holstein x 1/4 Gyr), between second and fourth calving, assessed between February and August 2012, in which were measured claw conformation, claw hardness, claw growth and wear and the occurrence of foot lesions at 30 days antepartum, at delivery, and at 30, 60 and 90 days of lactation. We took blood samples by puncture of the coccygeal vein weekly during the prepartum beginning in the fourth week before calving expected date, one sampling 24 hours after calving, and in the second, fifth, 10th, 15th, 21th and 30th days postpartum. Thereafter, we conducted analyses of triglycerides, cholesterol, glucose, gamma-glutamyl transferase (GGT), lactate dehydrogenase (LDH), aspartate aminotransferase (AST), non-esterified fatty acids (NEFA) and beta-hydroxybutyrate (BHB) using the technique of spectrophotometry in automatic device and commercial kits. We used cutoff points of 1.2 mmol/L of BHB for subclinical cetose diagnose and below of 8.5mg/dl in postpartum for subclinical hipocalcemia. Was evaluated the changes in the energetic and mineral profiles at 5 and 10 days postpartum and their correlation with claw conformation, claw hardness, claw growth and wear and the occurrence of foot lesions.

Results: Was observed increase in the claw angle and heel depth and decrease of dorsal wall length between the 30 days' pre-partum and 90 days of lactation. The hardness of the claw decreased at day 30 of lactation in the measurements done on the wall and the sole-wall. In the white line and sole the hardness decreased at birth and at 30 days of lactation. The claw growth rate reduced and claw wear increased in the first month of lactation. Were identified correlations between the concentrations of calcium, phosphorus, magnesium and non-esterified fatty acids (NEFA) at postpartum and claw measurements evaluated in the first three months of lactation. Low concentrations of serum calcium were correlated with lower claw growth rate and the lower claw hardness. Low magnesium concentrations were correlated with higher claw wear rate. High NEFA concentrations presented correlation with lower claw hardness. The frequencies of digital dermatitis were 60%, 63%, 73%, 53% and 46%, respectively at 30 days antepartum, at delivery, and at 30, 60 and 90 days of lactation. The frequencies of interdigital dermatitis were 46%, 36%, 53%, 46% and 46%, respectively at 30 days antepartum, at delivery, and at 30, 60 and 90 days of lactation. The frequencies of bleeding soles were 13%, 16%, 26%, 40% and 60%, respectively at 30 days antepartum, at delivery, and at 30, 60 and 90 days of lactation. And the frequencies of white line disease were 10%, 33%, 33%, 36% and 46%, respectively at 30 days antepartum, at delivery, and at 30, 60 and 90 days of lactation.

Conclusions: Claw conformation, hardness, growth and wear and the frequencies of claw lesions were influenced by mineral and metabolic alterations in the transition period. Subclinical hipocalcemia and cetose can alter the health of hoof in cows during the early lactation.

P03-003-165

The effects of lameness on reproductive parameters and milk production in dairy cows

Kiro Petrovski¹, Rebecca Wood¹, Richard Laven²

¹The University of Adelaide, Roseworthy, Australia, ²IVABS, Massey University, Palmerston North, New Zealand

Objectives: The main objective of this study was to estimate the effect of lameness on some reproductive parameters and milk production in dairy cows using monthly locomotion scores as an indicator for lameness. Optimum reproductive performance is crucial for milk production. Lameness has the potential to affect fertility at all stages of reproduction. Explanations include changes in oestrus behaviour due to lameness (e.g. less willing to be mounted due to pain related stress and uneven bearing of weight) and sore limbs and hooves. Other explanations could include diminished appetite, reduced conception rates and weight loss.

Materials and Methods: Farms Services at Massey University, New Zealand, supplied the data for this study. During on farm herd tests, data were collected, including monthly locomotion scores 0 - 3 scale (0 and 1 non lame, 2 and 3 lame) and mating records from two dairy farms over 24 months. The management systems of the two farms were a spring calving system with 450 cows, and a split calving system with 230 cows.

Data were analysed using Statistical Analysis Software (SAS) version 9.3. The herd data was segregated into three categories based on age: young cows of 2 years of age (referred to as heifers), 3/4 year olds, and cows older than 4 years.

The effects of lameness on various reproductive parameters and milk production were analysed using regression analysis and analysis of variance (ANOVA). For the regression analysis, lame cows were scored as one and non-lame scored as zero. Fixed factors included age, farm and month of mating. The effect of individual cows was included as a random factor. Modelling was carried out using the GLIMMIX procedure. The effects of lameness on reproductive parameters, before and following mating, were tested using analysis of variance in the MIXED procedure. The analysis of variance was also used to estimate the differences between: milk yield, days open, days to first service, number of services per conception and inter-calving interval among cows for each age category.

[LR1]0-3 scale (0 and one not lame, 2 and 3 lame)

Results: The effect of lameness on days open, number of services and days to first mating was inconsistent. The difference in days open of 92 days between lame and non-lame cows in 'before mating 2011', and a difference of 19 days between lame and non-lame cows 'following mating 2011' ($p < 0.05$). The difference of 20 days 'before mating 2012' and 8 days 'following mating 2012' for lame and non-lame cows ($p < 0.05$). A difference of 0.2 services was found between lame and non-lame cows 'before mating 2012', and a difference of 1.3 services between these cows 'following mating 2012' ($p < 0.05$). Regarding days to first service, a difference of 11 days 'before mating 2012' and 3 days 'following mating 2012' was found between lame and non-lame cows ($p < 0.05$).

All age categories displayed a 'normal' left skewed lactation curve with an increase in early lactation until 50 days, followed by gradual decline thereafter. The heifers consistently had the lowest average 305-day milk production (4705.4 ± 25.36 and 4941.4 ± 64.19 L) followed by cows aged 3/4 years old (5396.1 ± 24.17 and 5934.7 ± 41.80 L). Highest milk yields were recorded for older than 4 years cows (5986.7 ± 24.85 and 6447.9 ± 38.44 L for split and spring calving groups).

In 2011, heifers produced a greater total milk yield when lame (5058.2 ± 40.89 and 5022.0 ± 23.27 in lame and non-lame group respectively).

In contrast, in 2012, heifers produced a greater milk yield when non-lame (4975.4± 13.78 and 5006.9± 12.73 in lame and non-lame group respectively). Cows of 3/4 years produced more milk when non-lame.

Conclusions: This study could estimate the impact of lameness on milk production and fertility but one of the key costs of lameness (increased risk of culling due to reasons other than fertility) could not be measured. Results of this preliminary study were inconclusive, thus lameness may or may not have a significant effect on reproductive parameters and milk production. Overall, this study did show that lameness causes significant negative effects on the number of inseminations required for a cow to conceive and days open.

P03-003-166

The risks and economic impacts of Traumatic Recumbency in 233 UK Dairy Herds

Peter Orpin^{1,2} Richard J. Sibley³

¹Park Vet Group, Leicester, ²Special Lecturer, Nottingham University, Nottingham, ³Westridge Veterinary Group, Witheridge, Tiverton, United Kingdom

Objectives: A series on farm meetings were conducted on 26 farms in the UK focusing on reduction of emergency culling as part of a carbon reduction project funded by Arla Foods and facilitated by Kite Consulting. The farmers highlighted traumatic recumbency as a major source of economic loss with a highly variable incidence between farms. The objective was to highlight the incidence and major contributing reasons of traumatic recumbency.

Materials and Methods: The survey was a non-random survey of the participating herds. Attendance to the meeting was voluntary and herds with a higher incidence of emergency culling may have attended. Data was gathered from 234 herds (44,451 cows, average herd size 192) using a questionnaire during the meeting. The data was based on the farmers recollection on "slip" rate (the estimated proportion of cows where their body contacted the ground every week) and the estimated proportion of the cows culled due to traumatic recumbency per year ("splints"), stuck in cubicles and other traumatic reasons. The farmers were also asked to identify the high-risk areas and cow risk factors for traumatic recumbency. The cumulative results were discussed with the farmers as the programme progressed. Due to the traumatic nature of the events the farmers were able to readily recollect the estimated number.

Results: Median culling rates for traumatic recumbency were 1.0% (range 0-6.3% Q1, 0.6%, Q3 1.9%). The median slip rate (% herd falling where body or udder touches the ground per year) was 52% (ranges 0-543%, Q1, 23% Q3, 93%). The top 3 cow risk reasons for recumbency were freshly calved, oestrus behaviour and calving problems. The top 3 risk areas were un-grooved concrete, congestion points and sloping areas. The farmers were broadly unaware of the variation between farms and accepted their own incidence as normal. The vet was seldom involved in discussions on how to reduce the incidence. The economic impact was discussed and this prompted the farmers to take action to reduce the incidence using a variety of techniques. A number of the farmers discussed how heat expression was difficult and it is possible that the economic impact of the type floor surface may have additional impacts on fertility and udder health.

The estimated profit opportunity from reducing traumatic recumbency from bottom quartile to top quartile was 0.61 pence per litre equating to a

herd benefit of £9,081 for the average herd based on culling costs alone. This is likely to be an underestimate of the true cost.

Conclusions: Reducing traumatic recumbency should be prioritised within farmer extension programs and more research is required to identify the correct combination of grooving and flooring surfaces in UK dairy herds to optimise cow welfare. Farms with incidences of traumatic recumbency above 0.5% (1 in 200 cows) per year should be provided with practical advice on how to reduce the incidence. The collection and discussion of the farmers' data was a highly effective method of highlighting the profit opportunity of reducing traumatic emergency culls.

P03-003-167

Impact of oral meloxicam administered alone or in combination with gabapentin on experimentally-induced lameness in beef calves

Hans Coetzee¹ Ruby Mosher² David Anderson³ Ronette Gehring⁴ Butch KuKanich⁴ Brad White² Chong Wang⁵

¹Department of Veterinary Diagnostic and Production Animal Medicine, Iowa State University, Ames, Iowa, ²Department of Clinical Sciences, Kansas State University, Manhattan, KS, ³Large Animal Clinical Sciences, University of Tennessee, Knoxville, Tennessee, ⁴Department of Anatomy and Physiology, Kansas State University, Manhattan, KS, ⁵Department of Statistics, Iowa State University, Ames, Iowa, United States

Objectives: Lameness is one of the most important welfare challenges in livestock production and is considered a chronic pain syndrome because hyperalgesia persists for at least 28 d after the causal lesion has resolved. Gabapentin is a γ -aminobutyric acid (GABA) analogue used extensively for the management of chronic pain in humans. Meloxicam (MEL) is a NSAID that is approved as an adjunctive therapy of acute respiratory disease, diarrhea and acute mastitis. This study examined the pharmacokinetics and analgesic effect of oral meloxicam (MEL) administered alone or in combination with gabapentin (GABA) in an experimental bovine lameness model.

Materials and Methods: Eighteen male British \times Continental beef calves aged 4 to 6 mo and weighing 297 to 392 kg were randomly assigned to receive either (1) 0.5 mg/kg lactose monohydrate placebo (PLBO) (n=6); (2) 0.5 mg/kg MEL (n=6); or (3) 0.5 mg/kg MEL combined with 15 mg/kg GABA (MEL-GABA) (n=6) q24h for 4 d. The first treatment was administered 4 h after a chemical synovitis/arthritis was induced with injection of 15 mg amphotericin B into the left hind lateral distal interphalangeal joint. Changes in activity were evaluated continuously with pedometers. Contact force, contact area, contact pressure, impulse and stride length were recorded once daily with a pressure mat and visual lameness scores were determined by a masked observer using a 5-point scale. Cortisol and drug concentrations were determined daily by immunoassay and HPLC-mass spectrometry respectively. Outcomes were compared statistically using a random effects-mixed model and ANCOVA.

Results: There was a positive association between lameness scores and serum cortisol concentrations (P = 0.02) and a negative association between lameness score and step count (P < 0.0001), total force (P = 0.001), force applied to the lateral claw (P = 0.02), contact pressure (P = 0.005) and impulse of the lateral claw (P = 0.01). Step count was greater in MEL calves compared with PLBO (P = 0.008) and MEL-GABA (P = 0.04) calves. Impulse was greater in the MEL-GABA calves compared

with the PLBO calves ($P = 0.03$). There was an inverse relationship between plasma MEL concentrations and lameness score ($P = 0.02$) and a positive association between MEL concentrations and force applied to the lateral claw ($P = 0.03$), total contact pressure ($P = 0.03$) and impulse on the lateral claw ($P = 0.02$). There was a tendency towards a positive association between GABA concentrations, total impulse and impulse on the lateral claw ($P = 0.08$) and a negative association between GABA concentrations and step count ($P = 0.08$).

Conclusions: The results of this study suggest that MEL administered alone or in combination with GABA reduced the severity of lameness in calves following induction of lameness with amphotericin B. These findings have implications for developing analgesic protocols in lame calves that address both production and welfare concerns.

Lameness

P03-003-168

Dyskeratosis and laminar distortions development assessed by sequential hoof biopsies in beef cattle subjected to a high-grain diet on feedlot

Alvaro D. P. L. Oliveira¹, Daniel Ottoni², Diogo G. Jayme², Fabiano A. Barbosa², Cahue F. R. Paz¹, Steffany O. Barbosa¹, Heloisa M. F. Mendes¹, Rafael R. Faleiros¹

¹Clinica e Cirurgia Veterinarias, ²Zootecnia, Universidade Federal de Minas Gerais, Belo Horizonte.MG, Brazil

Objectives: The objective was to describe histological characteristics and to measure the epidermal laminae length of the bovine laminar tissue assessed by sequential hoof biopsies before and after high-grain diet on feedlot.

Materials and Methods: 11 Nelore bulls (20 months old, mean weight of 295kg) were housed on feedlot (16 m²/head) for a period of 100 days. The diet contained grass silage (23%) and grain (77%) and was calculated in order to provide a daily weight gain of 1.3kg. Hoof biopsies were taken one week before and at the end of the feeding period with each bull restrained in stock and under perineural anesthesia of the distal left hind limb. After hoof scrubbing, a circular saw mounted in a rotary tool was used to create a rectangular defect (3 x 0.5 cm) parallel and 3 cm distal to the coronary band of the lateral claw. A specific tool named Falcão-Faleiros lamelotome was used to collect hoof the laminar biopsies. At the end of the feeding period, another fragment was taken at the same level from the new cornified tissue that grew from the coronary band pushing the hoof defect distad. Tissue samples were routinely processed for histology and stained with H&E and PAS.

Results: Laminar histological pattern was considered normal in all baseline samples. The mean (\pm SD) length of epidermal laminae was $1449 \pm 338\mu\text{m}$. In contrast, all biopsies taken at the end of the experiment were abnormal showing apoptosis and distortion. The length of epidermal laminae ($252.3 \pm 66.2\text{ mM}$) was reduced ($P < 0.001$) compared with baseline values. An abnormal dyskeratotic layer ($287.9 \pm 85.3\ \mu\text{m}$ of thickness) was observed abaxial to the stratum laminar in all samples. These findings are compatible with hoof capsule distortions commonly seen in cases of subclinical laminitis.

Conclusions: In conclusion, the use of sequential hoof biopsies brought new information about the development of hoof lesions compatible with subclinical laminitis in cattle subjected to a high-grain diet on feedlot.

Lameness

P03-003-169

A retrospective analysis of field data to investigate the prevalence of foot lesions in dairy cows in the South West of England. A comparison from 2008 to 2015

Jon Reader¹, Mark Burnell¹ on behalf of Cattle Lameness Academy

¹Cattle Lameness Academy / Synergy Farm Health, Evershot, United Kingdom

Objectives: The recording of both incidence and prevalence of lameness of the bovine on a farm level is poor across the world with a limited ability to meaningfully collate data across multiple herds as well as relying on repeatable lameness nomenclature and recording system. This study retrospectively analyses the data from a large veterinary practice in the South West of England employing 7 trained veterinary-led foot trimmers. The study also compares the most recent lesion prevalence with similar analyses performed in both 2008/9 and 2012 to the results from 2014/5.

Materials and Methods: Seven qualified foot trimmers (certified to a Dutch Diploma or NPTC Level 3) were equipped with bespoke technology to record lesions from foot trimming sessions on farm at the zonal level on the cows foot. The trimmers met regularly to standardise both nomenclature as well as trimming technique. The records from all sessions were analysed to investigate the prevalence of the major foot lesions recorded by the foot trimmers. These results were then also compared with two similar prevalence summaries carried by the same authors in 2008/9 (UK Cattle Lameness Conference) and again in 2012 (International Cattle Conference, Bristol).

Results: For the 12 months to the end of October 2015, 1131 trimming sessions were carried out on 146 farms. 23,792 cows were presented for foot trimming of which 17,038 had all four feet examined. Lesions were recorded on 13,101 (55%).

Bruising of the sole was the most recorded 'lesion' on the foot. However, excluding bruising, the predominant lesions that are recognised to cause lameness in cattle were White Line disease (22%, Digital dermatitis (22%) and Sole Ulceration (15%). Claw horn lesions believed to be associated with treponemes such as Toe necrosis and other so called 'non healing' lesions accounted for 8% of the lesions. Following further training the recording of sole fracture has risen to 3% of all lesions. A comparison is also made to data from other areas in the world.

Conclusions: The three main lesions recorded by foot trimmers in this part of the South West of England remain White Line Disease, Digital Dermatitis and Sole Ulceration. The herds trimmed by the team tend to be those that regularly foot bath their animals and so as in previous reports it is worth noting that there may be a selection bias on this prevalence data which gives an apparent low prevalence of digital dermatitis. The study continues to demonstrate the difficulties in recording consistent, reliable quality data in the this field.

Impact of lameness on productive and reproductive performance of grazing dairy cows

Joaquin Chiozza-Logroño^{1,2}, Santiago Corva³, Ramiro Rearte³, German A. Dominguez¹, Laura V. Madoz^{1,2}, Mauricio J. Giuliodori⁴, Rodolfo L. De La Sota^{1,2,*}

¹Catedra y Servicio de Reproduccion Animal, Facultad de Ciencias Veterinarias, Universidad Nacional de La Plata, La Plata, B1900AVW. Buenos Aires, ²CONICET, Godoy Cruz 2290. CABA. C1425FQB, ³Curso de Bioestadística, Facultad de Ciencias Veterinarias, Universidad Nacional de La Plata, La Plata. B1900AVW. Buenos Aires, ⁴Catedra de Fisiología, Facultad de Ciencias Veterinarias, Universidad Nacional de La Plata, La Plata, B1900AVW. Buenos Aires, Argentina

Objectives: The objective of this study was to access the impact of timing of lameness case occurrence on milk production and reproductive performance in grazing dairy cows. The objective of this study was to access the impact of timing of lameness case occurrence on milk production and reproductive performance in grazing dairy cows.

Materials and Methods: A five-year retrospective longitudinal study was conducted in one commercial dairy farm in Argentina (35°37' S, 61°22' W). Cow records (n= 11,061) from cows that calved and were dried off between January 2010 and December 2014 were retrospectively divided into four groups according to time in lactation when the first lameness case was reported: healthy cows (G0), first lameness case prior to first postpartum AI (G1), first lameness case between first postpartum AI and pregnancy diagnosis (G2), and first lameness case after diagnosed pregnant (G3). Non-lame (G0) and lame cows (G1-G3) did not have any other concurrent disease at the same time during lactation (uterine infections, anovulatory conditions, and mastitis). The lameness effect on milk production at 150 DIM (MP150), at 305 DIM (MP305), and on interval from calving to first AI (IC1AI) and from calving to conception (ICC) were evaluated. In addition, the lameness effect on the risk for being inseminated by 80 days in milk (DIM, [AI80]), pregnant by 100 DIM (PR100), and open by 200 DIM (OP200) were evaluated. The statistical models included the fixed effect of Group (0 through 3), year (2010-2014), season of parturition (spring, summer, fall, and winter), parity (1, 2, 3+), and their second-order interactions. Modeling was performed using a manual backward elimination method with an exclusion criteria set at P > 0.2. The GLIMMIX, PHREG and LIFETEST procedures of SAS were used.

Results: Milk production 150 and MP305 were 116 and 181 kg higher in G0 compared to G1 cows (5152±23 vs. 5036±43, P=0.023; 9876±53 vs. 9695±91; P=0.074), but there was no difference in MP150 and MP305 in G0 regarded to G2 and G3 cows. The G0 cows had 6 to 12.5 days shorter IC1AI compared to G1, G2 and G3 cows (67 vs. 79.5 vs. 73 vs. 75, P<0.001). The G0 cows had 30 to 62 days shorter ICC compared to G1, G2 and G3 cows (96 vs. 126 vs. 158 vs. 127, P<0.001). The risk for AI80 was affected by Group since the odds ratio (OR) were 0.34 (0.26-0.44) for G1, 0.59 (0.47-0.74) for G2, and 0.48 (0.40-0.57) for G3 compared to G0 cows (P<0.001). The risk for PR100 was also affected by Group since the odds ratio (OR) were 0.47 (0.40-0.61) for G1, 0.37 (0.30-0.46) for G2, and 0.68 (0.57-0.80) for G3 compared to G0 cows (P<0.001). The risk for OP200 was affected by Group since the odds ratio (OR) were 1.58 (1.23-2.04) for G1, 1.46 (1.18-1.81) for G2, and 0.95 (0.79-1.14) for G3 compared to G0 cows (P<0.001). Finally, the median days to conception were 96 for G0 cows, whereas they were 126, 158 and 128 for G1, G2 and G3 cows (P<0.001). Conversely, Group had no effect on the hazard ratios (HR) for pregnancy (P=0.801) given that the HR were 0.90 (0.66-1.22) for G1, 0.83 (0.67-1.03) for G2, and 0.93 (0.76-1.14) for G3 cows.

Conclusions: Lame cows have lower milk yield and take longer to get pregnant. In addition, the time at which the cow become lame is important given that its negative impact on both, milk production and reproductive performance, is greater when it occurs before conception in early lactation. In conclusion, cows diagnosed as lame in early lactation have worst productive and reproductive performance than non-lame herdmates under grazing conditions.

Comments: This study was supported in part by UNLP grant V11/200 and V11/230 to RL de la Sota. In addition, J Chiozza-Logroño was supported with a scholarship from CONICET.

Recently emerged clinical pattern of arthritis and mastitis associated with *Mycoplasma bovis* in Irish dairy cows

William Byrne ^{1,*} Jane O'Rourke ¹ William Fitzgerald ² Tom Kent ³ Damien Barrett ⁴

¹Department of Agriculture, Food and the Marine (DAFM) Laboratories, Backweston Campus, Celbridge, Co. Kildare, ²Kilkenny Regional Veterinary Laboratory, DAFM, Kilkenny, ³Suirside Veterinary Clinic, Carrick on Suir, Co. Tipperary, ⁴Regional Veterinary Laboratory, DAFM, Sligo, Ireland

Objectives: Respiratory disease is the most common clinical presentation of *Mycoplasma* (M) *bovis* infection in Irish cattle. Cases of arthritis have also occurred sporadically, predominantly in calves, young cattle or housed beef fattening cattle, often as a sequel to respiratory disease. Until 2013, arthritis or mastitis caused by M *bovis* were rarely diagnosed in Irish dairy cows. In 2013 and 2014, arthritis and/or mastitis cases, associated with M *bovis* in dairy cows occurred in 17 Irish herds. The objective was to describe the clinical pattern observed, diagnosis and control measures applied.

Materials and Methods: Samples of aseptically collected joint fluid or milk samples were subjected to microaerophilic culture on mycoplasma broth and agar plates and to polymerase chain reaction for M *bovis* (Sachse et al, 2010). Further information about the clinical presentation, number of cows similarly affected, time affected, their response to treatment and their outcome was sought by questionnaire survey and herd investigation visits by the authors. Also, the extent of mycoplasma mastitis in the affected herds was determined by testing of milk samples from other cows. Cows detected with mastitis were segregated and milked last as part of a mastitis control programme.

Results: During the first four months of 2013 and 2014, a range of 2 to 28 dairy cows per herd presented with lameness, reduced flexibility and swelling of one or more joints, in 13 seasonal spring-calving, dairy herds. In each of these herds, cases of swollen joints occurred within three to seven weeks of the occurrence of its first clinical case. The severity of lameness varied. Most cases were refractory to treatment initially. The metacarpophalangeal joint (fetlock of forelimb) was the most frequently affected joint, but also the carpus, hock and metatarsophalangeal joint in other cases. M *bovis* arthritis was diagnosed by isolation of mycoplasma colonies and by polymerase chain reaction, from samples of joint fluid from one or more cows in 12 of those herds and from milk samples from cows in the 13th herd. Mycoplasma arthritis occurred as a primary clinical presentation without any clinical signs of respiratory disease in the majority of the affected cows. Cases of M *bovis* mastitis were diagnosed, mostly in cows that were not affected by lameness, in 5 of those 13 herds. Mycoplasma mastitis was diagnosed in cows in 4 further dairy herds for which no cases of arthritis were reported during 2013 and 2014. In some herds M *bovis* was also isolated from cases of arthritis or respiratory disease in calves. For each herd partaking in a mastitis control program, a cessation of occurrence of new cases of mycoplasma mastitis occurred. Mycoplasma mastitis was eliminated from herds, from which these cows were culled.

Conclusions: *Mycoplasma bovis* arthritis and mastitis were diagnosed in adult dairy cows in Ireland in a series of herd outbreaks affecting 17 dairy herds in the years 2013 and 2014. Control programs were applied to contain the extent of (and/or to eliminate) mycoplasma mastitis from affected herds.

Atlas Of Infectious Hoof Diseases For Practicing Veterinarians

Miia Kontturi¹ Reijo Junni¹ Heli Simojoki¹ Minna Kujala¹ Erja Malinen² Eija Seuna² Sinikka Pelkonen² Timo Soveri¹

¹Faculty of Veterinary Medicine/ Production Animal Medicine, University of Helsinki, ²Evira, Finnish Food Safety Authority, Helsinki, Finland

Objectives: Currently infectious hoof diseases are an emerging problem in Finland. Various diseases and their similarity in different stages of the disease, thus somewhat different treatment and prognosis can be puzzling. In some cases, incorrect diagnosis can lead to unnecessary antibiotic or other treatments. Therefore, to make a clinical diagnosis as correct as possible is crucial to practitioners, hoof trimmers and farmers.

Materials and Methods: During 2012 – 2015, a research project of infectious hoof diseases existed in Finland. Within this project 28 farms visits were made and 245 cows (287 hooves) inspected in case of infectious hoof diseases. Cows were included to the study based on suspicion of infectious hoof diseases. The main interest was interdigital phlegmon and whether the lesion was acute, healing or chronic. Additionally, digital dermatitis (DD), interdigital dermatitis (ID), heel horn erosion and interdigital hyperplasia were detected. All the inspected hooves were photographed for a more precise analysis of the disease. Four veterinarians, who were experienced in infectious hoof diseases, together made the final diagnosis of the hooves from the photos.

Results: From the various photographs a color atlas of infectious hoof diseases was established. Pictures of healthy hooves were also included. The atlas can be found for free in the webpages of Animal Health ETT <http://www.ett.fi/sisalto/sorkkaterveys>.

Altogether 287 feet were photographed. Interdigital phlegmon was detected in 133 feet of which acute 26.8% (77/287), healing 19.2% (55/287) and chronic 0.35% (1/287). ID and DD was detected less frequently 14.3% (41/287) and 18.5% (53/287) respectively, as well as interdigital hyperplasia 6.0% (17/287). On the contrary, heel horn erosion was detected in 88.5 % of the inspected feet (254/287). Only 4.5% (13/287) of selected hooves were considered healthy of infectious hoof diseases.

Conclusions: Difficulties in diagnosis making process were apparent. Occasionally, the anamnesis of the cow and the information about an antibiotic treatment were necessary to differentiate the healing process of an interdigital phlegmon from an acute lesion of DD. Altogether, many cows suffered from several infectious hoof diseases simultaneously.

Laminitis lesions in the hooves of the Goats picked up during hoof trimming in a herd of goats

Seifollah Dehghani Nazhvani¹ Mina Tadjalli²

¹veterinary Surgery, ²veterinary Anatomy, school of Veterinary Medicine, Shiraz University, Shiraz, Iran, Islamic Republic Of

Objectives: objectives. The foot of a goat is one of nature's works of art; it is designed such that a goat can easily balance upon rocks and steep crevices with very little trouble. In Iran, goats are mainly raised on pastures and therefore they need foot inspection less frequently. Permanently confined management system requires regular foot trimming schedule once or twice a year depends on the herd conditions. In this survey, hoof morphometric was studied prior and after trimming in goats in different chronic laminitis conditions.

Materials and Methods: A flock of indigenous goats raised indoors were inspected for hoof problems. All the goats were inspected and trimmed if it was necessary. Care was taken not to overtrim or to induce an unwanted ulcer or so. 28 goats weighted 51.25 ± 6.22 kg with abnormal foot condition were trimmed. Fore limbs and hind limbs were trimmed. The dimensions of the hoof such as dorsal hoof wall length and heel height were measured before and after trimming. Any abnormal conditions such as ulcer, crack, over growth etc was recorded

Results: The goat hoof is solid and strong. The ideal cranial wall length after trimming was found to be 3.8 ± 0.4 cm, the heel height was best 2.0 ± 0.2 cm. During hoof trimming, deep grooves in the heel (heel horn erosion), hoof cracks, heel ulcer, toe ulcer, white line disease, curling toe over growth and medial claw heel over expansion (overgrowth) both in fore and hind leg were noticed and recorded. Medial claw heel overgrowth in fore and hind legs was found to be dominant lesions observed in this study (21.4 %).

Conclusions: Chronic laminitis like lesion found in this herd suggested that feeding management as well as heat stress and other stressful conditions could be the major risk factors. Excessive growth of the wall is common especially towards the toe, and excessive growth of the sole was seen, particularly at the heel. An average length of the toe and heel height was proposed as a guide line for hoof trimming routine process. A general rule about trimming goat's feet was that the hoof's hairline (the coronary line) should be almost parallel to the ground. Over-trimming was highly undesirable which cause permanent damage to the feet such as toe granulomas.

P03-003-174

Epidemiologic survey of lameness and hoof lesions to establish a control program in Prata city.

Tiago Facury Moreira¹ Rafael R. Nicolino² Antônio U. Carvalho³ Elias J. Facury Filho³ Alonso P. Silva Filho⁴

¹ Department of Veterinary Clinic and Surgery, ²Department of Preventive Veterinary Medicine, ³Department of Veterinary Clinic and Surgery, Federal University of Minas Gerais, Belo Horizonte, ⁴Department of Veterinary Medicine, Universidade Federal Rural de Pernambuco, Recife, Brazil

Objectives: Today hoof lesions and consequently lameness is considered one of the three most common occurrences in dairy cattle and despite the advancement of knowledge its prevalence is increasing over the years. To reduce this prevalence, socioeconomic works are needed. Therefore, this project was developed to determine the prevalence of lameness and hoof lesions and to assess the risk factors present in a representative area of Minas Gerais, Brazil. Furthermore, we want to know the understanding and perception of farmers about lameness for further development of a lameness control program.

Materials and Methods: We visited 48 dairy farms and examined 370 lactating dairy cows in the Prata municipality in Minas Gerais State, Brazil. All farms had a pasture based system with concentrate supplementation and with average daily milk production/ cow between 5 and 19L. In each visit 7 to 12 animals were randomly selected and had the four limbs evaluated. They were contained in a mobile trimming chute and hoof lesions were noted in a sheet. Lameness score of the whole herd were recorded using a scale of 0-3 according to Stokes et al. (2008). The risk factors and preventive actions presented in each farm were also noted using a model form. The animal use for the research was previously authorized by each farmer and this project was approved by the The Ethics Committee on Animal Experimentation of Universidade Federal de Minas Gerais.

During the visit, a semi-structural questionnaire was applied to the owner or farm's manager to know their perceptions about the hoof lesions in the farm. All the interviewees were informed about the purpose of the research and signing by free will a consent form.

Results: Lameness was a great problem in the region with 16.14% of animals being lame and 6.93% being severe lame. Farmers perceived only 64.71% of the lame cows, but, nonetheless, 34% of farmers claimed lameness to be the major problem they have.

Hoof lesions were presented in 97.2% of animals. The lesion with higher prevalence in decrease order was heel erosion (89.80%), white line disease (51.28%), digital dermatitis (DD) (31.12%), sole hemorrhage (26.8%), others (17.8%), overgrown claw (16.58%), parasitic coronitis by *Tunga* spp. (12.24%) and interdigital dermatitis (11.22%). We didn't find animals with sole ulcer.

Analyzing the whole scenario we concluded that the infectious lesions type was the most important, especially DD while laminitis has minor importance. The reasons why these diseases have become so important is the lack of information, biosecurity and preventive measures. The purchase of animals is a common practice and 85.11% of farmers said that they often buy animals without examining them for other disease than for tuberculosis and brucellosis or take other preventive or biosecurity action. Only 6.25% of the farms used foot bath regularly. The way to treat the lesions was another important issue with 35.42% of farmers using systemic antibiotic and 27.08% saying that they used to do interventions but most often by a non-trained person.

The major obstacles reported by producers to reduce the lameness prevalence or to treat animals was lack of adequate facilities like a trimming chute, lack of trained professionals and lack of information.

Conclusions: Lameness is a great problem in the region and it is mainly caused by digital dermatitis. There are a large number of farmers that perceived lameness to be one of the greatest problems they face. They consider that the lack of proper facilities, lack of information and trained professionals are some of the causes. These factors are displayed in the absence of prophylactic and biosecurity actions as well as the improper treatment provided to animals.

To reduce lameness prevalence in the region is necessary to do a work with the objective to raise awareness and facilitate access to information of farmers and consultants that work in the region.

Hormonal, metabolic and behavioral stress response to treatment of claw horn lesions

Christian Wunderlich¹, Simone Janßen¹, Maike Heppelmann¹, Rupert Palme², Alexander Starke³, Wolfgang Kehler¹, Adrian Steiner⁴, Awad Rizk⁵, Ulrich Meyer⁶, Sven Dänicke⁶, Jürgen Rehage¹

¹University of Veterinary Medicine Hannover, Clinic for cattle, Hannover, Germany, ²Department of Biomedical Sciences, University of Veterinary Medicine Vienna, Vienna, Austria, ³Department of Large Animal Medicine, Faculty of Veterinary Medicine, University of Leipzig, Leipzig, Germany, ⁴Clinic for Ruminants, Vetsuisse-Faculty, University of Berne, Berne, Switzerland, ⁵Surgery, Anaesthesiology and Radiology Department, Faculty of Veterinary Medicine, Mansoura University, Mansoura, Egypt, ⁶Institute of Animal Nutrition, Friedrich-Loeffler-Institute, Federal Research Institute for Animal Health, Braunschweig, Germany

Objectives: The objective of this blinded, randomized and placebo-controlled study was to evaluate the hormonal, metabolic and behavioral stress response of dairy cows after pre-emptive administration of the nonsteroidal anti-inflammatory drug (NSAID) ketoprofen on the treatment of acute claw horn lesions.

Materials and Methods: Forty-two German Holstein dairy cows of one herd were studied; twenty-one cows (group L) with a lameness score of ≥ 2 (range 0 to 5, bi-weekly lameness scoring of herd) of one hind limb and a claw horn lesion (sole ulcer or white line disease) were enrolled and treated according to a pre-prepared randomization list either with ketoprofen or placebo administered 15 minutes before claw trimming in lateral recumbency (LR). Each lame cow was matched with a healthy control cow (control group; C) from the same herd according to parity and stage of lactation. Control cows were treated with placebo and also received claw trimming on a surgical tipping table. Claw trimming and treatment of claw lesions was performed according to the Dutch school (Toussaint Raven, 2003). The time span for claw trimming in controls was adjusted to claw trimming and treatment of lame partner cows. Blood samples were collected from the jugular vein before treatment, at the end of the period in LR and after 24 h by venipuncture. They were analyzed for cortisol, fatty acids, lactate and glucose. Fecal cortisol metabolites were measured before and 24 h after surgical intervention. Behavior on the surgery table was recorded as vocalization, movements of the treated leg and of the whole body, without differentiating the magnitude of movements. Results were statistically evaluated by ANOVA for repeated measurements and scores by means of Wilcoxon test (SAS package vers. 9.3).

Results: In lame cows mean lameness scores were by about 0.5 score points reduced compared to baseline scores ($p < 0.05$) immediately and also 24 h after surgical intervention. Immediately after surgical treatment concentrations of blood cortisol ($p < 0.05$), fatty acids ($p < 0.05$) and glucose ($p < 0.05$), as well as 24h after treatment of fecal cortisol metabolites ($p < 0.05$) were higher in lame cows than in control cows. Also leg movements during treatment occurred more frequently ($p < 0.05$) in lame cows compared to controls. Neither average vocalization scores during treatments on the surgery table nor strong whole body movements were different between groups. No group differences were found between lame and control cows 24h after treatment for blood levels of cortisol, fatty acids and glucose. Pre-emptive administration of ketoprofen revealed no significant effects on study parameter.

Conclusions: Treatment of claw horn lesions in acute stages as commonly performed by professional claw trimmers without anesthesia and analgesia appears to be painful for affected animals. Results provided no indications for a reduced stress response on claw treatment

by pre-emptive application of the NSAID ketoprofen. In view of animal welfare aspects, adequate pain management appears obligatory while performing any kind of claw treatment. However, more studies are necessary to elucidate the severity of pain associated with treatment of claw horn lesions and on the development of adequate and adjusted pain management protocols for such interventions.

Treatment of long bone, metacarpal and metatarsal fractures in 202 calves and cattle

Melanie Feist¹·Christoph Müller¹·Theresa Tschoner¹·Gabriela Knubben-Schweizer¹

¹Clinic for Ruminants with Ambulatory and Herd Health Services, Center for Clinical Veterinary Medicine, 85764 Oberschleissheim, Germany

Objectives: The description of this study is to compare the causes, location, configuration, treatment and outcome of conservatively and surgically treated long bone fractures in hospitalized cattle during a 10 year period.

Materials and Methods: The medical records and radiographs of all patients which were presented to the Clinic for Ruminants with Ambulatory and Herd Health Services, LMU Munich, between 2003 and 2013, for reasons of long bone fractures and fractures of metacarpal and metatarsal bones were retrospectively analyzed. Information extracted from the medical records included location and classification of the fracture, treatment (i.e. conservative vs. surgical), the documented clinical course, results of radiographic re-examinations, and the final outcome of therapy.

Results: A total of 202 cattle with 208 fractures were included in the study. The location of these fractures was as follows: 7 (3.4%) at the humerus, 12 (5.8%) at radius and/or ulna, 53 (25.5%) at the femur, 30 (14.4%) at the tibia, 61 (29.3%) at the metacarpus and 45 (21.6%) at the metatarsus. The majority (n = 134; 66%) of were less than two weeks of age. A total of 32 animals (16%) were presented between the age of 15 days and one year, while 36 patients (18%) were older than one year. Fractures of metacarpus and metatarsus were most often seen in calves younger than 2 weeks of age. The majority (57%) of the presented fractures were induced during assisted delivery. In 51 patients, no treatment trial was performed for reasons of poor prognosis or financial constraints. In the remaining 153 animals, 88 (57.5%) were treated conservatively and 65 (42.5%) surgically. In the subset of conservatively treated patients 70 out of 88 (79.5%) were treated successfully and showed a full recovery, whereas 33 (50.8%) of the surgically treated patients had a positive outcome. Fractures of the metacarpal or metatarsal bones could be treated conservatively with a cast or walking cast and confinement to a stable. Fractures of the long bones, such as humerus, femur, radius and ulna had to be treated surgically by internal fixation in most of the cases.

Conclusions: The surgical treatment was difficult, expensive and often had a cautious prognosis. Missed colostrums feeding and concurrent diseases like neonatal diarrhea, umbilical infections, bronchopneumonia and septicemia had a significant negative influence on fracture healing in newborn calves. Surgical fixation of newborn bones is more difficult than in older calves or in adult cattle because the structure of the long

bones is soft without a sufficient physical strength for implants. Presently osteosynthesis using locking compression plate technique proved more successful than the use of dynamic compression plates in calves.

Comments: The literature lies with the author.

A National Evaluation of Lameness in Canada: Farmers' estimates of lameness compared to in-stall lameness scoring and locomotion scoring

Stephanie Croyle¹·Cathy Bauman¹·Stephen LeBlanc¹·David Kelton¹

¹Population Medicine, University of Guelph (Ontario Veterinary College), Guelph, Canada

Objectives: Lameness is a significant concern for farmers and consumers. Dairy Farmers of Canada (DFC) has established an Animal Care Assessment (ACA) through a ProAction initiative which assesses lameness using locomotion scoring (LS) and in-stall lameness scoring (SLS) techniques. Studies have explored farmers' estimates of lameness compared to LS, but there are no studies on farmers' estimates in Canada, especially when incorporating SLS. The purpose of this study was to determine the prevalence of lameness on Canadian dairy farms using the prescribed methods listed in the ACA, and to explore farmers' perceived lameness in their herds.

Materials and Methods: Data collected for this project was part of a larger and more comprehensive "National Dairy Study (NDS)." The NDS consisted of two phases. Phase I was comprised of a comprehensive questionnaire, and Phase II consisted of a follow-up farm visit.

Phase I was completed in Spring 2015. Every licenced dairy producer in Canada (just under 12,000) was invited to complete the questionnaire that addressed a range of health and management issues, including lameness. The questionnaire was available electronically, by paper copy, or by phone interview. The survey was reviewed by an advisory committee and piloted.

In Phase II, during the summer of 2015, farms that completed Phase I and agreed to participate in Phase II, were selected based on multiple criteria, including but not limited to provincial representation, participation in milk recording, as well as by convenience. For the lameness portion of the farm visit, which was part of a larger animal-based measures assessment, data were collected to gain insight on the prevalence of lameness. Prior to data collection, 16 farm assessors were trained to assess animal based measures such as hocks, BCS, cleanliness, and lameness. The training incorporated two lameness scoring techniques. The first was the traditional 5 point LS, with an overall assessment of limp (score 3, 4, or 5) or no limp (score 1 or 2). The second technique was the SLS system. The assessors had three days of training to insure repeatability and accuracy for all farms (n=378) assessed across Canada.

Results: Phase I was completed by 1,342 dairy producers (11% response rate). The regional distribution of the respondents was representative of the Canadian dairy farm population. 90% of respondents participated in milk recording. 60% of respondents had tie-stalls type barns, 38% free-stall barns, and 2% had pack barns.

In-stall lameness scoring revealed the mean percentage of lame cows on tie-stall farms (n=156) was 38%, with lameness ranging from 0% to 94%. Tie-stall farmer estimates for percentage of lame cows within

Phase I had a mean estimated prevalence of 8%, with estimates ranging from 5% to 34%.

Locomotion scoring identified that free-stall farms (n=222) had a mean percentage lameness of 26%, with a range of 0% to 100%. Estimates by free-stall farmers for percentage of lame cows within Phase I had a mean estimated prevalence of 8%, ranging between 5% and 23%.

These findings indicate that free-stall based farmers failed to recognize 18% of their lame cows (mild to severe limp), while tie-stall farmers failed to recognize 30% of their lame cows.

Conclusions: It is apparent, that worldwide, prevalence of lameness on farms continues to be underestimated by farmers, and Canada is no exception. It is also apparent that tie-stall farmers tend to have a higher prevalence of lameness within their herds, and tie-stall farmers tend to underestimate lameness even more when compared to free-stall farms

P03-003-178

Case study about Radial nerve palsy during regular hoof trimming on dairy farms

Charlotte Kröger^{1,*}

¹Department of Veterinary Science, Ludwig-Maximilians-Universität, Munich, Germany

Objectives: On modern dairy farms regular hoof trimming is an indispensable requirement. Ever and anon cows suffer from radial nerve palsy after being put through a chute. Only poor literature is available relating to that specific topic. In this case study a multidisciplinary research founded the base for an adaptive treatment regimen in cattle.

Materials and Methods: 3 Simmental and 9 Holstein Friesian cattle, housed in free stall barns or tie stalls, showed weakness up to complete disability to bear weight on a front leg. Literature research revealed a lack of scientifically proven methods of appropriate treatment. By lifting the legs in the chute, muscles, nerves and joints are exposed to abnormal pressure. Both in tilt table chutes and in walk through chutes compression and extending forces can lead to structural damage in the front leg. The different external- and internal conditions (chute, time period, body condition, -size, age of the animal, housing, number of legs lifted at the same time) were compared to predict the most probable damage and establish an appropriate treatment.

Results: The radial nerve innervating among others the flexor muscles at the back of the upper arm and those at the front of the lower arm, winds around the proximal humerus right upon the bone. There is no padding underneath protecting the fragile nerve. Compression and extension during trimming can lead to nerve constricting edema of the surrounding tissue or partial disconnection of the nerve. Analgetic and steroids (e.g. Prednisolon) were injected to reduce pain, swelling and limit secondary damage. Frequent physio therapy helps to maintain muscle strength and showed a positive impact on recovery. This treatment protocol is based on the research experience shared with human-, horse and small animal surgeons. The cows were housed separately on a soft but shallow bedding to prevent decubitus ulceration and facilitate the forward moving of the affected, hanging down front leg. One cow needed a scotch cast bandage in addition to the treatment to support the leg which eventually resulted in complete recovery of the front limb too. Only 2 cows couldn't get back on their feet, due to poor housing conditions and severe additional health issues, and had to be put down. Depending on the continuity of animal supervision by the farmer, the quality of on

farm housing possibilities and the will of the animal to stand up, the cows went back to normal gait and could be reintegrated in the milking herd after an average of 7 days.

Conclusions: In case of a radial nerve palsy following the trimming in a chute, proper treatment and support can lead to full recovery. Excluding causes others than compression or extension of the nerve, dysfunction can be treated successfully. Hence, from an economical perspective the attempt of treating the animal is more reasonable than culling and replacement. Best prevention of radial nerve palsy is the knowledge of the anatomical structures on the front limb and its implementation into the routine of trimming.

P03-003-179

Governmental control of lameness in dairy herds in Denmark

Kaspar Krogh^{1,*}Karsten Madsen¹

¹The Veterinary Task Force, Danish Food and Veterinary Administration, Copenhagen, Denmark

Objectives: Lameness in dairy cows is a painful condition that decreases productivity and is a major welfare problem. Lameness is considered the primary cause for losses due to disease in Danish dairy production. Cows with disorders of the hooves and limbs will usually be subjected to considerable pain and suffering. According to the Danish Animal Welfare Act (DAWA), animals should be treated carefully and protected as well as possible from pain, suffering, fear, disablement and major inconvenience. The objective of the study was to investigate whether the dairy farmers were able to handle cows that were lame to severely lame in accordance with DAWA.

Materials and Methods: Thus DVFA has done a survey during the summer of 2015 in 100 larger Danish herds with lactating dairy cows. The observational study included one visit to every included herd by two trained official veterinarians between June and September 2015. At the visits all lactating cows were scored for lameness according to the Locomotion scoring of Dairy Cattle proposed by Sprecher which includes 5 grades for severity of lameness. The numbers of lame to severely lame cows were recorded and the handling of lame cows by the farmer and/or his veterinarian was assessed by the official veterinarians.

Results: In total 100 herds ranging from 80 to 450 dairy cows was visited. The number of lame to severe lame cows ranged from 0 to 9,6 %.

In 28% of the herds handling of lame cows were deemed incorrect or insufficient. In herds with lame cows that handled these correct the following factors were identified; placement of facilities for sick or lame cows close to milking parlours and/or automatic milking systems, dry og non-slibbery surfaces within the stables as well as close collaboration between farmworkers and the veterinarian on handling of lame cows.

Previous studies in Danish dairy herds have revealed a high percentage (10 – 12 %) of moderate to severely lame cows within the herds.

Conclusions: DVFA have the overall responsibility for carrying out on-farm controls of animal welfare provisions in Denmark. If non-compliances are found, the reaction may be either a warning, an enforcement notice or a report to the police. In this study 28 % of herds were given an enforcement notice and 1 herd were reported to the police for mishandling of lame/severe lame cows.

Studies as the one described enables veterinary authorities to follow occurrence of major welfare problems in modern dairy herds and demonstrate – if repeated – an approach to evaluate whether farmworkers handling of lame cows will improve over time.

P03-003-238

Cortisol - Concentration before, during and after claw treatment in German Holstein cows – Testing of different substrates

Maria Reckardt¹, Hendrik Müller¹, Kathrin Nechanitzky², Adrian Steiner², Jutta Gottschalk³, Almuth Einspanier³, Norbert Mielenz⁴, Alexander Starke¹

¹ Clinic for Ruminants and Swine, Faculty of Veterinary Medicine, University of Leipzig, Germany ² Clinic for Ruminants, Vetsuisse-Faculty, University of Bern, Switzerland ³ Institute of Physiological Chemistry, Faculty of Veterinary Medicine, University of Leipzig, Germany ⁴ Institute for Agriculture and Nutrition, Workgroup Biometry and Agrarian Informatics, Martin-Luther-University, Halle, Germany

Objectives: Measurement of blood cortisol has been widely used as a method to assess the activity of the hypothalamic-pituitary-adrenocortical (HPA) axis in cattle. As non-invasive alternative to blood, cortisol was also measured in milk, saliva, lacrima and their metabolites in faeces.

The objective of the present study was to examine the relationship between changes in cortisol concentrations in different substrates following activation of the hypothalamic-pituitary-adrenocortical axis. The stress model used was claw trimming in a walk in crush.

Materials and methods: The present study was conducted between April 2013 and March 2014. Forty three pluripar German Holstein cows were used (age $4,9 \pm 1,3$ years, milk yield $34,4 \pm 7,2$ kg/day, body weight 626 ± 70 kg).

The concentration of cortisol was measured over a time of ten days, where blood cortisol is seen as gold standard. For repeated blood sampling an indwelling venous catheter was introduced into the left jugular vein. Samples of blood, saliva, lacrima and faeces were taken daily between 08 am – 10 am, excluding day four, at this day the samples were collected between 05 am – 06.30 am. During the daily milking between 1 pm – 2 pm the milk samples were taken.

During claw trimming on day four blood and lacrima samples were taken (minute 0, 15, 25, 30, 40, 60, 80). Faecal samples were measured at minute 480, 540, 600 and 660, respectively. Each time, blood was drawn first from the indwelling catheter and afterwards lacrima samples were taken.

Results: Measuring cortisol in saliva, lacrima and milk and the metabolites in faeces should be a non-invasive method for the widely used blood sampling. Milk sampling is only possible at the daily milking. Normally it is no problem taking faeces without handling the animals, in a dairy farm with about 70 animals per group the unambiguous assignment may be a problem. Without fixation of the animal it is not possible to collect saliva and lacrima.

Cortisol levels measured in the current study are similar to those in the literature. The blood cortisol shows a decrease from day one to day two. This decrease is also shown in lacrima, saliva and faeces. Blood cortisol concentration shows an increase on day five, which is also shown in saliva and faeces. This increase is under the blood cortisol level from

day one. The concentrations from day ten in blood, lacrima, saliva and faeces are under their levels from day one. Milk concentration shows ups and downs, with spikes at day two, four, seven and ten which are always higher than the concentration on day one.

During claw trimming on day four there is an increase in blood cortisol concentration which is also shown in lacrima cortisol.

Conclusions: In this study lacrima, saliva and faeces show the blood cortisol trend on some days. Only milk collection during milking is possible without handling the animals more as you need for a blood sampling. In conclusion, none of the tested body fluids caused less stress than drawing blood from an indwelling jugular catheter.

Suitability of BVD antibody ‘spot testing’ in Irish beef herds as a means of annual surveillance.

Riona Sayers¹·Jose M. Lozano²·Padraig O’Sullivan³·Noel Byrne¹·David A. Graham⁴

¹Animal & Biosciences, Teagasc, Moorepark, Fermoy, Co. Cork, ²Virology, Department of Agriculture, Food, and the Marine, Backweston, Celbridge, Co. Kildare, ³Irish Cattle Breeding Federation, Highfield House, Shinagh, Bandon, Co. Cork, ⁴Animal Health Ireland, 4-5 The Archways, Carrick-on-Shannon, Co. Leitrim, Ireland

Objectives: Virus testing of a herd, tissue-tag testing of calves, bulk milk antibody testing, and ‘spot-testing’ of youngstock can be used to determine the bovine viral diarrhoea (BVD) status of a herd. ‘Spot-testing’ involves serological testing of 5-10 homeborn, unvaccinated juveniles over 9 months of age. Positive antibody readings in this herd sub-sample can be indicative of BVD persistently infected animals (a PI herd). The objective of the current study was to investigate the usefulness of ‘spot-testing’ as a means of BVD surveillance in beef herds, following completion of the tag-testing phase of the Irish BVD eradication scheme.

Materials and Methods: Blood samples were collected from BVD unvaccinated youngstock in 146 beef farms nationally between November 2014 and February 2015. It was planned to collect a minimum of five samples from weanlings between 9 and 18 months of age, although this was not achievable in all cases. Serum samples were subsequently tested using a BVD virus total antibody ELISA (IDEXX, USA). Samples with an S/P value greater than or equal to 0.3 were classified as positive. Inconclusive results were classified as negative (n=18). The date of birth of each animal sampled and the number (if any) of PI calves born in a herd in 2014, was downloaded from the Irish Cattle Breeding Federation (ICBF) database.

Initially, a herd recording at least one seropositive animal was deemed ‘spot-test’ positive. Data were then reviewed to remove any ‘spot-test’ positive herds that did not meet sampling criteria (i.e. not all youngstock were homeborn or were under or overage) and the dataset reanalysed (‘edt-spot-test’). Finally, a re-classification (‘reclass-spot-test’) was also applied to the edited dataset which categorised herds as ‘spot-test’ positive only if more than one seropositive individual was recorded. Receiver operating characteristics (ROC) analysis was completed using ‘spot-test’, ‘edt-spot-test’, and ‘reclass-spot-test’ datasets in Stata (Version 12, USA). This enabled the usefulness of ‘spot-testing’ in late 2014/early 2015 to identify a PI herd in 2014. For this analysis, birth of at least one PI was the reference variable and ‘spot-testing’ the classification variable.

Results: Of the 146 herds sampled, 94 were ‘spot-test’ negative and did not record a PI birth in 2014. A total of 37 herds were ‘spot-test’ positive and did not record a PI birth, and two ‘spot-test’ negative herds recorded a PI birth. Thirteen herds were ‘spot-test’ positive and generated a PI in 2014. Following dataset edits, 26 herds were excluded (‘edt-spot-test’). Finally, eight herds containing only a single seropositive in ‘edt-spot-test’ were reclassified as negative herds. ROC results for each dataset are included in Table 1.

Table 1. ROC analysis including measures of sensitivity and specificity of ‘spot-testing’ in identifying BVD PI herds.

Category	AUC (95% CI)	Sensitivity	Specificity
‘Spot-test’	0.7921(0.6950, 0.8892)	86.7%	71.8%
‘Edt-spot-test’	0.8565 (0.7421, 0.9708)	83.3%	87.9%

‘Reclass-spot-test’	0.8919 (0.7798, 1.0000)	83.3%	95.1%
---------------------	-------------------------	-------	-------

AUC = Area under the curve.

95% CI = 95% confidence interval

Conclusions: If sampling criteria are strictly adhered to, ‘spot-testing’ provides a useful means of identifying beef herds in which a BVD PI has been born. If introduced as a surveillance method, therefore, it is essential to inform sampling personnel of the importance of sampling individuals of the correct age. Specificity of this surveillance method can be improved, without impacting sensitivity, by classifying herds as ‘spot-test’ positive only if two or more seropositives are detected.

P04-004-050

Development of Beef HealthCheck – a system for capturing abattoir data on liver and lung lesions in Ireland

R. Carroll¹·J. O’Flaherty¹·A. Forbes²·M. Lynch³·J. McClure³·D.A. Graham¹

¹Animal Health Ireland, Carrick-on-Shannon, Co. Leitrim, Ireland, ²School of Veterinary Medicine, Glasgow University, Glasgow, United Kingdom, ³Irish Cattle Breeders Federation, Bandon, Co. Cork, Ireland

Objectives: Animal Health Ireland (AHI) is a not for profit organisation tasked with pursuing control strategies for economically important diseases of cattle which are not subject to international regulation. In 2015, AHI launched the Beef HealthCheck programme with the aims of developing tools to assist farmers and their veterinary practitioners to control losses due to liver fluke and pneumonia through capture, analysis and reporting of abattoir data and the development by the Irish Cattle Breeding Federation (ICBF) of economic breeding indices that incorporate health and disease data.

Materials and Methods: Beef HealthCheck is an AHI-led programme that has been developed in collaboration with Meat Industry Ireland (MII), ICBF, Veterinary Ireland and the Department of Agriculture, Food and the Marine (DAFM). A standardised Beef HealthCheck scoring system for liver and lung lesions was developed following consultation with AHI’s Technical Working Group on Parasite Control, the DAFM and a review of the literature. AHI has developed material for Temporary Veterinary Inspectors (TVIs), outlining the Beef HealthCheck programme and giving a detailed description of the lesion categories. This material is used as the basis for information meetings for TVIs in each meat factory prior to the roll out of the project. Beef HealthCheck uses touchscreen technology to allow TVIs, who carry out post mortem inspections in Irish meat factories, to record their findings on liver, lungs and where factory layout permits, pregnancies. The data is then transmitted from the meat factory to the ICBF database. Standardised reports for farmers on each batch of animals presented to a factory were developed and are issued directly from meat factories. Over time, farm level reports, reports for veterinary practitioners, and regional reports will also be developed and made available through the ICBF website.

Results: The Beef HealthCheck programme has been rolled out in meat plants across Ireland. Seven large meat processors are involved in the programme and when complete the Beef HealthCheck programme will be receiving information on approximately 80% of the cattle slaughtered in Ireland. Farmers are receiving Beef HealthCheck standardised batch

level reports on the liver and lung lesions found in their cattle at slaughter. Data is accumulating in the ICBF database where it will be used to provide further reports to farmers and their veterinary practitioners and in the further development, by ICBF, of economic breeding indices. The information captured will also allow the effects of liver fluke and pneumonia on a range of production parameters to be measured and economic impact determined.

Conclusions: Liver and lung lesions can negatively influence the carcass weight of cattle at slaughter, the time it takes cattle to reach slaughter weights, milk production and fertility. Beef HealthCheck represents a functional system for capture of information from abattoirs in a standardized way and its presentation to farmers and their veterinary practitioners. This allows them to monitor the health of cattle on farms and to implement control strategies to manage liver fluke, liver abscesses and pneumonia. In addition, it provides the basis for developing herd-level reports and monitoring and forecasting of regional and national trends.

P04-004-051

Systematic framework for control and eradication of endemic infectious diseases in cattle

Liza Rosenbaum Nielsen ¹; Søren S. Nielsen ¹; Hans Houe ¹

¹Large Animal Sciences, University of Copenhagen, Frederiksberg, Denmark

Objectives: Successful control and eradication of multiple endemic cattle diseases have been achieved in some countries, whereas elsewhere programmes have not been established, despite the required biological knowledge being in place. The objectives are: 1) to describe the individual elements of a systematic control and eradication framework, and 2) to discuss how the individual elements can be compiled for deciding, planning and carrying out effective control or eradication of endemic diseases in cattle, and 3) to illustrate the effect on three infectious diseases in the Danish cattle population.

Materials and Methods: Overall the evidence was established by integration of scientific results with the practical experiences obtained for three diseases over a two-decade period. Thus, published and unpublished data and methods used in the Danish control and eradication programmes for the diseases caused by bovine virus diarrhoea virus (BVDV), Salmonella Dublin (S. Dublin) and Mycobacterium avium subsp. paratuberculosis (MAP) were compiled and grouped into elements evaluated to be needed in an effective control or eradication programme, and the consequential change in prevalence over time was illustrated.

We address the questions: Why is it important or relevant to control or eradicate a specific infection? What should be done to control and eradicate it? Which knowledge gaps exist? Who should be involved and informed, and how should the programme be organised? Where should the programme be carried out in different phases of the programme? Which measures should be used to monitor progress? And when is control and eradication deemed to be achieved?

The basic idea is to enable "disease profiling", which is partially governed by the infectious agent characteristics and its interaction with the host and environment, partially by the impact on, and interaction with, society. It is acknowledged that the necessary information for a sufficient profile often evolve over many years. The profile makes it transparent on which ground the decision is made and how the disease can be addressed.

Results: The key elements include socioeconomic aspects such as establishment of needs and characterisation of motivation for carrying out the programme, animal and veterinary science including assessment of biosecurity and purpose specific test-strategies, organisational issues such as preliminary assessment of programme elements in pilot projects, considerations on resource allocation, administrative and logistic matters, along with aspects such as training, education and communication in general.

All programmes started out with a voluntary control phase supported by surveillance for herd classification and animal testing for management of the infection within herd. For BVDV and S. Dublin extensive surveillance, multiple legislative orders defining control measures and regionalisation, and several pilot projects and communication campaigns were essential parts of the eradication efforts.

The BVDV-programme was initiated in 1994, where the dairy herd level prevalence was 39%. Eradication was achieved in 2006, and all cattle herds are under continuous surveillance for BVDV. The S. Dublin programme was initiated in 2002 at a dairy herd level prevalence of 26%, which today is reduced to 7% and strict legislation applies to prevent spread between herds. The voluntary paratuberculosis control programme began in 2006 when an estimated 85% dairy herds were infected. The main goal of the programme was to reduce the within-herd prevalence, and hence the consequences of the infection. The median within-herd test prevalence in enrolled herds has decreased from approximately 10 to 3%.

Conclusions: We have compiled critical information of generic relevance for effective control and eradication of loss-provoking endemic infectious diseases in cattle into a framework that allows for a systematic, resource-effective approach to combatting endemic infectious diseases. We anticipate the systematic framework approach to be of great interest to an audience interested in National Animal Health Programmes in the cattle sectors.

Livestock Disease Surveillance in Rural Southwestern US, Ten Years of ALIRT

S Peder Cuneo ^{1,*}

¹School of Animal and Comparative Biomedical Sciences, University of Arizona, Tucson, United States

Objectives: To develop properly trained and equipped first responders, to provide diagnostic support and educational outreach to livestock owners. To develop a systematic approach for sample collection in livestock disease outbreaks and to fully utilize all biological disciplines within a land grant university.

Materials and Methods: The underlying events and reasons for the development of the ALIRT program will be presented. Materials used in training and equipping ALIRT First Responders, ALIRT response protocols and training materials for livestock owners will be presented. A typical ALIRT response will be presented. The ALIRT program has sponsored three national and international meetings regarding livestock disease response and investigation, highlights of these meetings will be presented as well as future plans involving veterinary medical education

Results: The ALIRT program has a ten year history of innovative development of training and response in dealing with livestock losses in the southwestern United States. The ALIRT program can provide a

template for training veterinary students, extension agents, and livestock owners on how to develop a response plan for investigation, diagnosis and response to livestock losses. The ALIRT field investigation protocol provides a template for field veterinarians and extension agents in dealing with livestock losses. The ALIRT field protocol can be used to veterinary students in livestock disease outbreak investigation

Conclusions: The ALIRT program can provide a template for training veterinary students, extension agents, and livestock owners on how to develop a response plan for investigation, diagnosis and response to livestock losses.

Effects of lactobacillus inoculants on fermentation characteristics of wilted Alfalfa with orange pulp silage

Mojtaba Karimi ¹, maghsoud Besharati ¹, rashid safari ¹, akbar Taghizadeh ¹

¹university of Tabriz, Tabriz, Iran, Islamic Republic Of

Objectives: This study was conducted to document the effects of Lactobacillus buchneri 40788 inoculants (LAB, LALSIL[®]) on the dry matter content (DM), pH, aerobic stability and microbial population in wilted and chopped (2cm) alfalfa (35% DM) with orange pulp (25% DM) silage.

Materials and Methods: Experimental treatments were wilted alfalfa with no additive (control), wilted Alfalfa and orange pulp (1750 g wilted Alfalfa mixed with 750 g fresh orange pulp) treated with LAB for final application rates of 0, 2.5, 5 and 7.5 g LAB inoculant/ton of wilted alfalfa and orange pulp (LAB0, LAB1, LAB2, LAB3 respectively). Experimental treatments were ensiled in triplicate laboratory mini silos for 90d at room temperature. For isolation and enumeration of microorganisms, 11 g of fresh forage or silage was added to 99 ml of sterile 70mM potassium phosphate buffer (pH 7) and agitated for 60 s on the highest setting in a laboratory blender. Three consecutive dilutions were plated in triplicate onto a semi-selective lactobacilli Medium (MRS) for the isolation of LAB, onto nutrient agar (NA) for the isolation of total bacteria, and onto Sabouraud's dextrose agar (SDA) for the isolation of yeasts and molds.

Results: DM was not affected by treatments at the end of the experimental period. The pH of all silages was less than 4.55, but pH was significantly higher for control compared with silages containing orange pulp (p<0.05). Yeasts and molds count on sabouraud dextrose agar for LAB2, LAB3 treatments were lower than other treatments (p<0.05). Inoculation of LAB caused a significant increase in lactobacillus population on MRS agar for LAB1, LAB2, LAB3 treatments (6.0×10⁷, 7.5×10⁷ and 1.0×10⁸ cfu/gr respectively). Total culturable bacteria in nutrient agar showed significant increase in treatments treated with LAB compare to control (p<0.05). Treating alfalfa silage with orange pulp and LAB improved aerobic stabilities of experimental treatments in comparison to LAB0, significantly (144, 192, 200 vs. 56 and 72 h in, LAB1, LAB2, LAB3 compare to LAB0 and control, respectively).

Conclusions: These findings show that LAB can improve the aerobic stability and quality of silage in laboratory silos and that might orange pulp and LAB improve silage quality and cause better management of silage in the farm.

SURVEILLANCE OF BOVINE ENCEPHALITIS: PAPILOMAVIRUS AS CASUAL AGENT (PRELIMINARY RESULTS)

Jessica F. Costa ¹, Talita P. S. Moura ¹, Waleska V. B. Loiacono ¹, Luana C. Oliveira ¹, Enio Mori ², Maria do Carmo C. S. H. Lara ¹, Liria H. Okuda ¹, Edviges M. Pituco ¹, Claudia Del Fava ¹

¹Centro de Pesquisa e Desenvolvimento de Sanidade Animal, Instituto Biológico, São Paulo, Brazil, ²Instituto Pasteur, São Paulo, Brazil

Objectives: Bovine encephalitis are generally fatal diseases, with impact in food safety. The Biological Institute of São Paulo State collaborates with the Brazilian national program for surveillance of bovine neurological syndrome, performing the differential diagnosis. The Bovine Papillomavirus (BPV) causes papilloma in skin, and tumors in the digestive and genital systems, but experimental inoculation of BPV into calves' meninges caused papillomatosis in brain. This research aimed to study the frequency of cattle with neurological syndrome, who presented histopathological lesions and BPV DNA in central nervous system (CNS).

Materials and Methods: This research was approved by the Bioethics Committee in Animal Research of the Biological Institute (CETEA-IB), registry number 134/14. A total of 300 CNS samples from several Brazilian regions, in the period from January 2012 to September 2015, were submitted to differential diagnosis of neurological syndrome. There were selected negative samples to rabies (direct immunofluorescence), Neospora caninum, BVDV, BoHV-5, and catarrhal malignant fever (PCR). CNS tissues were fixed in buffered formalin 10%, and submitted to histological analysis using hematoxylin-eosin staining in paraffin embedded tissue. For BPV analysis, DNA was extracted from refrigerated samples by Guanidinium thiocyanate-phenol-chloroform method. The amplification of the DNA fragment was performed by generic primers, with nucleotide sequence of the gene that codifies the L1 protein of the BPV capsid: FAP59 (5'-TAA CWG TIG GIC AYC CWT ATT-3'), and FAP64 (5'-CCW ATA TCW VHC ATI TCI CCA TC-3'). The negative BPV PCR control was ultra-pure water, and the positive BPV PCR control was a BPV-6 DNA from a skin papilloma diluted 1:10). The mix used in the PCR was: 12.5 µL Master Mix Promega[®], 3.75 µL Nuclease Free Water, 1.875 µL each primer diluted 10 pmol, and 5 µL of DNA sample. The program of amplification consisted in initial denaturation 94°C/5 minutes, 45 cycles of amplification (94°C/1 minute; 49.3°C/1 minute; 72°C/1 minute) and final extension 72°C for 5 minutes. The samples were considered positive when they presented a band corresponding 478 bp with equal or stronger similarity to the positive control.

Results: It was found 4.3% (13/300) CNS samples positive to BPV PCR. In 11 of these 13 positive samples (84.6%), there was no histopathological alterations in CNS, and 2 (15.4%) had typical lesions of non-purulent meningoencephalitis. Considering the gender, 69.2% of the positive samples were female, and 30.8% male. The animals were aged from 5 to 168 months old, with a higher frequency of positivity from 24 to 36 (30.8%). In the positive cases, 38.6% were dairy cattle, 30.7% crossbreed, and 23% beef cattle. The low number of positive BPV samples didn't allowed the statistical analysis among PCR positivity, histopathological lesions, gender, and breed. The positive BPV DNA samples had no papilloma, but presented unspecific inflammatory non purulent lesions.

Conclusions: These preliminary results suggest low occurrence of BPV in natural infection in CNS of cattle with neurological syndrome. The next step of this study will be the genome sequencing of the positive samples, in order to conclude the frequency of BPV, and to know what genotype of BPV is being found in the CNS. The viral phylogenetic tree will be

constructed for understanding the molecular epidemiology of BPV in the Brazilian bovine population.

Financial support: FAPESP grant number 2014/04322-5; Fapesp Scholarship TT-3 number 2015/14443-7; PIBIC CNPq Scholarship 167846/2013-2 and 155066/2014-5.

P04-004-056

Animal Health Ireland Parasite Control Technical Working Group leaflets on Coccidiosis and Cryptosporidiosis as a method of knowledge transfer.

Rebecca Carroll¹, A. Forbes², J. O'Flaherty¹, D.A. Graham¹

¹Animal Health Ireland, Carrick-on-Shannon, Co. Leitrim, Ireland,

²School of Veterinary Medicine, Glasgow University, Glasgow, United Kingdom

Objectives: Animal Health Ireland (AHI) is a not for profit organisation tasked with pursuing control strategies for economically important diseases of cattle which are not subject to international regulation. AHI's Parasite Control Technical Working Group (TWG) aims to produce objective and practical guidelines for farmers, on the control of parasites affecting cattle on Irish farms.

Materials and Methods: The parasite control TWG has produced two new information leaflets: "Bovine coccidiosis – the facts" and "Cryptosporidiosis in neonatal calves", aimed at farmers and their veterinary practitioners. The leaflets have been produced following a thorough review of the literature and discussion among the Parasite Control TWG experts in the fields of parasitology and veterinary medicine. The advice is aimed specifically at Irish farmers and acknowledges the practices and conditions on Irish beef and dairy farms. The leaflets are complementary to other material produced by AHI's Calcare and Biosecurity TWGs. The leaflets contain information on the lifecycles, transmission, clinical signs, diagnosis, treatment and control of these parasites. The leaflets are available through the Animal Health Ireland website.

Results: The leaflets are a vehicle for the transfer of objective, science based knowledge to farmers. Farmers can access the information through the AHI website and the material from the leaflets is also used as the basis for articles that appear in AHI newsletters and the farming press. The leaflets are regularly referenced in material produced by AHI stakeholder organisations and in academic and media articles on parasites. Annually, AHI undertakes a series of information events on Calf health and in the spring of 2016, a section of these events focused on coccidiosis and cryptosporidiosis.

Conclusions: AHI is a trusted and reputable source of factual, up to date and independent information for the agricultural community in Ireland. The leaflets build awareness of coccidiosis and cryptosporidiosis on Irish farms and methods to control and prevent the diseases caused by these parasites.

Laboratories, Celbridge, Co. Kildare, ⁴Irish Cattle Breeding Federation,

Highfield House, Shinagh, Bandon, Co. Cork, ⁵School of Veterinary

Medicine, University College Dublin, Belfield, Dublin 4, ⁶Animal &

Biosciences, Teagasc, Moorepark, Fermoy, Co. Cork, Ireland

Objectives: Several diagnostic strategies may be used to establish the BVD status of a herd including virus testing of all animals, bulk milk antibody testing and young-stock check tests (YSCT). YSCT involves serological testing of a limited number of home-born, unvaccinated juveniles, greater than 9 months of age. Detection of BVD virus antibodies in young-stock is likely due to exposure to one or more persistently infected (PI) calves. Our objective was to evaluate the performance of a YSCT in dairy herds during the current phase of the national BVD eradication programme in Ireland.

Materials and Methods: Samples were collected in 137 dairy herds in the south west of Ireland from September to December 2014 as part of a targeted surveillance programme. Samples from qualifying juveniles stock were tested using a BVD virus total antibody ELISA (IDEXX, USA) having a positive cut-off of ≥ 0.3 S/P (99.5% specificity (Sp) and 96.3% sensitivity (Se)). The Irish Cattle Breeding Federation provided relevant details of all PIs born in 2014 and 2015 (data available from the Irish national BVD eradication programme). The programme records a calf as PI if it has at least one BVD virus positive test without a negative confirmatory test.

Descriptive data were coded and analysed in Excel (MS Office 2010). Statistical analyses were completed using Stata version 12 (StataCorp, US). Non-parametric receiver operating characteristics (ROC) analysis without covariates was applied to serological YSCT (classification variable) and BVD PI data (reference variable) to examine the usefulness of a 2014 YSCT in identifying herds in which a PI calf was born in either 2014 and/or 2015. Two datasets were constructed; herds recording at least one seropositive juvenile were deemed YSCT positive (YSCT1), and herds recording at least two seropositive juveniles deemed YSCT positive (YSCT2).

Results:

Dataset 1

Of the 27 herds in which at least one PI was born in 2014, 20 herds recorded a positive YSCT. Of herds with a PI born in 2015 (n=12), seven were YSCT positive. ROC area under the curve (AUC) values for 2014 and 2015 PI births were 0.78 and 0.66, respectively. Classifying herds on the basis of at least one serologically positive juvenile (YSCT1) yielded a Se and Sp of 74.1% and 80.9% respectively in relation to herds with a PI birth in 2014. In terms of using YSCT to identify herds which may produce a PI in the following calving season, Se and Sp were 58.3% and 72.8% respectively.

Dataset 2

If herds were classified as young-stock positive if two or more juveniles were positive (YSCT2), ROC AUC values dropped to 0.71 for 2014 born PIs and 0.56 for 2015 born PIs. Use of this YSCT2 herd classification, although improving Sp (93.6% for 2014, 86.4% for 2015) over dataset 1, caused a considerable drop in Se (48.2% for 2014, 25% for 2015).

Conclusions: Even though positive herd YSCT Se was low, YSCT1 was still found to be superior to YSCT2 in terms of Se and AUC. The Se of both YSCT1 and 2 in predicting the birth of PIs in 2015 was low. Currently, use of YSCT (particularly YSCT1) has a low Sp, resulting in “false positive” results in 2014 for 24% of herds in which no PIs were born. Future Sp of YSCT is expected to improve as national herd BVD immunity (and therefore the presence of maternally derived antibodies) reduces. Se is also expected to improve, in future, in herds that are no longer routinely tissue tag testing calves at birth.

National Animal Health Programmes

P04-004-058

Correlation between BVD blood and milk serology in first lactation dairy cows.

Michael Sexton¹ David A. Graham² Ronan O’Neill³ Pdraig O’ Sullivan⁴ Michael Doherty⁵ Luke O’Grady⁵ Riona Sayers⁶

¹Riverview Veterinary Group, Bandon, Co., Cork, ²Animal Health Ireland, 4–5 The Archways, Carrick-on-Shannon, Co. Leitrim, ³Department of Agriculture Food and the Marine, Backweston DAFM Laboratories, Celbridge, Co. Kildare, ⁴Irish Cattle Breeding Federation, Highfield House, Shinagh, Bandon, Co. Cork, ⁵School of Veterinary Medicine, University College Dublin, Belfield, Dublin 4, ⁶Animal & Biosciences, Teagasc, Moorepark, Fermoy, Co. Cork, Ireland

Objectives: Serological investigation of individual cows on dairy farms can be used as a surveillance tool to identify circulation of BVD virus. Blood or milk can be used for the purposes of serological testing. Milk may be a preferred sampling option as it is non-invasive and less expensive. The objective of this study was to investigate the correlation between blood and milk samples in first lactation dairy cows to determine if milk samples provide a viable alternative to BVD blood serological testing for herd surveillance.

Materials and Methods: Blood and milk samples were collected between September and December 2014 from five first lactation cows in 102 dairy herds in the south western region of Ireland. Both blood and milk samples were tested using the BVD virus total antibody ELISA (IDEXX, USA). A positive cut-off of ≥ 0.3 S/P was applied and samples yielding S/P ratios of ≥ 0.2 and < 0.3 were classified as inconclusive as per kit manufacturer’s instructions. Results were analysed as both continuous (ELISA readings) and categorical (positive, inconclusive, negative) data. Two herd-level categorical datasets were also constructed. Herds were categorised as positive on the basis of having at least one (herd dataset 1), or at least two (herd dataset 2) positive individuals. Negative status was assigned if either no individuals recorded positive results (herd dataset 1) or only recorded a single positive (herd dataset 2). For statistical analysis, data were sorted and coded in Excel (MS Office 2010) and imported to Stata Version 12 (StataCorp, USA). Paired t-test and Pearson (continuous data) and chi-squared and Spearman (categorical) correlation analyses were completed.

Results: Of the 102 herds studied, approximately 80% were spring-calving. A total of 47 herds vaccinated for BVD. The average lactating herd size was 69 cows (range 20-220) which is reflective of the national average. Blood and milk results were available for a total of 510 cows. Spearman and Pearson correlation analyses of individual cows yielded rho values of 0.74 and 0.87 indicating good agreement between both sample matrices. The mean S/P ratios were 0.32 and 0.52 for milk and blood respectively and significantly different ($P < 0.001$). Pearson chi-squared also highlighted a significant difference ($P < 0.001$) between

milk and blood categorical data. A total of 39 blood seropositives were classified as negative using milk samples, and 16 milk seropositives were classified as negative on blood. At a herd level, Spearman correlation rho values for herd datasets 1 and 2 were 0.71 and 0.78, respectively. Herd dataset 1 yielded seven herds that were milk positive but blood negative, and six herds that were blood positive and milk negative. Using herd dataset 2, 10 herds were blood positive and milk negative with two herds milk positive and blood negative. Chi-squared analysis of milk versus blood herd categorisation yielded P values of < 0.001 .

Conclusions: Although a strong correlation was identified between milk and blood samples analysed as both continuous and categorical data, the discrepancies between blood and milk categories at both individual animal and herd level may indicate either sensitivity or specificity issues with these sample types. Further investigation is required to elucidate whether blood analysis is less-specific than milk or milk analysis is less sensitive than blood. Data are available on the BVD viral status of each herd and further investigations are underway which should allow determination of the most appropriate surveillance sample on Irish dairy farms

Neosporosis

P04-004-167

The Importance of Fetal Pathology for Neosporosis Diagnosis and Control

Karin Orsel¹, Josh Waddington², Devon Wilson³, Malavika Rajeev⁴, Amy Sweeny⁴, Tomy Joseph⁵, Mike Grigg⁴, Stephen Raverty⁵

¹Production Animal Health, University of Calgary/Veterinary medicine, Calgary, ²Greenbelt Vet Services, Chilliwack, ³Alberta Beef Health Solutions, Picture Butte, Canada, ⁴NIH, Bethesda, United States, ⁵AHC, Abbotsford, Canada

Objectives: *Neospora caninum* has been recognized as a significant cause of bovine abortions worldwide, although a definitive diagnosis of *N. caninum* is a major challenge. Furthermore, epidemiologic findings are non-specific, as abortions can occur anytime in gestation and can be observed in an epidemic or endemic pattern. Therefore, the objectives of this study were to determine causative agents of bovine abortions and describe the prevalence and risk factors associated with *N. caninum* abortions in BC Animal Health Center (AHC) submissions retrospectively. Additionally we identify risk factors associated with fetal abortions.

Materials and Methods: Between January 2007 and July 2013, there were 182 bovine fetal submissions and from July 2013 to May 2014 active case recruitment was initiated from producers through the local veterinary clinic, resulting in another 54 abortion submissions.

Fetuses presented for necropsy underwent a standardized post mortem examination and cases were confirmed by histopathology after initial positive test results in either immunohistochemistry, serology (cELISA, Pullman, WA), or polymerase chain reaction for Apicomplexa (Np21/Np6 and ApilTS1 primers). We set a case definition for *Neospora* and performed a logistic regression finding associations between fetal Neosporosis and risk factors like breed, age, parity, season, gestation length and location.

Results: A diagnosis could be made in 64.8% of all submissions, with a confirmed etiology identified in 41.1% of submissions; 15.3% bacterial, 15.3% protozoal, 4.2% viral, 1.7% developmental, 0.8% fungal, and 3.8% mixed infections. Neosporosis was confirmed in 19.1% of all submitted fetuses from 2007-2014 and myocarditis, myositis and encephalitis were the most common microscopic findings. Between January 2007 and July 2013, 14.4% of the abortions were diagnosed as neosporosis. In contrast, with active case recruitment of fetal abortions between July 2013 and May 2014, the incidence of neosporosis increased to 40.9% of the submissions. Neosporosis was most commonly identified in fetuses between 3 to 6 months gestation and there was no significant association with dam parity. Some differences in diagnoses may be attributed to test sensitivity and specificity. Active surveillance established that immediate submission of bovine abortion samples dramatically improved diagnosis and detection of *Neospora caninum* as a significant causal agent of bovine abortion and production losses in the upper Fraser Valley (BC), a region where neosporosis is highly prevalent.

Conclusions: *N. caninum* is the most commonly diagnosed infectious etiology associated with bovine abortions. While definitive diagnoses of *N. caninum* remains challenging, use of multiple diagnostic tools including fetal pathologic examination, pathogen identification by PCR, IHC and serology, combined with epidemiological data, can provide valuable information for pathologists, veterinarians and producers. Active surveillance could also increase understanding of *N. caninum* epidemiology. With known causes of bovine fetal losses and abortions, better focused strategies to mitigate the economic impact of fetal losses can be developed.

Neosporosis

P04-004-168

Seroprevalence of *Neospora caninum* infection in dairy cattle in central and northeastern Poland

Corinna N. Weber¹, Sławomir J. Kowalczyk², Michał Czopowicz², Lucjan Witkowski², Elisabeth Müller¹, Jaroslav Kaba²

¹Laboklin GmbH & Co. KG, Bad Kissingen, Germany, ²Laboratory of Veterinary Epidemiology and Economics, Faculty of Veterinary Medicine, Warsaw University of Life Sciences, Warsaw, Poland

Objectives: A cross-sectional study was carried out to characterize the seroprevalence of *Neospora caninum* infection in cattle in central and northeastern Poland and investigate the relationship between grazing policy and *N. caninum* infection.

Materials and Methods: Ninety seven dairy cattle herds from 2 provinces of Poland (Podlaskie and Łódzkie) were randomly enrolled in the study. Sample size from each herd ranged from 3 to 16 dairy cows with median of 8 (interquartile range from 6 to 9) and a total number of 734 cows were enrolled. Moreover, 1 to 5 calves (<18 month-old) were randomly selected="selected" in 61 of 97 herds (175 calves in all). The animals were screened with a commercial competitive ELISA (Bio-X Diagnostics, Belgium). Then, all 909 tested animals were classified into 5 age categories: <18 months (n=175), 18-36 (n=214), 37-60 (n=285), 61-84 (n=156), >84 (n=79) and true individual-level seroprevalence was calculated for each of them. To calculate true-herd level seroprevalence the test sensitivity and specificity were adjusted from an individual- to a herd-level using FreeCalc method.

Results: The true herd-level seroprevalence of *N. caninum* infection was 56.7% (95% CI: 46.8%, 66.1%). One hundred forty three of 734 cows (19.5%) were seropositive which gave the true overall individual-level seroprevalence of 20.1% (95% CI: 17.4%, 23.2%). Percentage of seropositive cows in each herd varied from 6% to 80%. No difference between seropositive and seronegative herds was found with respect to the median herd size (21.5 vs. 21.0 dairy cows; p=0.645), grazing policy (full-day: 42.9% vs. 45.0%, half-day: 8.9% vs. 12.5%, no grazing: 48.2% vs. 42.5%, respectively; p=0.690) nor grazing season length (median of 5.0 months in both herd groups; p=0.445). Individual-level seroprevalence proved to increase along with animal age (p=0.018).

Conclusions: *Neospora caninum* is a protozoan of two-host life cycle with a domestic dog or another representative of Canidae family as a definitive host. To date, wide range of animal species susceptible to *N. caninum* has been identified, with cattle of the highest economic importance. The infection and *Neospora*-associated bovine abortion have already been reported from virtually all European countries. Herd-level seroprevalences varied from below 1% (Norway) to almost 90% (Spain). As seen in this study, *N. caninum* infection is widespread in Polish dairy cattle population and thus has to be considered as a potential cause of spontaneous abortions.

Comments: This study was financially supported by the European Union Seventh Framework Programme for the Research and Technological Development "GLOWORM" no. FP7-KBBE-2011-5 288975.

Horizontally or Vertically Infected Dairy Cattle with *Neospora caninum*: rate of transmission to offspring and serological characterization

Raphaël Guatteo¹ Emma Dupuis¹ Justine Boyer¹ Alain Joly² Christophe Chartier¹ Caroline Lantuejoul³ Grégoire Kuntz⁴

¹UMR 1300 Oniris & INRA BioEpAR, Nantes, ²GDS Bretagne, Vannes, ³FRGDS Pays de la Loire, Nantes, ⁴GDS Bretagne, Ploufragan, France

Objectives: The principal route for *Neospora caninum* infection is supposed to be transplacental (vertical), the congenitally infected cow passing the infection to multiple offspring. In case of postnatal (horizontal) infection, the dam would pass the infection to the immediate offspring (or abort) and would pass to a lower rate the infection to further offspring. But these reports are based on a small number of experimental studies. The objective was to describe the rate of transmission to the offspring depending on the supposed route of infection and to investigate the value of ELISA test (single or repeated) to discriminate the route of infection.

Materials and Methods: The determination of the rate of transmission to their offspring was calculated based on large dataset (251 548 blood ELISA tests among which 19 547 cattle with at least 2 serological results) coming from the control plans implemented in the western part of France for the last 15 years in dairy herds facing repeated abortions. A cow was supposed to be infected by horizontal route when a seroconversion occurred during the control plan. A cow was supposed to be infected by vertical route if its own dam was already seropositive before its birth and if this cow was seropositive from its first testing (occurring after 6 months of age). Then, the number of offspring detected seropositive or seronegative (after 6 months of age) was compared between two groups using chi-square test. In a second step, a longitudinal follow-up was conducted in 325 dairy cows from 20 dairy herds with repeated abortions and a within herd seroprevalence > 20% suggesting the co-existence of both transmissions routes. Kinetics of serological results over time was compared between supposed infection routes. In a last step, the putative informative value of the optical density of the first positive ELISA tests was investigated using receiver operating characteristic (ROC) method.

Results: After the selection process, only 69 and 60 cows could be considered as infected through vertical and horizontal routes respectively. This small number was related (i) to the quite systematic culling of seropositive animals due to control plans and thus did not make the follow-up of seropositive animals and their offspring easier, (ii) the fact that male calves were not tested. The rate of transmission to the offspring was found significantly different ($p=0,03$) between supposed congenitally infected dam (65%) and supposed postnatal infected ones (47%) confirming a lower transmission rate for horizontal route but to a lower extent that previously described although horizontal contamination of naïve calves after birth could not be fully excluded. Over a 12 months period, less than 8% of supposed vertically infected cows became seronegative while 35% and 44% of supposed horizontally infected ones were seronegative 6 months and 9 months respectively after the first positive result. Lastly with the serological tests used in the follow-up, the mean of S/P ratio were significantly higher for supposed vertically infected dams. The ROC curve indicated a cut-off allowing reaching specificity of 70% and sensitivity of 50% to distinguish supposed horizontally infected dams.

Conclusions: These results, based on a large dataset under field conditions, confirm difference in transmission rate to the offspring depending on the route of infection for the cow but to a lower extent of that was already reported. ELISA quantitative results or serological follow-up could be used, with prevalence and filiations data, to distinguish infection route and therefore prioritize culling.

Reduction of detrimental effect of Aflatoxin B1 on In Vitro rumen fermentation by addition of MycosorbZabihollah Nemati¹, Maghsoud Besharati¹, Mojtaba Karimi¹¹Animal Science, university of Tabriz, Tabriz, Iran, Islamic Republic Of

Objectives: The objective of the present study was to investigate the effect of different doses of Mycosorb on in vitro gas production of alfalfa hay based diet and final PH in the cultures after 120-h incubation in the present of 1µg/ml aflatoxin B1.

Materials and Methods: Ruminant liquor was collected after morning feeding from 2 cannulated sheep. Ruminant liquor was immediately filtered through four layers of cheesecloth and filtered rumen liquor was used as a source of inoculum. The resulting ruminal liquor was purged with deoxygenated CO₂ before use as the inoculum. Briefly, 300 mg of diet were weighed in to 50-ml bottles and incubated in buffered rumen fluid for 120 h and the gas production recorded at 4, 6, 8, 12, 24, 48, 72, 96 and 120 h. Experimental treatments were four dose levels of glucomannan (Mycosorb™) at 0, 0.5, 5 and 10 gr/L in the present of 1µg/ml aflatoxin B1. After 120 h incubation, bottles were opened and final pH of culture fluids was measured.

Results: The results showed that cumulative gas production at 24, 48, 72, 96 and 120h after incubation differed significantly. The lower volume of gas production was observed at the zero dose of Mycosorb in the present of aflatoxin B1. Mycosorb addition affected the rate and cumulative gas production so by increasing the level of Mycosorb from 0 to 10 gr/L, the cumulative gas production increased from 389 to 692 ml/g dry matter, respectively ($p < 0.05$). Final culture pH was significantly affected by aflatoxin B1 binder. The pH was decreased significantly due to addition of Mycosorb at the concentration of 5 or 10 gr/L ($p < 0.05$).

Conclusions: It was concluded from the present study that addition of Mycosorb improves rumen metabolism and has potential to reduce detrimental effect of Aflatoxin B1 on rumen fermentation of diet. This product can be incorporated in to animal feed to prevent disease associated to aflatoxicosis.

Impact of Virginiamycin used as Growth Promoter on the Ruminant Microbiota of Feedlot CattleBruna P. Santos¹, José A. Bessegatto¹, Lais R. Paulino¹, Julio A. Lisboa¹, Amauri A. Alfieri¹, Carlos H. Montemor¹, Scott Weese², Marcio Costa^{1,2}¹Universidade Estadual de Londrina, Brazil, Londrina, Brazil,²University of Guelph, Guelph, Canada

Objectives: The ruminal microbiota promotes digestion and production of volatile fatty acids, the main energy source for ruminants. The composition of ruminal microbiota may be related with fermentation efficiency, and can be modified by various factors. The mechanisms by which antibiotic growth promoters (AGPs) modify the ruminal microbiota to increase feed conversion rates have not been fully elucidated. The aim of this study was to compare the microbiota in the rumen of beef cattle receiving virginiamycin with a control group at the exit from a feedlot operation.

Materials and Methods: Fifty crossbred beef cattle (26 females and 24 males) housed in a feedlot operation were enrolled. Animals were divided in two groups: ATB (n=25), in which animals received virginiamycin (340mg/360Kg body weight) and CON (n=25), in which animals received the same diet, but without any AGP. Slaughter was carried with 66, 88 or 116 days of confinement, depending on their body score condition. Ruminant fluid samples were taken during slaughter directly from the medial portion of the rumen, and immediately refrigerated until frozen at -80°C. DNA extraction was performed using a commercial kit and the V4 region of the 16S rRNA gene amplified by PCR and sequenced with an Illumina MiSeq platform. The different species composing the microbiota (community membership) and the bacterial composition taking into account the evenness of each species (community structure) were addressed respectively by the Classical Jaccard and the Yue and Clayton indices. A P-test was used to compare membership and structure and a t test to compare relative abundances found within each group.

Results: Community membership and structure present in the rumen of animals treated with virginiamycin were statistically different from ones found in the control group ($P=0,001$ and $P=0,005$, respectively). However, no significant differences were observed in the relative abundance of the main phyla and genera (all $P>0.010$), suggesting that changes were likely more evident in less abundant species. More than 50% of bacteria present in the rumen of both groups were classified as Firmicutes. The second most abundant phylum was Bacteroidetes followed by Proteobacteria, Fibrobacteres, Verrucomicrobia and Spirochaetes.

Conclusions: The use of virginiamycin as AGP significantly affected membership and structure of bacterial communities present in the rumen of feedlot cattle at the time of slaughter.

An assessment of the effectiveness of a hypocalcaemia prevention protocol on Irish dairy farms during the spring of 2016Maresa Sheehan¹, Colm Brady¹, John Fagan², Seamus Fagan², Denise Murphy², William Fitzgerald¹, Joe Patton³¹Department of Agriculture, Food and the Marine, Regional Veterinary Laboratory, Hebron Road, Kilkenny, ²Department of Agriculture, Food and the Marine, Regional Veterinary Laboratory, Coosan, Athlone, Co Westmeath, ³Teagasc, Grange Research Centre, Dunsany, Co Meath, Ireland

Objectives: To advise and help to implement a protocol for the prevention and control of clinical and subclinical hypocalcaemia in twelve selected dairy herds that have a history of hypocalcaemia related problems, including milk fever, prolonged parturition, slow weak calves, retained foetal membranes and metritis. An assessment of the protocol's effectiveness will be made by measuring the number of hypocalcaemia related events that occur on the study farms and comparing them to farm records for 2015.

Materials and Methods: The study farmers completed a questionnaire detailing the number of hypocalcaemia related events (e.g. milk fever, slow calvings, weak calves, retained foetal membranes, metritis) and hypocalcaemia prophylaxis used on their farms in spring 2015. Details of body condition score (BCS), silage analysis, mineral supplementation

and any additional components of the dry cow diet were collected for each farm in November 2015. Based on this information an individual protocol document was issued to each farm with the aim of achieving the following targets; BCS of 3.25 at calving, 0.40% magnesium, 0.3% phosphorous, and a maximum of 2.0% potassium in the diet DM for late gestation dry cows. Blood samples will be collected from ten cows four weeks prior to start of calving and again when the first six cows have calved to evaluate the success of implemented measures by measuring serum metabolites including calcium and magnesium levels. Private veterinary practitioners (PVPs) have been instructed to take a blood sample from any periparturient cow (within 48 hours) that he/she attends on the study farms during spring 2016. The incidence and treatment of conditions associated with hypocalcaemia and the use of hypocalcaemia prophylactic treatment will be recorded by the farmers. All perinatal mortality on the study farms will be submitted to the local Department of Agriculture and the Marine (DAFM) laboratories for post mortem examination.

Results: The incidence of hypocalcaemia related conditions on these farms, the use of hypocalcaemia prophylactic treatment and the results of blood samples will be collated for each farm. The success of the protocol will be assessed by comparing these results to 2015 farm records. The specific measure that will be used will vary from farm to farm depending on the particular hypocalcaemia related issue the farmer experienced most in 2015. Therefore on some farms the incidence of milk fever will be used while on another the incidence of prolonged parturition will be more appropriate. Based on the study findings and the practical experience of the farmers, the protocol will be refined accordingly to be applicable for dairy farms in Ireland.

Conclusions: We aim to publish the advice as a joint DAFM Laboratories/ Teagasc protocol for use by private veterinary practitioners and Teagasc Advisers to prevent subclinical and clinical hypocalcaemia on farms. It is hoped that the results of this study may generate further areas of research and collaboration between Teagasc, DAFM laboratories and PVPs for the improvement of Irish Agriculture.

Effects of chemical treatment of barley with tannic acid or alum on blood metabolites and productive performance of lactating Holstein dairy cow

Einollah Abdi Ghezaljah^{1,*}

¹Ahar Faculty of Agriculture and Natural Resources, Tabriz, Iran, Islamic Republic Of

Objectives: Barley grain is poorly utilized by ruminants due to its rapid degradation in rumen. Barley processing is imperative to maximize its utilization by feedlot and dairy cattle. The objectives of this study were to evaluate the effects of chemical treatment of barley with tannic acid or alum on blood metabolites, dry matter digestibility and productive performance of lactating Holstein dairy cow.

Materials and Methods: An experiment was conducted to evaluate the effects of chemical treatment of barley grain with tannic acid and alum (KAl(SO₄)₂) on blood metabolites and productive performance of lactating Holstein dairy cow. In this experiment a completely randomized design with 18 cows (average milk production, 34.7 kg/d), three treatments and 6 cows per each treatment were employed. The experimental diets 1 through 3 contained untreated barley, barley treated with tannic acid (5% weight), and Alum (5% weight) respectively. The cows were fed

individually ad libitum three per day. Daily milk yield was recorded and samples of the milk were taken three times per week, also samples of rumen liquors, urea and blood were taken in end of period.

Results: There were significant differences (P<0.05) between treatments in dry matter intake. Diets containing barley treated with tannic acid had the highest dry matter intake and difference were significant (P<0.05) between treatments. In this experiment body weight change and fat corrected milk of cows were not affected by experimental diets. Fat percent of milk were increased by feeding ration containing barley treated with tannic acid (p<0.05). The concentration of lactose, protein and solid non fat in milk were not affected by rations. The pH of cow's rumen liquor and urea were significantly different between rations. Also concentration of glucose, calcium, phosphorus, sodium, cholesterol, triglycerides, magnesium, potassium and total protein in blood plasma of cows received different diets were not different (p>0.05) but blood urea nitrogen and glucose concentrations of cows received diet containing barley treated with tannic acid were higher than other treatments.

Conclusions: On the basis of these data, we can conclude that feeding barley treated by tannic acid or Alum increase dry matter intake and milk yield.

Red Blood Cell Profile And Oxidative Stress In Cattle Feedlot Fed With Brachiaria Sp Hay And Supplemented With Antioxidants

Roberta Silva^{1,*}Gustavo L. Costa²Paulo Henrique J. Cunha²Maria Clorinda S. Fioravanti²

¹Veterinary Medicine, Faculdades Objetivo, ²Veterinary School, Federal University of Goiás, Goiânia, Brazil

Objectives: Brachiaria sp species contain sporidesmins, which lead to lipid peroxidation and oxidative stress due oxidation. The aim of the present study was to evaluate the effects of different antioxidants in Nelore cattle fed with Brachiaria sp in the prevention of lipid peroxidation in cell membranes.

Materials and Methods: The study was conducted at the Veterinary School's farm named Tomé Pinto of the Federal University of Goiás, in São Francisco de Goiás, GO. A total number of 40 animals were divided into five groups being confined for 105 days. The experimental design was completely randomized with five treatments: Group 1: non supplementation – control; Group 2: supplementation of selenium and vitamin E (10 mg of selenium and 1000 IU of vitamin E / animal / day); Group 3: zinc supplementation (600 mg zinc / animal / day); Group 4: selenium supplementation (10 mg selenium / animal / day) and Group 5: vitamin E supplementation (1000 IU vitamin E / animal / day). Animals were fed twice a day and had access to water ad libitum. The diet followed the proportion of 70:30 for forage and concentrate, respectively. Blood samples were harvested by venous puncture. The samples were stored in heparinized tubes and then analyzed. To evaluate oxidative stress, erythrocyte membrane characterization (red blood cells, hemoglobin and packed cell volume), TBARS, GSH-T, GSH-Px, SOD and CAT were performed.

Results: The parameters analyzed in erythrogram not influenced by the different supplementation regimens adopted throughout the experiment (p>0.05). Among the lipid peroxidation markers, there was statistical difference between the treatments proposed for the measurement

of TBARS ($p < 0.05$) in the animals who received supplementation of selenium and vitamin E showed greater lipid stability. The other oxidative stress markers present numerical variations between the standard treatment, but this variation did not provide biological changes in animals.

Conclusions: No oxidative stress was detected during the experimental period when animals were confined even when using antioxidants. Additionally, selenium and vitamin E combined in same diet seemed to cause less deleterious alterations on the erythrocyte.

Nutrition & Metabolic Diseases

Can a natural growth promoter improve the health of dairy calves?

Sabine Pruckner¹Theodora Höger²; Barbara Doupovec²Attila Kovács¹Gerd Schatzmayr²

¹Biomin Holding GmbH, 3131 Getzersdorf, ²Biomin Holding GmbH, 3430 Tulln, Austria

Objectives: An increasing number of antibiotic-resistant pathogens is currently being discovered in conventional dairy production. Practices such as applying antibiotics for prophylactic health benefits allow pathogens to build up resistances (Call et al., 2008). A broad range of alternative substances, such as phytogenics, organic acids and salts thereof, can, however, also inhibit pathogenic bacteria. The aim of this feeding trial is to test the dosage-dependent effects of a product consisting of salts of organic acids, a phytochemical, and a permeabilising substance (Biotronic® PX Top3) on the health and performance of Holstein calves.

Materials and Methods: All animals were allocated to four groups, one control with standard diet only and three groups treated with the product Biotronic® PX Top3: Standard diet + 3.0 g product per calf per day in milk for ten weeks, standard diet + 3.0 g product per calf per day in milk during weeks one to four and 1.5 g product per calf per day in milk during weeks five to ten, or standard diet + 6.0 g product per calf per day in milk for ten weeks.

The following parameters were assessed weekly: Body weight, faeces consistency; nasal and ocular discharge scores, and coughing scores. Independent samples Kruskal-Wallis-tests were carried out using SPSS 19.

Results: Lower scores, indicating improved health, as well as increased average daily weight gains were recorded in all treated groups: Total average nasal and ocular discharge, coughing, and faeces consistency scores in the control group (nose 0.72, eyes 0.63, coughing 0.60, and faeces 0.90) were significantly higher than those in the treated groups (nose 0.30-0.32, eyes 0.22-0.26, coughing 0.12-0.23, and faeces 0.32-0.40 respectively), with $p < 0.05$.

The average daily weight gain was also significantly ($p < 0.05$) improved by the product: The untreated group showed an average daily weight gain of $701 \text{ g} \cdot \text{d}^{-1}$, whereas the calves treated with 6.0 g of the product per day gained $838 \text{ g} \cdot \text{d}^{-1}$.

Conclusions: The product (Biotronic® PX Top3) shows beneficial effects on the health of calves in all three concentrations: It significantly reduced nasal and ocular discharge as well as coughing ($p < 0.05$). Furthermore, it improved the consistency of faeces significantly ($p < 0.05$) and the average daily weight gain could be increased significantly ($p < 0.05$) in the group treated with 6.0 g of product per day and calf.

Effects of prolonged consumption of water with elevated nitrate levels on certain biochemical parameters of dairy cattle and use of clinoptilolite

P.D. Katsoulou¹M.A. Karatzia¹Z. Polizopoulou²P. Florou-Paneri³H. Karatzias¹

¹Clinic of Farm Animals, School of Veterinary Sciences, ²Diagnostic Laboratory, School of Veterinary Sciences, ³Laboratory of Animal Nutrition, School of Veterinary Sciences, Aristotle University of Thessaloniki, Greece, Thessaloniki, Greece

Objectives: Elevated levels of nitrates in feed and water can pose a significant health risk for dairy cattle. The objective of the present study was to investigate the effect of prolonged consumption of water naturally contaminated with nitrates on certain biochemical parameters in dairy cows. Concurrently, it was further examined whether the in-feed inclusion of clinoptilolite, a natural zeolite with high selectivity for ammonia cations, could ameliorate nitrate consumption consequences.

Materials and Methods: Two experiments were run simultaneously for the purpose of the study. In the first experiment (Exp.1) farms 1 and 2 were assigned into two groups according to the nitrate levels in the borehole water of the previous year. The first group (NG) consisted of the farm 1 (milk yield; MY 35 kg/cow/day) that had nitrate levels > 40 ppm and the second one (CG) of the farm 2 (MY 36 kg/cow/day) that had water nitrate levels < 40 ppm. In the second experiment (Exp.2) farms 3 and 4 were assigned into two groups according to the nitrate levels in the borehole water and the use of clinoptilolite as follows: the first group (NC) consisted of the farm 3 (MY 31 kg/cow/day) that had nitrate levels > 40 ppm and used clinoptilolite as feed additive at the rate of 2.5% of concentrates. The second one (CG) consisted of the farm 4 (MY 29 kg/cow/day) that had water nitrate levels < 40 ppm without adding clinoptilolite in the ration. Both experiments lasted 6 months. Each farm was visited 3 times, at the onset of the experiment and then at 3-month intervals. At each visit, 15 clinically healthy dairy cows, 5 early lactation cows (< 150 days in milk; DIM), 5 late lactation cows (≥ 150 DIM) and 5 dry cows were selected randomly for blood sampling. Blood glucose and beta-hydroxybutyrate (BHBA) levels were determined on farm with a portable device. In serum, the concentrations of BUN, albumins, Ca, P, K, Na, Mg, Fe, Cu and Zn and the activities of AST and γ -GT were determined using an automatic biochemistry analyzer and flame atomic absorption spectrophotometry. The data was analyzed with SPSS® 21.

Results: The average water nitrate levels during the experimental period were 87 ± 12.5 ppm for farm 1, 4 ± 1.5 ppm for farm 2, 13 ± 2.4 ppm for farm 3 and 76 ± 14.2 ppm for farm 4. Blood BHBA concentration was significantly higher in the late lactation cows of the farms with high nitrate levels compared to those with low nitrates in both experiments (Exp.1: 0.78 ± 0.08 and 0.42 ± 0.03 mmol/l for groups NG and CG, respectively, $P < 0.05$; Exp. 2: 0.85 ± 0.06 and 0.65 ± 0.03 mmol/l for groups NC and CG, respectively, $P < 0.05$). Blood glucose concentration was also significantly higher in NG than the controls in the early lactation cows in Exp. 1 (3.13 ± 0.10 and 2.82 ± 0.12 mmol/l for groups NG and CG, $P < 0.05$). Average BUN values in the same experiment were significantly higher in NG compared to CG in all three categories of cows (early lactation: 7.14 ± 0.20 and 5.45 ± 0.41 mmol/l, for groups NG and CG, $P < 0.05$; late lactation: 6.43 ± 0.25 and 5.42 ± 0.26 mmol/l for groups NG and CG,

P<0.05; dry cows: 6.64±0.42 and 3.64±0.16 mmol/l for groups NG and CG, P<0.05). In Exp. 2, BUN concentration was significantly lower in NC group compared to the controls in early (3.45±0.24 and 5.39±0.46 mmol/l for groups NC and CG, P<0.05) and late lactation cows (3.50±0.18 and 4.68±0.38 mmol/l for groups NC and CG, P<0.05) whereas, it was unaffected in dry cows (3.48±0.40 and 3.82±0.39 for groups NC and CG, P>0.05). The other biochemical parameters evaluated were not significantly affected by nitrates' consumption (P>0.05) in either experiment.

Conclusions: The prolonged consumption of water with increased nitrate levels increase BUN and BHBA concentrations and, to some degree, impairs protein metabolism and glucose utilization. The dietary administration of clinoptilolite can ameliorate nitrates' effects on BUN, protein metabolism and glucose utilization, but not on BHBA concentration.

Nutrition & Metabolic Diseases

P01-001-033

Prevalence of subclinical hypocalcemia in German dairy herds

Peter L. Venjakob¹ Stefan Borchardt¹ Wolfgang Heuwieser¹

¹Clinic for Animal Reproduction, Faculty of Veterinary Medicine, Freie Universität Berlin, Berlin, Germany

Objectives: Cows with subclinical hypocalcemia have no clinical signs of hypocalcemia but are more susceptible to other diseases. The objective of this study was to determine the prevalence of subclinical hypocalcemia in German dairy herds.

Materials and Methods: A multi-center study was performed involving 108 dairy herds and 26 different veterinary practitioners to determine the prevalence of subclinical hypocalcemia on German dairy farms. A sample size of about 1,300 animals with 12 animals per herd was required to estimate the true prevalence of subclinical hypocalcemia with 95 % confidence and 5 % precision. At least 12 serum blood samples were drawn on each farm from animals 0 to 48 hours after parturition. Calcium, magnesium and phosphorous was analyzed in a commercial laboratory. Subclinical hypocalcemia was defined as blood calcium below 2.0 mmol/l. Herds were classified into negative (0 to 2/ 12), borderline (3 to 5/ 12), and positive (≥ 6/ 12) according to the number of animals with subclinical hypocalcemia.

Results: So far, 348 samples from 29 herds have been analyzed. Overall, the prevalence of subclinical hypocalcemia in dairy cows was 36.8%. Prevalence increased with age and was present in 7.9%, 23.3%, 36.8%, and 55.1% of 1st, 2nd, 3rd, and ≥4th lactation animals, respectively. There were 5, 15, and 9 herds classified into negative, borderline, and positive for subclinical hypocalcemia, respectively. The number of animals with subclinical hypocalcemia in a herd sample ranged from 1 to 9 out of 12 (8.3 to 75.0%).

Conclusions: Preliminary results indicate that the prevalence of subclinical hypocalcemia in German dairy herds is high. Subclinical hypocalcemia is considered a gateway disease in transition dairy cows leading to other clinical diseases such as metritis and displaced abomasum. Therefore further research is warranted to estimate the effect of subclinical hypocalcemia on health, milk production and reproductive performance on a cow and a herd level.

New mineral -vitamin blocks for dairy cows ration integrating utilizing domestic raw materials

Aiga Trupa¹ Uldis Osisis¹

¹Latvia university of Agriculture, Jelgava, Latvia

Objectives: Animal nutrition is often faced with scarcity of mineral substances in the feed ration, causing metabolic disorders and significantly affecting the animal's health and productivity. The objectives of the study was to investigate the new mineral substances and vitamin blocks for dairy cow ration integrating utilizing domestic raw materials.

Materials and Methods: For the research Latvian Brown cows were selected and assigned by the analogy principle to two treatments groups (n=2x12). Lactation dairy cows were included in the trial in the initial lactation phase with the average milk yield of 20.33 kg per day, fat content 4.03% and 3.64% protein content in milk. During the experiment the total mix ration (TMR) contained: 20 kg (36.12%), maize silage, 16 kg (45.15%) cereal grass- clover silage, 2 kg (4.51%) hay (cereal grass-clover), 4 kg (9.03%) concentrated feed mixture (rape oil-cake-barley meal), 2 kg (4.53%) protein concentrate, 0.1kg (0.22%) mineral premix ViloMin 9/6, 0.1 kg (0.22%) sodium chloride and 0.1 kg (0.22%) sodium carbonate. According to the investigation method, the control group of cows was fed traditionally complete feed rations, but experimental group in the feed ration were included for each cow individually mineral and vitamins complementary blocks. The forage analyses were made in the accredited laboratory of chemical analyses of the Latvia University of Agriculture, according to the EU ISO 6496 standard. Milk analyses were made of a/s "Siguldas CMAS" the milk control laboratory using Milkosan equipment according to ISO 9622:1997 standard. The data mathematical processing was made applying the program MS Excel. Credibility of results was tested by t-Test.

Results: Productivity indicators analysis showed, that within 151 days of study the experimental group had a milk yield of 19.1 kg ECM per day higher than in the control group. During the research, milk composition by its fat and protein content in the experimental group was increased by 0.16% and 0.12% compared with the control group (p <0.05). The research demonstrated the favorable influence of complementary mineral-vitamin blocks on the decrease of somatic cell count in milk: somatic cell count decreased by 202.07 thsd. ml⁻¹ in the experimental group and 250.77 thsd. ml⁻¹ in the control group cows. The economic effectiveness of feeding out the mineral-vitamin block was positive. Each experimental group of cows, which was fed on the complementary mineral-vitamin blocks gave on 2.94 euro higher milk output than their counterparts in the control group.

Feeding, growing and finishing Friesian calves with diets supplemented with soybean oil and vitamin E

Rui Fortunato¹ Teresa Madrigal² José Lemos³ Rui Bessa³ Almudena Cabezas⁴ Vicente Jimeno⁴

¹Technical, Rações Zêzere, S. A., Ferreira do Zêzere, Portugal, ²Facultad de Veterinaria, Universidad Complutense de Madrid, Madrid, Spain, ³Faculdade de Medicina Veterinária da Universidade de Lisboa, Lisboa, Portugal, ⁴Escuela Universitaria de Ingeniería Técnica Agrícola,

Universidad Politécnica de Madrid, Madrid, Spain

Objectives: In recent years it has been held a lot of research on the manipulation of the fatty acid composition of intramuscular fat of beef through the supplementation of diets with polyunsaturated oils. However, little is known about the effects of such supplementation on sensory quality of beef, and it is possible that the greater susceptibility to oxidation of the more unsaturated intramuscular fat may result in changes in color and organoleptic properties.

Materials and Methods: In this work we tested the effect of supplementing feed for finishing calves with soybean oil and vitamin E on growth parameters and sensory quality of meat. We used 63 Friesian castrated male calves with 6 months of age, randomly assigned to three treatments (a pen per treatment with three replicates) fed with compound feed and straw ad libitum for 60 days before slaughter. The compound feed included a supplement of 4% saponified palm oil (T1), 4% soybean oil (T2) and soybean oil 50mg/kg + Vitamin E (T3). Experimental feeds were formulated to be isoenergetic and isonitrogenous. During this period, the animals always had free access to good-quality water and straw.

Results: The animals of treatment T1 and T2 had a lower feed efficiency than animals from T3 (5.62 and 5.47 vs 5.22 kg of feed /kg BW, respectively), the same effect was observed in ADG. The dietary treatments had a significant effect on meat characteristics. Meat from animals of T2 had a significantly higher pH value, whereas T3 produced a meat with values significantly higher than the other treatments in both the L* value (37.9 vs. 34.5 and 35.2 for T3, T1 and T2, respectively) and the b* value (3.83 vs. 2.53 and 2.41 for T3, T1 and T2 respectively). However, supplementation with soybean oil and vitamin E did not affect the shear force value of meat there was a huge difference in shear force due to ageing. The meat of animals T3 had a significant higher amount of fatty acids C20:5 n-3 EPA (1,4 vs 1,2 and 1,0 mg/100g in T3, T2 and T1 respectively) and more C22:5 n-3 (6,2 vs 5,8 and 5,4 mg/100g in T3, T2 and T1 respectively) which result in a significant difference in the content of n-3 fatty acids (11,7 vs 14,8 and 16,2 for T1, T2 and T3 (P=0,0048)). The evaluation by the tasting panel showed no preference, only a very high global acceptance of meat of all treatments.

Conclusions: Our results suggest that supplementation of diets for growing / finishing calves with 4% soybean oil allows for higher feed efficiency and that supplementation with soybean oil + Vitamin E 50 mg/kg also allows for a meat with a lighter color, usually appreciated by consumers, without affecting its tenderness.

The effect of injectable trace mineral supplementation on the semen quality of bulls.

Luc Durel¹Martin FERREIRA²:D. HOLM³Louisa V. WYK²Clancy ROSE¹

¹VIRBAC SA, CARROS, France, ²VIRBAC RSA, CENTURION, ³Faculty of Veterinary Medicine, University of Pretoria, Onderstepoort, South Africa

Objectives: Reproductive performance of cattle is the main profit driver of most cattle farms around the world. While reproduction may be influenced by several factors, correct mineral balance is crucial to the reproductive performance of all species, including cattle and sheep. The aim of this study was to assess the impact of a commercially available

trace mineral injection containing 40 mg/mL Zn, 15 mg/mL Cu, 10 mg/mL Mn and 5 mg/mL Se (Multimin Cattle, Virbac SA) on the sperm and semen characteristics of high genetic merit Brahman and Simmentaler bulls managed by the Faculty of veterinary Medicine, University of Pretoria (South Africa).

Materials and Methods: Experimental animals consisted of 5 Brahman and 5 Simmentaler 4-6 year old confirmed bulls with recorded data on spermatogenic function. Animals were purchased from commercial operations and then brought to the experimental site. All animals were in good condition and free of reproductive and other diseases including trichomoniasis, vibriosis, brucellosis, bovine tuberculosis, EBL and BVD (PI). Animals were fed a balanced ration which was supplemented in trace minerals with a commercial mineral mix prior to, and throughout the study period. Body condition scores (BCS) and body weight ranged from 3.5-4 and 420-750 kg, respectively. On day D0, animals were randomly allocated to either group M (treated) or group C (Control) and each group consisted of 2 Brahman and 3 Simmentaler bulls. Group M animals were dosed subcutaneously with the trace mineral injection at a rate of 1 mL/50 kg while group C animals received a sterile saline injection at the same dose rate. Animals were followed for 3 months after the initial injection. Semen was collected twice a week and immediately analysed to assess its quality (volume and aspect, spermatozoa (SPZ) activity, SPZ defects). Mean concentration of spermatozoa (SPZ), total volume of semen collected over the study period, total of SPZ collected, mass motility score (MMS) and SPZ individual motility, percentage of motile SPZ and percentage of SPZ with no morphological defects were reported. The ejaculate was the statistical unit and threshold of statistical significance was set to 0.05.

Results: Animals with poor MMS (<2) or a very low proportion of motile SPZ (<70%) would be excluded from commercial artificial insemination operations. Thus one animal was withdrawn from group C (all ejaculates MMS=0, except one) and one animal was excluded from group M (motile SPZ ranging 0-39%, all time points). Spermatozoa concentration was numerically higher (t-test, P=0.077) in Group M than in Group C. However, the proportion of ejaculates with more than 1.2x10⁹ SPZ/mL was significantly higher (Chi-2, P=0.038) in group M. Proportions of ejaculates with more than 2.0x10⁹ SPZ was also numerically higher in treated animals (Chi-2, P=0.095) than in untreated controls. Total volume of semen collected over time did not differ between groups but total SPZ collected during the study period was numerically higher in Group M than in group C. Between groups, the MMS did not differ (range 0-5, cut-off: 2, Chi-2). Proportions of ejaculates with more than 70% of motile SPZ also did not differ (Chi-2, P=0.417). Proportions of ejaculates with more than 70% of morphologically normal SPZ did not differ but the proportion of ejaculates with more than 10% of SPZ with nuclear defects was significantly lower (Chi-2, P<0.01) in group M animals than in group C.

Conclusions: Injection of trace minerals in advance of the semen collection process increases the proportion of ejaculates with a high concentration of SPZ. A positive trend was also observed for total SPZ collected over the study period (which is of importance for the production of artificial insemination straws). No differences have been reported in MMS and SPZ motility. Injection seemed to have a positive effect on the SPZ nucleus but impact of the treatment on SPZ physiology requires further investigation.

Comments: This study was funded by Virbac

Outbreak Of Polioencephalomalacia In A Sheep Flock In Northeastern Brazil

Antonio Câmara¹, Joseney M. Lima², Ivana Cristina N. Gadelha², José Renato J. Borges¹

¹Hospital Escola de Grandes Animais da Granja do Torto, Universidade de Brasília, Brasília, ²Universidade Federal Rural do Semi-Árido, Mossoró, Brazil

Objectives: Polioencephalomalacia (PEM) is a neurologic disorder of ruminants characterized by necrosis of the cerebral cortex. Clinical signs include blindness, ataxia, and sometimes recumbency with seizures. The present work aimed to report the clinical, laboratorial, and pathological findings of an outbreak of PEM in sheep from Rio Grande do Norte state, Northeastern Brazil.

Materials and Methods: During anamnesis the rancher stated that seven days previously seven sheep showed ataxia, stiff gait, and blindness evolving to lateral recumbency in approximately 5-7 days. The sheep were raised in a confinement system with access only to triturated soybean shells in the past month. Two sheep already died and two severely affected sheep were presented to the Veterinary Hospital. Clinical examination, hematological profile and cerebrospinal fluid analysis were performed. During hospitalization, the two remaining sheep died and all four sheep were necropsied.

Results: Clinical examination revealed lateral recumbency with pedaling, dehydration, grinding of the teeth, nystagmus, blindness, dilated pupils, tachycardia, and ruminal hypomotility. This two sheep and four other animals with initial signs were treated with thiamine and dexamethasone; four with initial signs recovered and the other two died. Hematology and cerebrospinal fluid analysis showed no alterations for the specie. Moderate cerebral edema was observed at necropsy. The main histopathological changes were in the cortex of occipital, temporal, parietal and frontal telencephalic lobes. Microscopic cortical lesions included segmentar laminar necrosis, spongiosis, swollen of vascular endothelial nuclei, nuclear picnosis, and mild infiltrate by neutrophils and eosinophils. In this flock, PEM was caused by the prolonged ingestion of soybean shells as the only food available. This dietary management increased the population of thiaminolytic microorganisms. Thiaminase can be the result of bacterial production that is associated with high-concentrate feeds, and it can be found in certain plants or secondary to drug usage.

Conclusions: The authors reiterate the necessity of more awareness by the ranchers in providing good quality roughage for livestock, and thus minimizing the frequency of diseases related to high-concentrate feeds.

The Biogenic Amine Gaba In Grass Silages Part 2 The Influence On Dairy Herd Health And Performance. Clinical Case Documentation

Klaus Eicken¹, Henner Scholz², Winfried Heimbeck³, Claudia Parys³, Manfred Coenen⁴

¹Dairy Practice, Dairy Practitioner, D 26939 Ovelgönne, ²Former Head of Clinic for Cattle Diseases, School of Veterinary Medicine, Hannover, ³Evonik Nutrition & Care, Hanau, ⁴Institute of Animal Nutrition, Veterinary University, Leipzig, Germany

Objectives: Feeding cattle grass is a high quality basic raw material. During ensiling, a marginal to strong true protein breakdown can occur mainly during the first 24 - 48 hours after covering the silo with the plastic (Muck and Pitt, 1993). Through bad fermentation conditions the formation of not desired products, e.g. GABA, is preprogrammed. In the following clinical case documentation, the influence of a GABA intake with the grass silage of approx. 100 g /cow/day over a period of 120 days and the consequences for health and performance of the dairy herd are described.

Materials and Methods: Since approx. 1996, an unspecific disease with severe problems, high incidence of ill cows and total losses, was observed in several dairy farms in Lower Saxony near the German North Sea coast. This disease was independent of good or bad farm management. As an example, the typical situation of one of these farms is described as follows:

- 1.) The dairy farm was well managed
- 2.) The cattle were housed in modern barns
- 3.) Whole cattle number: 120 dairy cows, nearly 120 heifers and calves
- 4.) Milk yield: 7928 kg, milk fat: 339 kg (4.28%), milk protein: 265 kg (3.34%)
- 5.) Initially good herd health
- 6.) The ration for the dairy cows (day 1- 120) consisted of
 - 6.1) Grass silage (first cut), obviously in good quality approx. 10 kg DM/cow/day (laboratory test results see below)
 - 6.2) Maize silage approx. 3 kg DM/cow/day
 - 6.3) Concentrated feed approx. 6-8 kg/cow/day (corresponding to the milk yield)
 - 6.4) Special concentrated feed 2 kg/cow/day
 - 6.5) Mineral mix 0.2 kg/cow/day

Laboratory test of the first cut grass silage: dry matter g/kg – 361, crude protein (cp) g/kg - 213, true protein (tp) g/kg – 79 (tp in % of cp 37,0), pH – 5,7: "result good". As the GABA concentration in the grass silage first cut seemed to be very high, we did 4 analysis (Evonik Nutrition & Care, Hanau) showing 10 g/kg DM on average. The resulting intake of GABA was approx. 100 g cow/day.

Results: Since mid of October (day 70-75 after starting the grass silage intake), the herd health was reduced remarkably and changed for the worse with the following clinical signs:

- | | |
|--|---------------------------------|
| 1.) Behavior: | weary |
| 2.) Movement | painful and slow |
| 3.) Going into the milking parlour | unwillingly |
| 4.) Milk yield: | reduced |
| 5.) Feed intake: | reduced |
| 6.) Weight: | loss |
| 7.) Manure: | dark-green, creamy-watery |
| 8.) Downer cow syndrome: (after parturition) | increased (ten to twelve weeks) |
| 9.) Displacement of the abomasum: | increased |
| 10.) Placenta retention: | increased |
| 11.) Mastitis and high SCC: | increased |
| 12.) Aggravation of "simple" diseases | |
| 13.) Treatment of diseases: | with lower success |
| 14.) Loss of cows: | increased |
| 15.) Sudden death: | several cows |

At day 120 (mid of December) after starting feeding the first cut grass silage (mid of August), the ration was changed to a second cut grass silage with GABA concentrations of 3.2 g GABA/kg DM (average n= 4). So, the total GABA intake was reduced from 100 g/cow/day (first cut) to

32 g/cow/day (second cut). Approx. 4-6 weeks after the change of the grass silage in the ration the dairy herd appeared completely changed with markedly increased health improvement. Only the critically sick fallen cows had no chance to recover.

Conclusions: Decreased true protein and increased GABA concentrations could be observed in Northern Germany during the last 20 years. In our case documentation, there was an intake of nearly 100 g GABA/cow/day for 120 days. Based on our experience over years, we can postulate that the intake of 40-45 g GABA/cow/day will be tolerated. But there is an enormous risk for disease in high yielding cows if the total GABA intake exceeds >45 g/day for a longer period (at least > 8 weeks).

Nutrition & Metabolic Diseases

P01-001-040

The effect of addition anionic salt in prepartum period in cows on chemiluminescence of PMN cells.

Hanna Markiewicz^{1,2} Zdzisław Gajewski¹ Wiesław Krumrych² Ryszard Gouda²

¹Department of Large Animal Diseases with Clinic, FACULTY OF VETERINARY MEDICINE WARSAW, UNIVERSITY OF LIFE SCIENCES, WARSAW, POLAND, Warsaw, ²Department of Immunobiology, Institute of Experimental Biology, Kazimierz Wielki University in Bydgoszcz, 85-064 Bydgoszcz, Poland

Objectives: It is known, that the periparturient period is characterized by immunosuppression. In state of acid-base imbalance there is also observed a decrease of immunity.

The purpose of added anionic salt to the ration of dry cows before calving is to achieve a state of compensated metabolic acidosis. The aim of this study has been to evaluate the impact of addition anionic salt on PMN cells chemiluminescence (CL) level in last three weeks before parturition.

Materials and Methods: The study was conducted on 20 Polish HF cows before the third lactation. All the cows received the same TMR but 10 of them (experimental group) got extra 100g anionic salt (MgSO₄·7H₂O)/cow/ a day for three weeks before parturition.

The blood samples were taken from their tail veins in -3, -2 and -1 week precalving. At the same time there were collected urine (by catheter) for urinary pH determination. The samples were collected into tubes containing K₂EDTA and lithium heparin. In whole blood there were determined level of chemiluminescence and haematological indices (BioOrbit 1251 Luminometer; ABCVet, Horiba ABX, France). Blood gas and pH were also analysed (Analyser 248 Ciba-Corning).

Results: Before parturition anionic salt supplemented cows urine pH was lower than control cows. Also blood pH the experimental group was lower in comparison with the control group. Oxidative metabolism of PMN cells, expressed as the level of chemiluminescence, was similar in the two groups. The level of chemiluminescence before parturition was determined by function of time. The main way to induce phagocytic activity was receptor pathway – CL induced by opsonized zymosan. There was no CL response to extrareceptor stimuli.

Conclusions: The addition of the anionic salt had no effect on the level of spontaneous and induced chemiluminescence. There was observed a tendency to decrease the level of CL but the differences were not statistically crucial.

Nutrition & Metabolic Diseases

Effects of monensin and essential oils on fat mobilization and ketosis in dairy cows in the transition period

György Szura^{1,2} Caroline Drong² Claudia Raschka¹ Ulrich Meyer² Dirk von Soosten² Gerhard Breves³ Sven Dänicke² Jürgen Rehage¹

¹Clinic for Cattle, University of Veterinary Medicine Hannover, Foundation, Hannover, ²Institute of Animal Nutrition, Friedrich-Loeffler-Institute, Braunschweig, ³Institute for Physiology, University of Veterinary Medicine Hannover, Foundation, Hannover, Germany

Objectives: Ketosis as a consequence of negative energy balance in early lactation is a frequent health disorder in dairy cows. In particular over-conditioned cows are at risk of ketosis. The ionophore antimicrobial agent monensin alters ruminal flora in favor of propionate producing microbes and is approved for prevention of ketosis. Recently it has been reported that essential oils distilled from plant material have similar effects and may provide an alternative to monensin. The aim of this study was to compare effects of monensin and essential oils on fat mobilization and ketosis in dairy cows during the transition period.

Materials and Methods: The study was performed at the Friedrich-Loeffler-Institute (FLI), Braunschweig, Germany. 60 German Holstein cows were allocated at first to two groups according to their body condition (BCS). Cows with low BCS (LC; n=15, mean BCS 2.77 ± 0.14 (± SD)) were used as positive control and received diets with 20% concentrate ante partum (a.p.). Cows with high BCS (n=45, mean BCS 3.95 ± 0.08 (± SD)) were subdivided to form the negative control (HC/C, n=15), or to receive either a monensin controlled-release capsule (HC/MO, n=15) or a blend of essential oils (HC/EO, n=15) and were fed diets with 60% concentrate proportion a.p. Postpartum (p.p.) all groups were initially supplied with 30% concentrate, which constantly was increased to 50%. For feeding automated weighing troughs were used. Cows were studied from d-42 a.p. until d56 p.p.. Blood samples were collected in weekly intervals from all cows (analysis of glucose, beta-hydroxybutyrate (BHB), fatty acids (NEFA)) and sonography was performed to assess subcutaneous and total abdominal fat mass in a subgroup of eight cows of each group on d-21, d7, d21 and d56 relative to parturition. Also dry matter intake (DMI), milk yield, milk constituents and energy balance were recorded. Results were statistically evaluated in a mixed model with group, time and interactions as fixed effects and cow as random effect with Tukey test for multiple comparisons of means (SAS package 9.3).

Results: Mean DMI was lowest before and highest after parturition in the LC- compared to HC-groups (group*time: p < 0.001). Treatment had no significant effects on milk yield and 4%fat corrected milk yield. In average energy balance was significantly higher in HC-groups than in the LC group before parturition, which was reverse after parturition (group*time: p < 0.001). After parturition mean blood NEFA were significantly lower (group*time: p = 0.013) and BHB concentrations higher in the LC group than in HC-groups. However, from HC cows those of the HC/MO-group presented mean BHB levels lower than of cows of HC/C and HC/EO and numerically lower than of cows of the LC-group (group*time p = 0.008). Loss of subcutaneous and total abdominal fat mass assessed in kg/day after parturition revealed no treatment effects.

Conclusions: Mean blood BHB level was significantly reduced in monensin treated cows although monensin revealed no effect on lipomobilization after parturition according to blood NEFA concentrations and daily adipose tissue weight changes. Results suggest that a monensin controlled-release capsule could promote a more effective hepatic or extra hepatic NEFA or extra hepatic BHB utilization in dairy cows after parturition, thus reducing the risk of subclinical ketosis, whereas essential oils failed to produce a comparable effect.

Nutrition & Metabolic Diseases

Association Of Virginiamycin And Monensin Mitigates The Rumen Lactic Acidosis Effects In Cattle

Francisco L. C. OLIVEIRA ¹Rejane S. SOUSA ¹Juliana A. A. SANTOS ²Carolina A. S. C. ARAUJO ¹Christopher R. WHITE ³Bruno T. B. HONDA ³Ana L. C. O. GALVÃO ⁴Clara S. MORI ¹Antonio H. H. MIVERVINO ⁵Enrico Lippi ORTOLANI ¹

¹Department of Clinical Science, ²Nutrition and Animal Production, Faculty of Veterinary Medicine - University of Sao Paulo, ³Phibro Animal Health, ⁴São Paulo University, São Paulo, ⁵Federal University of Western Pará - UFOPA, Santarém, Brazil

Objectives: Rumen lactic acidosis (RLA) is a common disease in feedlot cattle. For prevention of this illness some dietary ionophores and antibiotics are used, mainly monensin (M) and virginiamycin (V). This experiment was carried out to check, by the first time, the effects of preventive use of dietary V + M on an experimental RLA in cattle.

Materials and Methods: An Official Brazilian Animal Ethics Commission approved this protocol, previously. Twelve yearling Nellore heifers were rumen cannulated and fed for one month with a 75% roughage and 25% concentrate diet according to their 2.5% body weight. Six heifers received daily 250 mg V and 300 mg M (V+M) in the diet and the same number kept as a control (C). An experimental RLA was induced in all animals by infusion of different amount of sucrose, into the rumen cannula, according to a formula based on a corrected metabolic weight. For the next 18 h some rumen parameters (pH; L- Lactate level; titratable acidity and redox potential), hematological (plasma volume deficit PVD) and clinical picture were followed. For complete recovering many animals needed, at the 18h, a treatment based on withdraw of all rumen fluid and replacement with healthy rumen fluid and water, and intravenously infusion of large amount of Lactated Ringer Solution. The distribution of all data was evaluated using the Kolgomorov-Smirnov test followed by repeated measures modelling with PROC-MIXED and coefficient of determination (R²) in the SAS.

Results: Rumen pH and L-Lactate levels were lower and higher, respectively, at the 3rd, 6th and 18th h in the control group (P= 0.019). Both titratable acidity (12th and 18th h), and redox potential (3rd, 6h, and 12th) were higher in the control group (P = 0.03). The R² for rumen pH with the following variables L-Lactate level, redox potential and titratable acidity were 0.91, 0.96 and 0.87, respectively. These results suggested that the principal acid produced in this induction was L-Lactate and somehow V+M decreased the production of this acid probably by interference with Lactobacillus sp population growth, most important rumen lactate producer, since this bacteria requires very high rumen redox potential to growth. There was a tendency (P= 0.1) for the PVD to be higher in the control group at the 18th h, suggesting a more developed degree of dehydration. Most of the cattle (4/6) of the control group exhibited pronounced clinical signs as compared to the V+M group (1/6), mainly shown by severe dehydration (sunken eyes and coldness in the extremities), recumbency, mental depression that required rapid treatment for complete recovery thereafter.

Conclusions: This experiment showed that V+M used preventively could mitigate the risk of a very severe RLA by decreasing the production of rumen lactate, and the rumen redox potential and thus avoiding a very sharp drop in the rumen pH that could cause harmful clinical signs.

Effect of duration and temperature during the delivery of bovine urine samples to the analytical laboratory on metabolic parameters assays

Barbara Galmiche ¹Catherine Garnier ¹Laurent Alves De Oliveira ^{2,3}

¹IDOLAB, ²Campus vétérinaire de Lyon, VETAGRO-SUP, Marcy l'Etoile, ³UMRH, INRA, Theix, France

Objectives: Urine samples collected in bovine medicine are often exposed to a range of environmental conditions prior to analysis in a laboratory. The stability of the molecules in the bovine urine is poorly understood. The aim of this study was to determine the stability of urine specimens exposed to a range times and two storage temperatures.

Materials and Methods: Urine samples were taken with a urinary catheter in 10 lactating Montbeliarde cows in one farm, 1.5 hours after the morning diet distribution. The samples were immediately placed in a cooler box, protected from light, and sent to the laboratory. For each cow, the sample is divided into 17 aliquots. one aliquote was centrifuged and analyzed in the 3 hours after collection (D0) as controls. 8 aliquots, were placed in a refrigerated chamber at 4°C and 8 aliquots, left at room temperature (25°C). All the samples were kept sheltered from the light. The day D1, D2, D3, D4, D7, D8, D9, D10, one aliquote stored at room temperature and one kept cool tube were centrifuged and analyzed. The analysis method used was a enzymatic colorimetric method with an automated biochemistry analyser (JEOL Biomajesty 6010 with Biomérieux, Diasys, Diacron and Randox kits).

Statistical analysis was performed with the Excel © software. For each biochemical parameter, outliers were removed by the Grubbs test. For each pair number storage day / storage temperature and each parameter, the averages of the 10 cows was compared with the average to D0 by a Student's t test for paired data if normal distribution (checked by Shapiro-Wilk test) and variance equal (verified by Cochran's test) or by test of Wilcoxon signed rank in other cases. The results of stored samples were considered to be different from the value on D0 (reference) if the difference between average of stored samples and D0 average was greater than the measurement uncertainty or if p> 0.05.

Results: Assay results are identical to the D0 value during the numbers of days (d) following : (for samples stored at 4°C and 25°C respectively) ; calcium 10 d, 10 d ; chloride 10 d, 10 d ; total carbon dioxide 7 d, 7 d ; creatinine 10 d, 10 d ; magnesium 4 d, 4 d ; Phosphate Inorganic 2 d, 2 d ; Potassium 10 d, 10 d ; Sodium 10 d, 10 d ; Urea 10 d, 10 d.

Our results show a stability of creatinine much longer than that reported by Saliman et al in 1986, against we find the same duration stability for urea.

Conclusions: The storage temperature has no effect on the duration of biochemical parameters stability in urine until 10 days.

The stability of biochemical specimens is very long, it reached 10 days except for Phosphate Inorganic (2 d.) and to a lesser extent magnesium (4 d.).

The duration stability in urine is better than in blood except for Phosphate Inorganic and magnesium. These results show a very good stability of urine parameters in cattle. The use of this biochemical assays should not be limited even if the delivery times in the laboratory is several days.

Injectable Mineral supplementation of phosphorus and selenium in addition to oral free-choice mineral mixes in young Nelore cattle in Brazil.

Luc Durel¹Bruno SIVIERI DE LIMA²Raphael ALVES VIOTTI²Renan SOUZA BARROS²Clancy ROSE¹

¹VIRBAC S.A., CARROS, France, ²VIRBAC Saúde Animal, SAO PAULO, Brazil

Objectives: In Brazilian beef cattle operations, delivery of free-choice mineral mixes is the most common way of supplementing animals with minerals. However, in grazing animals, free-choice oral supplementation poses several problems which reduce mineral bio-availability, meaning that animals often do not get adequate amounts to meet their minimal requirements, as recommended by the NRC. The aim of this study was to determine the effect of a single injection of sodium glycerophosphate (1.40 g/10mL), sodium phosphate (2.01 g/10mL) and sodium selenite (0.024 g/10mL) (P-Se) (FOSFOSAL®, Virbac Saúde Animal, Brazil) in fast growing, pasture raised cattle.

Materials and Methods: Four distinct experiments were performed in three Brazilian beef operations located in Itapetininga (São Paulo), Santa Rita do Pardo (Mato Grosso do Sul) and Caceres (Mato Grosso). Experimental animals consisted of 256 mixed sex Nelore breed cattle. Three experimental groups consisted of all male animals, while one experimental group contained equal distribution of both sexes. The average age of animals ranged from 7 to 12 months within groups. Across all operations, animals grazed predominantly *Brachiaria decumbens* pastures with ad libitum access to free-choice oral mineral supplementation, in accordance with the normal management practices of the farms. In each experiment, animals were randomly allocated into two groups of equal size and treated according to body weight with a single subcutaneous injection of either a single injection of P-Se (group F) or sterile saline (group C) on Day 0. Both groups of animals were maintained on the same pasture under the same conditions and dietary changes during the study period. All animals also received a routine antiparasitic treatment (ivermectin) at the beginning of the study. The study period lasted approximately one month. Animals were weighed on Day 0 and again on the last day of the study. Individual Average Daily Gains (ADGs) were calculated in kg/day. Statistical analysis (t-test) was performed on group ADG using BioSta TGV.

Results: Animals were weighed between days 29 to 38. In Itapetininga(1), Itapetininga(2), Santa Rita do Pardo and Caceres reported ADGs(±sd) were 0.356(±0.173) vs. 0.467(±0.186), 0.054(±0.169) vs. 0.302(±0.180), 0.446(±0.294) vs. 0.605(±0.256) and -0.058(±0.409) vs. 0.046(±0.193) for Groups C and Groups F, respectively. In all but one experiment, differences were significant (p<0.05). Further investigations are needed to confirm these results for longer periods in this class of stock and also to determine if other stock classes (heifers, cows and bulls) could benefit from a similar approach.

Conclusions: While it is essential to have an efficient oral mineral supplementation program in place to avoid clinical deficiency, at the herd level, there may be some benefit in supplying minerals via an alternate route, namely via injection at strategic times of the production cycle. Under standard Brazilian grazing conditions, providing injectable P-Se to young, growing Nelore cattle in addition to a free-choice oral mineral supplement looks very beneficial, resulting in higher ADGs in treated animals compared to controls animals. In 3 experiments out of 4, differences in mean ADGs between treated and untreated animals were significantly different.

Comments: Authors greatly acknowledge staffs of the farms.

Effect Of An Injectable Supplement Containing Vitamin E And Selenium Pre-Calving On The Postpartum Response To Glucose Tolerance Test In Dairy Cows

Angel Abuelo^{1,2}Victor Alves-Nores¹Joaquin Hernandez¹Rodrigo Muiño³Jose L. Benedito¹Cristina Castillo¹

¹Department of Animal Pathology, University of Santiago de Compostela, Lugo, Spain, ²Graham Centre for Agriculture Innovation, NSW Department of Primary Industries and Charles Sturt University, Wagga Wagga, Australia, ³Centro Veterinario Meira, Meira, Spain

Objectives: Dairy cows undergo a period of insulin resistance (IR) following calving, but the mechanisms causing IR are not fully understood in cattle. In human type II diabetes, there is strong evidence that oxidative stress (OS) plays a causative role in the development of IR, and antioxidant supplementation can be used to reduce its consequences. Transition dairy cattle experience OS, and a significant association between OS and whole-body insulin sensitivity has been recently reported during this period. Hence, this trial aims at establishing whether antioxidant therapy enhances the response to glucose tolerance tests in early lactating cattle.

Materials and Methods: Ten close-up dry cows from the same herd were randomly allocated to one of the study groups. Two weeks prior to expected calving, the treatment group received an IM injection (Selevit adultos, Laboratorios SYVA, Leon, Spain) containing 6 mg/kg of DL-tocopherol acetate (vitamin E) and 0.06 mg/kg of sodium selenite, whereas the control group was sham injected with isotonic saline. Three to 7 days after calving cows in both groups underwent a glucose tolerance test (GTT). For the analytes glucose, insulin, non-esterified fatty acids (NEFA) and β-hydroxybutyrate (BHB) the following parameters were calculated and compared between groups with the Mann-Whitney U test: areas under the curve (AUC), peak and nadir concentrations and elimination rates.

Results: No differences between groups were found for the concentrations of the metabolic markers studied either at the time of group allocation or at the basal GTTs measurements. With regards to the response to the GTTs, differences between groups were found for the AUC for glucose (P=0.009), insulin (P=0.043) and NEFA (P=0.041), along with the elimination rates of NEFA (P=0.047) and insulin (P=0.008). A trend to significance was found for the glucose elimination rate (P=0.076). These results showed an improved energetic metabolic response to GTTs in the animals supplemented with vitamin E and Selenium pre-calving, with an increased whole-body insulin sensitivity. Thereby implying that oxidative stress plays a causative role in post-parturient insulin resistance in dairy cattle and that antioxidant therapy might be beneficial for ameliorating the harmful consequences of a prolonged IR state.

Conclusions: Parenteral supplementation with vitamin E and selenium two weeks before calving improved the animals' response to glucose tolerance tests during the first week after calving, showing higher insulin sensitivity. Hence, it is concluded that oxidative stress plays a causative role in the development of IR in dairy cattle, and that antioxidant therapy can ameliorate the detrimental effects of prolonged IR.

A meta-analysis of lasalocid effects on rumen measures, beef and dairy performance, and carcass traits in cattle

Helen Golder¹Ian J. Lean^{1,*}

¹Scibus, Camden, Australia

Objectives: The objective of this study was to evaluate the effects of lasalocid feeding on rumen measures, beef and dairy performance, and carcass traits in cattle, using meta-analytic methods to describe its impact and explain heterogeneity of responses among studies.

Materials and Methods: Literature searches were performed in PubMed, Google Scholar, and ISI Web of Knowledge using the following search: (Lasalocid OR Bovatec) AND (cattle OR cows OR feedlot OR calves OR dairy OR beef). Studies were included if they met the following criteria: were full manuscripts from peer-reviewed English language journals, evaluated use of lasalocid supplementation against a control, described randomization process, had a randomized controlled trial design only, animals studied were weaned cattle, they included replication of treatments, sufficient data to determine the effect size (ES), a measure of effect amendable to effect size analysis for continuous data (e.g. standardized mean difference, SMD); and a measure of variance (SE or SD) for each effect estimate or treatment and control comparisons. Only variables with a minimum of 6 comparisons were evaluated. Stata v. 11 (StataCorp. LP, College Station, TX) was used to analyze output variables by SMD and only random effects models were used. The difference between lasalocid treatment and control groups means was standardized using the SD of control and lasalocid treatment groups. The SMD estimates (ES and 95% CI) were pooled using both the DerSimonian and Laird and Knapp-Sidik-Jonkman methods for random effects models to evaluate the effect of study and displayed in forest plots. Heterogeneity was assessed using a chi-squared (Q) test of heterogeneity. Meta-regression analyses were used to explore the source of heterogeneity of response. The presence of publication bias was investigated using contour-enhanced funnel plots.

Results: Rumen measures were assessed using 10 studies (20 comparisons). Lasalocid increased total VFA and ammonia concentrations by 6.46 and 1.44 mM, respectively. Lasalocid increased propionate and decreased acetate and butyrate molar percentage (M%) by 4.62, 3.18, and 0.83%, respectively. Valerate M% and pH were not affected. Meta-regression found butyrate M% increased linearly with duration of lasalocid feeding (DUR; P = 0.017). When >200 mg/d was fed, propionate and valerate M% were higher and acetate M% was lower (P=0.042, 0.017, and 0.005, respectively). Beef performance was assessed using 31 studies (67 comparisons). Lasalocid increased ADG by 40 g/d, improved feed-to-gain (F:G) by 410 g/kg, and improved feed efficiency [FE; combined gain-to-feed (G:F) and inverse of F:G]. Lasalocid did not affect DMI. Heterogeneity in DMI was influenced by DUR (P=0.004) and linear effect of entry BW (P=0.011). Heterogeneity of ADG was influenced by the linear effect of entry BW (P=0.028). The FE (P=0.025) and F:G (P=0.015) improved linearly with dose, and entry BW >275 kg improved F:G (P=0.038). Carcass traits were assessed using 14 studies (25 comparisons). Lasalocid increased HCW by 4.73 kg, but not dressing percentage, mean fat cover, or marbling score. Heterogeneity of carcass traits was low and not affected by DUR or dose. Dairy performance was assessed using 7 studies (11 comparisons) but study power was relatively low. Lasalocid decreased DMI in TMR-fed cows by 0.89 kg/d, but had no effect on milk yield, milk components, or component yields. Dose linearly decreased DMI (P=0.049).

Conclusions: This work showed lasalocid improved ADG, HCW, FE, and F:G for beef production. These findings may reflect improved

energy efficiency from increased propionate and decreased acetate and butyrate M%. Large dairy studies are required for further evaluation of effects of lasalocid on dairy performance. These results allow producers, nutritionists, and veterinarians to make informed decisions on the inclusion of lasalocid in cattle diets.

P01-001-047

Impacts of a monensin capsule administered within thirty days of calving on health and milk production in lactating dairy cattle - a meta-analysis

Todd Duffield¹Thomas Erlacher²Geert Vertenten^{3,*}

¹Population Medicine, University of Guelph, Guelph, Canada, ²Elanco Animal Health, Vienna, Austria, ³Elanco Animal Health, Brussels, Belgium

Objectives: The objective of this project was to conduct a meta-analysis of research on the health and production effects of administration of a monensin controlled release capsule within thirty days of calving to provide a summary of expected effects and heterogeneity of response.

Materials and Methods: A database containing data from papers identified with a previous meta-analysis (Duffield et al, 2008) were utilized as a starting point for the data acquisition. A total of three additional papers were identified for inclusion beyond what was previously reported. In addition, the data from the European registration trial for the monensin controlled release capsule (Kexxtone™) was acquired for inclusion. Reported research needed to involve monensin delivery via capsule within thirty days of calving, treatments must have been randomly assigned and compared to an appropriate control group. A mean, number of animals per group, and some measure of dispersion must have been included.

Data was extracted for several outcomes including cow health (including clinical ketosis, displaced abomasum, metritis, mastitis, retained placenta), and milk production (yield, fat percent, protein percent). A meta-analysis was conducted on the extracted outcomes using Stata (Intercooled Stata V. 13.1, USA). Effect size estimates were generated using a standardized mean difference for continuous outcomes and relative risk for dichotomous variables. Heterogeneity and percentage of variation across studies due to heterogeneity were both tested in each model with appropriate statistics. If there was evidence of heterogeneity, a random effects model was used.

Results: There were a total of nine papers, 14 trials, 105 trial sites and 5876 cows available to evaluate the impact of the monensin controlled release capsule on health outcomes. Similarly there were also nine papers, 18 trials, 98 trial sites and over 6000 cows to evaluate the impact of the monensin capsule on milk production parameters. Across all studies, milk production was increased with the administration of the monensin capsule two to four weeks prior to calving (P=0.06), however, there was significant heterogeneity in the data (P=0.02), indicating that the response varied by trial. The analysis using weighted mean difference did show a significant increase (P< 0.05) of an average of 0.6 kg/day of milk yield for the first 3 to 4 months of lactation. There was no effect of the capsule on either milk fat percentage (P=0.36) or milk protein percentage (P=0.36).

Analysis of health outcomes indicated that administration of the controlled release capsule prior to calving significantly reduced the incidence of both Clinical Ketosis (RR=0.70, P<0.001) and Displaced Abomasum

(RR=0.80, P<0.001). The impact of monensin on retained placenta was not significant (P=0.16) but did have significant heterogeneity (P=0.02). There were no other significant findings for any of the other health outcomes.

Conclusions: In addition to the label indication of reduced incidence of subclinical ketosis, use of a monensin capsule prior to calving can be expected to reduce the incidence of clinical ketosis and displaced abomasum. In addition, an average of 0.6 kg/day increase in early lactation milk yield is expected, although this response varies between studies. The heterogeneity of response in milk yield is consistent with milk yield being associated with restoring milk production potential in high risk ketotic cows/herds. These benefits were found when administering prevention to all cows, thus responses would be expected to be better in high-risk cows.

Carcass characteristics and meat evaluation of Nelore cattle submitted to different antioxidants treatments

Tiago D. J. do Carmo¹Vanessa Peripolli²Candice B. Tanure²Maria Clorinda S. Fioravanti¹João Restle¹Liris Kindlein³Concepta McManus^{2,*}

¹Federal University of Goias, Goiania, ²University of Brasilia, Brasilia, ³Preventive Veterinary Medicine, Federal University of Rio Grande do Sul, Porto Alegre, Brazil

Objectives: This study aimed to evaluate the effects of supplementation with different natural antioxidants (zinc, selenium, vitamin E and selenium + vitamin E) on performance, carcass characteristics and meat quality of feedlot cattle fed with *Brachiaria* hay.

Materials and Methods: Forty Nelore cattle aged 24-36 months were used. Animals were fed *Brachiaria* brizantha hay and subjected to five treatments (control and four antioxidants: zinc, selenium, vitamin E and selenium + vitamin E). There were eight animals per group, each animal considered a replication. After 105 days feeding period, cattle were slaughtered at a commercial abattoir. After 24 hours in a cold room, the right halves of the carcasses were used to obtain pH values. The HH section was extracted between the 11th and 13th rib of the left half of each carcass, for determination of muscle, bone and fat percentage. Longissimus dorsi muscle samples, previously minced and homogenized, were used for determination of dry matter, ash and crude protein and fat content. The determination of the meat color was performed by CIEL*a*b* methodology using a colorimeter. Losses by thawing and in the cooking process, meat water retention capacity as well as shear force and lipid profile were evaluated in the Longissimus dorsi samples. Analysis of variance was carried out and the parameters with significant effect were compared by Tukey test, at 5% probability.

Results: There was variation in the carcass muscle percentage depending on antioxidant used. Selenium showed the lowest muscle percentage (66.61%) compared to the other antioxidants evaluated. However, there was no difference between treatments for bone, fat, comestible portion percentages and muscle: bone, muscle: fat and comestible portion: bone ratios with mean values of 16.85%, 14.70%, 82.99%, 4.06, 4.85 and 4.95, respectively. Neither brightness, red and yellow contents of the meat nor carcass pH were affected by treatments, with mean values of 29.29% of brightness and 6.31% of pH. For Longissimus dorsi muscle tenderness, losses on thawing and in the cooking process, there were no differences between treatments, with

averages 6.43 kg², 3.22% and 21.15%, respectively. There was variation in the fatty acid profile according to the antioxidant used. The fatty acids observed at the highest concentrations were myristic (C14:0, 14.15%), oleic (C18:1 n-9 cis /C18:1 n-9 trans, 13.73%), palmitoleic (C16:1, 13.47%), lauric (C12:0, 9.13%), eicosapentaenoic (C20:5 n-3, 8.91%), capric (C10:0, 8.43%) and palmitic acids (C16:0, 8.01%). Control, zinc and selenium treatments showed the highest levels of palmitic (C16:0) and stearic acids (C18:0) and lower levels of palmitoleic acid (C16:1). Higher amounts of palmitoleic (C16:1), heptadecenoico (C17:1), elaidic (C18:1 n-9 cis /C18:1 n-9 trans), linoleic (C18:2 n-6 cis/C18:2 n-6 trans 9) and DHA acids (C22:6 n-3/C24:1 n-9) and lower palmitic (C16:0) and stearic acids (C18:0) were observed for vitamin E and selenium + vitamin E treatments.

Conclusions: Supplementation of Nelore cattle fed *Brachiaria* brizantha hay with antioxidants did not influence carcass characteristics nor meat quality. However, vitamin E supplementation reduced the levels of omega 3, whereas supplementation with selenium + vitamin E promoted an increase in linoleic and palmitoleic acids, and reduced myristoleic acid, making the supplementation feasible due to the beneficial effects provided by these acids.

Phenotypic correlations between subclinical and clinical postpartum health disorders in Holstein cows

Vangelis Tsiamadis¹Nikolaos Panousis²Georgios Banos¹Maria Kritsepi-Konstantinou³Georgios Arsenos¹Georgios E. Valergakis¹

¹Laboratory of Animal Husbandry, ²Farm Animal Clinic, ³Diagnostic Laboratory, Faculty of Veterinary Medicine, School of Health Sciences, Aristotle University of Thessaloniki, Thessaloniki, Greece

Objectives: The objective was to estimate the phenotypic correlations between serum Ca, P, Mg, K and β-hydroxybutyric acid (BHBA) concentrations, body condition score (BCS) and several postpartum health disorders during the first 8 days after calving in Holstein dairy cows.

Materials and Methods: The study included 1,021 Holstein dairy cows (1 - 4+ lactations) in 9 herds. No herd used preventive measures for hypocalcemia. Clinical examination and blood sampling was performed on DIM 1, 2, 4 and 8. Clinical cases of milk fever (MF), retained fetal membranes (RFM), metritis (MET), mastitis (MAST), left/right abomasal displacement (LDA/RDA), ketosis (KET), and uterine prolapse (UP) were recorded on the same days. Recordings of involuntary culling (INVCULL) and death (DE) were also performed on the same days. Serum concentrations of Ca and Mg were determined with AAS, while P and K with biochemical and electrolyte analyzers. BHBA was measured with a spectrophotometer in samples of day 8. The final data set included 4,020 Ca, 4,019 P, 4,020 Mg, 3,792 K, 997 BHBA measurements and 4,064 clinical records. Macromineral-related traits defined as: subclinical hypocalcemia (SCHCa): Ca_s≤8.3 mg/dL; hypophosphatemia (HypoP): P≤4.2 mg/dL; subclinical hypomagnesemia (SCHMg): Mg≤1.8 mg/dL; hypokalemia (HypoK): K≤3.9 mEq/L; and hyperphosphatemia (HyperP): P≥7.80 mg/dL. Relevant phenotypic correlations during the first 8 days after calving were estimated with bivariate analysis using random regression and single record models. The analysis for Ca, Mg, P and K and the macromineral-related traits included 986 cows, which showed no obvious signs of MF (35 cows with MF were excluded). The analysis for the other health traits included all 1,021 cows.

Results: Serum Ca had low negative phenotypic correlations with BHBA, RFM, MET, LDA and DE (r_p : -0.09 to -0.18; $P < 0.05$), moderate negative correlation with MF (r_p : -0.32±0.03; $P < 0.05$) and low positive correlation with BCS (r_p : 0.11±0.03; $P < 0.05$). Serum P had low positive correlations with MAST (r_p : 0.12±0.03; $P < 0.05$) and UP (r_p : 0.08±0.03; $P < 0.05$). Serum Mg had low negative phenotypic correlations with RFM, MET and LDA (r_p : -0.07 to -0.15; $P < 0.05$) and low positive correlation with BCS (r_p : 0.14±0.03; $P < 0.05$). Serum K had low negative phenotypic correlations with BHBA, MF, RFM, MET, MAST and DE (r_p : -0.09 to -0.14; $P < 0.05$). SCHCa had low positive correlations with BHBA, HypoP, SCHMg, HypoK, MF, MET and LDA (r_p : 0.07 to 0.15; $P < 0.05$). HypoP had low positive correlations with SCHMg (r_p : 0.07±0.03; $P < 0.05$) and low negative with HyperP (r_p : -0.09±0.03; $P < 0.05$). SCHMg had low positive correlations with BHBA, HypoP, HypoK, RFM, HyperP and MET (r_p : 0.07 to 0.13; $P < 0.05$). HypoK had low positive correlations with BHBA, MF, MET, RFM and LDA (r_p : 0.07 to 0.13; $P < 0.05$). HyperP had low negative correlation with BHBA (r_p : -0.07±0.03; $P < 0.05$) and low positive with MAST (r_p : 0.07±0.03; $P < 0.05$). BSC had low negative correlations with BHBA and SCHMg (r_p : -0.07±0.03; $P < 0.05$). MF had low positive correlations with RFM and LDA (r_p : 0.07 to 0.11; $P < 0.05$) and moderate positive correlations with UP and DE (r_p : 0.18 to 0.19; $P < 0.05$).

Conclusions: The estimated phenotypic correlations showed a strong association between macromineral serum concentrations, subclinical health disorders, clinical diseases and recordings immediately after calving, emphasizing the necessity for integrated preventive management measures, regarding nutrition and housing.

Effect of Dietary Starch Levels In Early Lactation Dairy Cows

Hidir Gencoglu¹, Abdulkadir Keskin², Cagdas Kara¹, Ismail Cetin¹, Gulnaz Mecitoglu², Merve M. Efil¹, Duygu U. Kucuksen³, Abdulkadir Orman⁴, Yavuz Meral¹, Gulay Deniz¹, Ahmet Gumen², Erkan Sen¹, Ismet Turkmen¹

¹Department of Animal Nutrition and Nutritional Diseases, ²Department of Obstetrics and Gynecology, ³Department of Biochemistry, ⁴Department of Zootechnics, ULUDAG UNIVERSITY, Gorukle Kampusu, 16059 Bursa, Turkey

Objectives: The objective of this trial was to determine the effect of dietary starch concentration on locomotion and body condition scores and performance of early lactation dairy cows fed diets of different starch concentrations.

Materials and Methods: This study was performed at the Research and Application Farm of the Faculty of Veterinary Medicine at Uludag University from September 2012 to May 2013. The Animal Experimentation Ethics Committee of Uludag University approved all the experimental procedures. Twenty-four primiparous Holstein cows were randomly assigned to 1 of 3 treatments in a completely randomized design from calving through 72 d DIM. Diets contained 30% corn silage, 20% chopped alfalfa hay, and 50% concentrate/mineral/vitamin/additive mixtures (on DM basis). The concentrate mixtures were formulated by partially replacing dry ground shelled corn with wheat bran. Cows were fed the low (LS), medium (MS) and high-starch (HS) diets as total mixed ration. The dietary starch contents were 16.2, 19.8, and 24.1% for low LS, MS, and HS, respectively (DM basis). Body condition score (BCS), body weight (BW) and locomotion scores were measured weekly throughout the trial. Dry matter intake and milk yield were recorded daily

on individual cows milked 3x. Data were analyzed according mixed models procedure.

Results: There was a tendency ($P = 0.07$) for locomotion scores to be greater for MS compared to LS. Milk yield averaged 29.4 kg/d and was unaffected ($P > 0.10$) by treatment. Values for milk urea nitrogen ranged from 12.4 to 13.0 mg/dL across the treatments and was lower for cows fed MS than for cows fed the LS. The BW, BCS, and milk fat and protein percentage measurements were unaffected ($P > 0.10$) by treatment. Dry matter intake for cows fed the LS diet was 1.1 and 2.3 kg/d greater than for cows fed the MS ($P < 0.05$) and HS ($P < 0.01$) diets, respectively.

Conclusions: It was concluded that when partially replacing corn grain with wheat bran to formulate reduced-starch diets, increased dry matter intake for dairy cows fed LS may reduce feed efficiency (kg of milk/kg of dry matter intake).

Refusal to Drink in Calves in German Farms - Phenolic compounds a problem?

Martin Höltershinken¹*

¹University of Veterinary Medicine Hannover Foundation, Clinic for Cattle, Hannover, Germany

Objectives: Since four years, veterinary practices throughout Germany reported problems in cattle populations of various production systems: Calves which had been drinking their colostrum normally on their first day of life quit drinking entirely within the following two days. Their vitality declined and finally they were recumbent. Even intensive clinical care including intravenous rehydration therapy was unsuccessful. Almost all affected calves died. Scientists of the Clinic for Cattle suspected intoxication with phenolic compounds from grasses (so-called secondary plant substances) in all cases.

Materials and Methods: Thus, blood samples were taken on the second day of life and analyzed for phenols, total protein and gamma-GT. Quantitative photometric analysis of free phenols in serum of these calves was performed. The free phenolic compounds were detected by using a sum reaction with Folin-Ciocalteu's reagent (method according to Holloway et al. 1979; modified by Flaschoff 1983) with the variation coefficient being less than five percent for this method. The currently used reference values of 0.26 to 0.42 mmol/l were provided by Höltling (1993).

Results: The determination of total protein in serum showed a good ingestion and absorption of colostrum: > 50 g/l total protein in the serum. In addition, gamma-GT levels in the blood of newborn calves were higher than 250 U/l indicate adequate colostrum quality. The scientists' suspicions were confirmed and increased phenol levels could be shown in affected calves (0.6 - 1.2 mmol/l). By early separating calves from dams - after having ingested sufficient amounts of colostrum - no later than two days after birth and by feeding milk replacer or milk from cows late in lactation, the disease progress could be stopped in all affected farms.

Conclusions: Phenols are compounds with one or several hydroxyl groups attached to a benzene ring. They occur in animals partly through breakdown of aromatic amino acids by intestinal bacteria. However, considerable amounts of phenol-containing compounds are also synthesized in plants. Their functions in a plant range from being pigments to acting as defence substances. Due to the abundance of different

molecules in this substance group, a more precise characterization of the molecules responsible for the refusal to drink in calves is currently not possible.

Study of Liver Cobalt levels in Cattle and Sheep in Ireland

Seamus Fagan¹, John Fagan¹, Denise Murphy¹, Mícheál Casey², Tim Keady³, James Hanrahan³

¹Department of Agriculture, Fisheries and the Marine, Regional Veterinary Laboratories, Athlone, ²Department of Agriculture, Fisheries and the Marine, Regional Veterinary Laboratories, Backweston, ³Department of Agriculture, Fisheries and the Marine, Teagasc, Athenry, Ireland

Objectives: Cobalt deficiency has been shown to be a limiting factor in the performance of cattle and sheep production (Robertson 1971). A devastating syndrome in ruminants, now recognized in many parts of the world, was demonstrated in 1934 to be the result of cobalt deficiency, first in pastures of certain areas, then in harvested forages, and later in selected mixed rations. (Smith 1957). This study carries out analysis of cobalt levels in livers of cattle and sheep in Ireland with the aim to determine the required levels of cobalt in liver samples below which cobalt will not have a negative effect on the performance of cattle and sheep.

Materials and Methods: Recently weaned lambs (n=67) were allocated to one of the following 3 supplementation treatments: no supplement (control), Co (Cobalt) or Co, vitamin B12 plus Se (VitMin). The Cobalt treatment contained cobalt sulphate (2.1 mg/ml) only. The VitMin treatment contained B12 (200 µg/ml), cobalt acetate (10 mg/ml) and selenium selenite (0.25 mg/ml). Lambs on the Cobalt and VitMin treatments received 10 ml and 2.1 ml of drench, orally fortnightly until 18 November. Lambs were managed in a rotational grazing system on predominantly perennial ryegrass swards without concentrate supplementation. Lambs were slaughtered on either 6 November or 18 December. The day prior to slaughter a blood sample was removed from the jugular vein for determination of protein, urea, beta-hydroxybutyrate (BHB), Selenium (Se), Copper (Cu) and Glutathione peroxidase (GSHPX) concentrations. Following slaughter tissue was removed from the liver and the kidney cortex for determination of cobalt and selenium concentrations, respectively. The data were analysed as a randomised study using Proc MIXED of SAS.

Liver samples taken from cattle (n=70) and sheep (n=54) received for post mortem at Athlone Regional Veterinary Laboratory from 1st July 2015 to 30 Nov 2015 and the cobalt levels determined.

Results: The daily liveweight gain of the lambs supplemented with cobalt was 80% higher than those not supplemented from the 7th August until slaughter and 105% higher for lambs supplemented with B12+Co+Se. Relative to lambs supplemented with Co, those supplemented with B12+Co+Se had higher blood concentrations of selenium and GSHPX and higher liver Co concentration. The lambs slaughtered on the 6 Nov and 18 Dec received their last treatment drench 14 and 30 days prior to slaughter, respectively. Delaying slaughter date, and thus increasing the time interval from the last treatment drench, increased protein concentration and reduced BHB and urea concentrations in the blood, and reduced Co in the liver. Blood protein and the concentrations of Cu in blood and liver increased with delayed kill date. There was a

significant treatment x kill date interaction for Co concentration in liver. For the control, Cobalt and VitMin treatments liver Co concentrations were 0.11, 1.02 and 1.36 µmol/kg, and 0.23, 0.44 and 0.62 µmol/kg for kill date 5 Nov and 18 Dec, respectively.

In the study of cobalt levels in the livers of cattle and sheep received by Athlone Regional Veterinary Laboratory about 50% of liver samples from cattle are below 0.06ppm cobalt at which level cobalt is a limiting factor on performance (Marston 1949). 40% of liver samples from sheep are below 0.06ppm.

Conclusions: Supplementation with Co, alone or in combination with vitamin B12 and Se, increased liver Co concentration. The concentration of Co in liver declined by 55% following a 30-day period without supplementation.

The lower levels of liver cobalt in cattle versus sheep at Athlone Regional Veterinary Laboratory may reflect that sheep farmers are more likely to supplement with cobalt.

More work needs to be undertaken in Cattle on the effects of low liver cobalt/B12 on thrive in cattle in Ireland on pasture based systems.

LIPOPEROXIDATION HEPATIC IN CATTLE FEEDLOT FED WITH BRACHIARIA SP HAY AND SUPPLEMENTED WITH ANTIOXIDANTS

Roberta D. Silva¹, Gustavo L. Costa², Helton F. Oliveira³, Weygauer C. Fernandes³, Ulysses R. Correia Pinto⁴, Paulo Henrique J. Cunha³, Maria Clorinda S. Fioravanti³

¹Veterinary Medicine, Faculdades Objetivo, ²Veterinary Medicine, Veterinary School, Federal University of Goiás, ³Veterinary School, Federal University of Goiás, Goiânia, ⁴Science and Technology of Goiás, Federal Institute of Education, Ceres, Brazil

Objectives: Sporidesmin is an easily oxidized toxin produced by *Pithomyces chartarum*, a fungus that colonizes *Brachiaria* spp, and has been associated to cause liver injury in ruminants. The present study was designed to clarify, through malondialdehyde (MDA) determination in liver tissues, if administration of antioxidant supplementation reduces hepatic lipid peroxidation in bovines.

Materials and Methods: The study was conducted at the Veterinary School's farm named Tomé Pinto of the Federal University of Goiás, in São Francisco de Goiás, GO. A total of 40 Nelore bulls, aged between 24 and 36 months, were sorted into five treatments: G1 (non-supplemented control), G2 (10 mg of selenium and 1000 IU of vitamin E), G3 (600 mg zinc / animal - / day), G4 (10 mg selenium / animal / day) and G5 (1000 IU vitamin E / animal / day). The animals were fed twice a day and had water ad libitum. The diet followed the roughage and concentrate ratio 70:30. Animals were evaluated for 105 days and blood samples harvested on days 0, 56 and 105 for measurement of gamma glutamyl

transferase (GGT) and aspartate aminotransferase (AST) serum activity. Liver fragments were obtained through biopsies (0 and 56 days of confinement) and by harvesting liver tissue during the slaughter of animals at the end of 105 days of confinement.

Results: The animals showed no statistical difference for GGT and AST during the experiment ($p > 0.05$). No hepatocyte lipid peroxidation was detected by measuring MDA. Histological evaluation showed reduction in the quantitative changes in the liver parenchyma throughout the experiment. The following means were found for the parameters analyzed: TBARS (MDA mmol/Kg - G1: 9,09; G2: 6,88; G3: 7,96; G4: 7,17 and G5: 7,93); GGT (U/l) - G1: 20,24; G2: 20,61; G3: 20,45; G4: 21,41 and G5: 21,20) and AST (U/l - G1: 70,68; G2: 74,33; G3: 76,36; G4: 66,32 and G5: 76,75).

Conclusions: Among the antioxidants used as a supplement, the association of selenium with vitamin E showed the best results, minimized the occurrence of hepatic oxidative damage. Reduction was observed in the number of foamy macrophages in the hepatic parenchyma.

Milk fatty acid profile with especial emphasis on Conjugated Linoleic Acid in bulk tank milk from Chilean farms with high and low levels of grazing

Pedro Melendez¹; Pablo Pinedo²; Pablo Aranda³; Maria Paz Marin⁴

¹University of Missouri, Columbia, MO, ²Colorado State University, Fort Collins, CO, United States, ³University Santo Tomas, Vina del Mar, Chile, ⁴University Santo Tomas, Vina del Mar, United States

Objectives: Conjugated linoleic acid (CLA) is a fatty acid (FA) of milk that is beneficial to human health. As a result, there would be benefits for human population if CLA content of milk is increased. There are several factors associated with levels of CLA in milk. Cows exposed to an intensive grazing of lush pastures, especially during winter-spring season, have been shown to produce a milk richer in CLA. Consequently, the objective of this study was to compare the profile of fatty acids in bulk tank milk between two dairy farms with high concentrate/ low pasture and low concentrate/high pasture based feeding

Materials and Methods: The study was conducted in two dairy farms from the south of Chile; one dairy was classified as high concentrate (6-8 kg/cow/day), low pasture based feeding (Dairy A) and the other dairy was characterized by low concentrate (1-2 kg/cow/day), high pasture based feeding (Dairy B). Dairy A consisted of 1,000 lactating cows with a herd average of 7,500 kg ME 305. Dairy B consisted of 700 lactating cows with a herd average of 4,000 kg ME 305. Both dairies had 70% of calvings in spring and 30% of calvings in fall. During October of 2012, 3 weekly bulk tank samples were obtained from both dairies. The milk samples were obtained during the morning milking in a plastic tube with preservative and submitted immediately after collection to the laboratory for fat content and FA profile analysis. The determination of milk fat (g/kg) was determined using infrared spectroscopy. Fatty acids were analyzed by Gas Chromatograph-Mass Spectrometry of butyl esters. Results were expressed as percentage relative to each FA detected in the chromatogram according to its retention time and identification based on pure standard. Differences in milk fat (g/kg) and FA (g/kg) content between the 2 groups were analyzed by ANOVA, developing a mixed model that also included average parity number, average days in milk and farm (A, B). Least squared means were estimated and tested for significant differences. Statistical analysis was performed using the

MIXED procedure of SAS (SAS Institute Inc., Cary, NC).

Results: Milk fat content was 3.45% and 3.78% for dairy A and B, respectively ($P < 0.05$). For fatty acid profile, average (\pm SE) conjugated linoleic acid were 1.25 ± 0.01 g and 2.06 ± 0.18 g for dairy A and B, respectively ($P < 0.01$). Omega-6/Omega-3 ratio was 6.38 and 3.1 for dairy A and B, respectively ($P < 0.01$). Total saturated fatty acids were 67.2% and 66.7% for dairy A and B, respectively ($P > 0.05$). Oleic acid levels were 21.3 ± 0.92 g and 16.05 ± 0.34 g for dairy A and B, respectively ($P < 0.05$).

Conclusions: It is concluded that conjugated linoleic acid and omega-3 fatty acids are higher in bulk tank milk samples from a dairy with low concentrate/high pasture based feeding system than a dairy with high concentrate/low pasture based feeding system in the south of Chile.

Multi-mycotoxin analysis in silage – a survey from Central Europe 2015

Sabine Masching¹; Thomas Ertelthaler²; Paula Kovalsky¹; Michael Sulyok³; Ursula Hofstetter¹

¹Biomin Holding GmbH, Getzersdorf, ²IMC FH Krems University of Applied Sciences, Krems, ³Department for Agrobiotechnology (IFA-Tulln), University of Natural Resources and Life Sciences (BOKU), Tulln, Austria

Objectives: Fusarium mycotoxins like deoxynivalenol (DON), zearalenone (ZEN) and fumonisins (FUM) are still among the most frequently occurring agriculturally relevant mycotoxins. The multi-mycotoxin approach allows not only the detection of these most prevalent mycotoxins in agricultural commodities. The occurrence of masked mycotoxins and fungal metabolites, which escape routine analysis posing a possible threat to the animal's health, can be targeted as well.

Materials and Methods: A total of 20 corn silage samples and 81 grass silage samples from Central Europe were analyzed with a multi-mycotoxin LC-MS/MS method at IFA-Tulln according to Vishwanath et al (2009). The analytical method was transferred to a more sensitive mass spectrometer (QTrap® 5500) and extended to cover more than 380 metabolites (Malachova et al, 2014; Streit et al, 2013). The accuracy of the method is monitored by regular participation in proficiency tests, which includes a separate testing scheme on "animal feed" (BIPEA, Gennevilliers, France).

Results: Deoxynivalenol (DON), nivalenol (NIV) and zearalenone (ZEN) were detected in all 20 corn silage samples analyzed with average concentrations of 2,930 ppb DON, 128 ppb NIV and 958 ppb ZEN.

The masked forms of DON and ZEN, DON-3-glucoside and zearalenone-sulfate, also show a high prevalence in these samples. On average, a total of 37 metabolites were found in corn silage samples. Additionally, 80% of the corn silage samples were contaminated with fumonisins (FUM) at an average of 139 ppb. The main mycotoxins detected in grass silage were NIV, ZEN and fumonisin B₁ (FB₁) with average concentrations of 42 ppb NIV, 83 ppb ZEN and 29 ppb FB₁, respectively. Also the masked forms DON-3-glucoside and zearalenone-sulfate were detected in grass silage. On average, a total of 13 metabolites were found per sample analyzed. The most common metabolites detected in all grass silage samples were brevianamid F and cyclo (L-Pro-L-Tyr).

Conclusions: The present data highlights the high prevalence of

masked mycotoxins and metabolites that are not targeted by common analytical approaches. More data on the metabolic fate, mode of action, toxicity and possible synergistic interaction of co-contaminating mycotoxins is needed, to allow a risk assessment associated with the presence of these mycotoxins and other secondary metabolites found in silage samples.

Monitoring Ketosis in dairy cattle: effect of two different therapeutic procedures on some metabolic parameters

Enrico Fiore¹·Sonia Giambelluca¹·Matteo Gianesella¹·Leonardo Armato¹·Massimo Morgante¹

¹Department of Animal Medicine, Productions and Health, University of Padua, Legnaro, Italy

Objectives: The transition period in dairy cows is defined as 3 week pre-calving to 3 week post-calving and is the most critical phase of the lactation.

Ketosis is a common metabolic disorder that can appear during the transition period.

The aim of the present study was to evaluate the effects of two different therapeutic procedures used for preventive measures and treatment of ketosis on some metabolic parameters of lactating high-yielding dairy cows during transition period.

Materials and Methods: One-hundred-twelve Holstein Friesians dairy cows were recruited in two commercial dairy farms in North-East Italy. Cows were randomly divided into 3 groups.

Group 1: 52 dairy cows was treated with Acetyl-methionine, Inositol, Cyanocobalamin, L-alanine, L-arginine, L-threonine, L-glutamic acid (2 ml/10kg BW; IV administration; Bogras®, Ceva Salute Animale S.p.A.) at 12 and 9 days before the expected date of calving. At calving day animals were treated with Acetyl-methionine, Cyanocobalamin, thioctic acid, liver extract (20 ml per cow, 5 days; IM administration; Erbacolina®, Ceva Salute Animale S.p.A.).

Group 2: 42 dairy cows was treated with Monensin (335 mg; Oral Administration; Kexxtone®, Elanco Animal Health) 20 days before the expected date of calving.

Group 3: 18 dairy cows without therapeutic treatment (control group).

For each animal blood samples were collected from jugular vein and BCS was evaluated at 6 time points of sampling (-21±5, -7±5 days pre-partum; +7±5, +25±5, +50±5, +90±5 days post-partum). Metabolic parameters were analyzed: β-Hydroxybutyrate (BHBA), Non-Esterified Fatty Acids (NEFA), Glucose (GLU), Cholesterol (CHC), Triglycerides (TGR), Aspartate Aminotransferase (AST), Alanine Aminotransferase (ALT), Gamma-Glutamyltransferase (GGT), Urea, Total Protein (TP), Albumin (Alb), Conjugated and Total Bilirubin.

Two-way ANOVA and post-hoc Bonferroni's multiple comparison test were performed to assess the statistically significant effects of the sampling time and treatments on the metabolic parameters.

Results: Two-way ANOVA showed different effects of treatments according to sampling time points.

Lower values of BHBA were recorded from 7 days pre-partum to 25 days

post-partum in both group 1 (0.44±0.18-0.73±0.36 mmol/L) and group 2 (0.43±0.16-0.64±0.19 mmol/L) than in group 3 (0.60±0.23-1.11±0.23 mmol/L).

Group 1 showed significant lower NEFA values from 7 days pre-partum to 90 days post-partum (0.48±0.22-0.60±0.26 mmol/L) than control group (0.85±0.27-0.75±0.18 mmol/L). Statistical lower NEFA value was recorded at 7 days pre-partum.

CHC was statistically higher in group 1 from 7 to 90 days post-partum (94.798±29.53-169.14±58.12 mg/dl) with respect to both group 2 (76.796±31.59-159.76±51.15 mg/dl) and control group (71.387±20.56-132.07±41.05 mg/dl).

At 7 days pre-partum and 7 days post-partum group 1 showed lower TGR levels (17.27±7.55- 2.69±6.48 mg/dl) than control group (24.61±7.96-18.38±4.61 mg/dl). Group 2 showed a decrease in TGR levels at 7 days post-partum (14.64±6.06 mg/dl).

Statistical lower Urea levels were recorded in group 1 from 7 to 50 days post-partum (24.17±12.31-26.44±13.69 mg/dl).

Conclusions: Our findings indicate that supplementation with the combination of acetylmethionine, cyanocobalamin and α-lipoic acid positively influenced liver metabolism in high-yielding dairy cows, indicating an overall improved energy status. This supplementation may be considered as a good therapeutic agent for the treatment and prevention of liver diseases.

Only limited effects on liver metabolism and BHBA can be obtained with monensin.

Comparison of ruminal and blood gas variables of cattle induced to lactic ruminal acidosis throughout sucrose or oligofructose

Rejane S. Sousa¹·Francisco L. C. Oliveira¹·Carolina A. S. C. Araujo¹·Antonio H. H. Minervino²·Raimundo A. Barreto Junior³·Juliana A. A. Santos¹·Rafael T. Sousa¹·Clara S. Mori¹·Enrico L. Ortolani¹

¹Department of Clinical Science, Faculty of Veterinary Medicine, University of Sao Paulo, Sao Paulo, ²Federal University of Western Pará - UFOPA, Santarem, ³Department of Animal Science, Federal Rural University of the Semiarid Region, Mossoro, Brazil

Objectives: Experimental induction of acute rumen lactic acidosis (ARLA) is traditionally carried out by infusing different types of sugar (mostly sucrose or oligofructose) into the rumen of cattle. Thus, we aimed to evaluate ruminal and blood gas variables after induction of ARLA by sucrose or oligofructose.

Materials and Methods: This study was approved local Animal Ethics Commission. Eight male, two years old Nelore steers were used. The animals were fitted with rumen cannula and weighted 398 kg in average. Cattle was divided in two groups of four animals according the experimental induction protocol: oligofructose group (OG) and sucrose group (SG). For induction of ARLA the OG received 17g of oligofructose per kg of body weight (BW). In this group cattle underwent an adaptation period receiving 5% of the total dose twice a day for three consecutive days before the induction. The SG received sucrose according to the formula $y = 1057 + 43,1 \times BW^{0,75}$, where y is the amount of sucrose in grams, being reduced 20% of the total dose. Ruminal and blood samples were taken at the following moments: before induction (T0), and after six

(T6h), 12 (T12h), 18 (T18h) and 24 (T24h) hours of the induction. Rumen fluid was used of pH measurement. Blood pH, carbon dioxide pressure (pCO₂), bicarbonate and basic acid deficit (ABE), were performed in the arterial blood through portable analyzer, using commercial cartridges (i-STAT, Abbott®, Abbott Park, U.S.A). Animals were treated after T24h for complete recovering. The distribution of all data was evaluated using the Kolgomorov-Smirnov test followed by repeated measures modelling with PROC-MIXED in the SAS.

Results: The animals from both groups showed ARLA (considered when ruminal pH was lower than 5.0) already in the T6h, reaching the minimum ruminal pH values 18 hours after induction. In the comparison between groups, the animals from OG had lower ($p < 0.05$) ruminal pH (OG = 3.56 x SG = 4.01) and blood bicarbonate (OG = 33.6 mmol/L x SG = 26.6 mmol/L) in T18h. It was also observed for OG lower blood pH values in T18h (OG = 7.14 x SG = 7.33) and T24h (OG = 7.14 x SG = 7.33) and lower ABE in T12h (OG = -22.5 x SG = -7.5), T18h (OG = -19.5 x SG = -6.0) and T24h (OG = 7.11 x SG = 7.39). There was no difference in pCO₂ between groups.

Conclusions: Cattle that received oligofructose for ALRA induction presented severe ruminal and metabolic acidosis. The oligofructose protocol induced to more acute and intense ruminal and metabolic acidosis than cattle that received sucrose.

Effects of hyperketonemia within the first six weeks of lactation on milk production and fertility

Julia Ruoff¹, Stefan Borhardt¹, Annika Mahrt¹, Wolfgang Heuwieser¹

¹Faculty of Veterinary Medicine, Clinic for Animal Reproduction, Berlin, Germany

Objectives: The first 2 weeks after calving have been described as the main risk period for hyperketonemia (HYK). However, it was recently shown that dairy cows continued to be at risk for HYK until at least 42 DIM. The objectives of our study were to describe the epidemiology of HYK within the first six weeks of lactation and to evaluate the effects of HYK on milk production, reproductive performance and early lactation culling risk.

Materials and Methods: A total of 662 dairy cows from 6 commercial dairy farms in Germany were enrolled between 1 and 4 DIM. Cows were tested twice weekly using an electronic handheld meter for β-hydroxybutyric acid (BHBA) and glucose for an examination period of 42 days resulting in 12 test results per cow. Hyperketonemia (HYK) was defined as a BHBA concentration ≥ 1.2mmol/l. The onset of HYK was described as early onset (first HYK event within the first 2 weeks) and late onset (first HYK event in week 3 to 6 postpartum). Prevalence and incidence of HYK were calculated for the 12 examination days. The number of HYK events and time to a negative test event in HYK positive cows were described. The effects of onset of HYK within the first six weeks of lactation on milk production (1st test day milk yield and 100 DIM milk yield), reproductive performance (time to first service and first service conception risk), and on early lactation culling risk were analyzed separately using a GENLINMIXED procedure.

Results: Cumulative incidence of HYK was 47% and 69% for primiparous and multiparous cows, respectively. Multiparous cows had a higher incidence and prevalence of HYK within the first six weeks of lactation than primiparous cows. The peak incidence was found in the

first week of lactation and decreased steadily within the first six weeks of lactation. Prevalence stayed on the same level within the first six weeks of lactation. About 20% of all cows had one event of HYK within the first six weeks of lactation. Less than 5% of all cows had 6 or more HYK events. About 70% of HYK positive cows had a negative test result from one test to another 3 to 4 days later after the initial diagnosis of HYK. Cows with early onset of ketosis had a higher 1st test day milk yield (+2.3 kg/d, $P = 0.002$) and 100 DIM milk production (+287 kg; $P < 0.001$) compared to non-ketotic cows. There was no effect of late onset of ketosis on 1st test day milk yield and 100 DIM milk production. There was no effect of HYK on time to 1st service, irrespective of onset of ketosis and no effect of HYK on first service conception risk, irrespective of onset of ketosis. Cows with late onset of HYK had a decreased culling risk (HR = 0.365; $P = 0.045$) compared to non-ketotic cows. The culling risk of cows with early onset of ketosis was comparable to non-ketotic cows (HR = 1.447; $P = 0.212$).

Conclusions: The risk period for HYK lasted at least until lactation week 6. However, a high number of HYK positive cows had a negative test result after the initial diagnosis of HYK. Cows with early onset of HYK had higher milk production compared to non-ketotic cows. HYK was not associated with negative effects on reproduction and early lactation culling risk. HYK in early lactation seems to be part of a physiological adaptational response to negative nutrient balance in transition dairy cows.

Nutrition & Metabolic Diseases

P01-001-060

The prevalence of subclinical hypocalcaemia on a high producing commercial Dutch dairy farm and the effect of oral calcium supplementation

Rene Bemers¹, Ruben Tolboom²

¹De Graafschap Dierenartsen, Vorden, ²Boehringer Ingelheim, Alkmaar, Netherlands

Objectives: In this field-case study the prevalence of clinical and subclinical hypocalcaemia was determined at a large commercial Dutch dairy farm with a high average milk yield. Furthermore the effect of supplementation of cows with oral calcium boluses after calving on the total blood calcium concentration was evaluated. This study was initiated and executed by a veterinary practice in the Netherlands.

Materials and Methods: The herd consisted of 366 Holstein Friesian lactating cows. The average milk yield was 11270 kilograms milk per 305 days. The cows are kept indoors year-round and fed a mixed ration. In the milking parlour the cows are fed concentrates. The dry cow period last on average 35 days and the cows are housed in two groups. Both groups are given silage, maize, hay, brewers grain and dry cow minerals. The close-up group, two weeks before calving, are housed in a large pen with straw bedding. No anionic salts or special concentrates are used in the dry cow ration. Within 4 hours after calving whole blood samples were collected via venepuncture of the coccygeal vein into a serum vacutainer. Total calcium (mmol/L) was measured using the Medonic Spotchem (A. Menarini diagnostics). After the collection of this first blood sample the cow was supplemented with an oral calcium bolus (Bovicalc Boehringer Ingelheim), between 12-24 hours after the first bolus the cow received a second Bovicalc bolus. Between 24-48 hours after the second Bovicalc bolus was given a consecutive blood sample was taken, following the same procedure as the sampling directly after calving. In total 58 cows were sampled, 9 cows (15.5%) with first parity (heifers) and 49 cows (84.5%) with a higher parity. Because of practical reasons only 18 cows

were sampled twice, so before and after treatment with a Bovikalc bolus. From this group 5 cows were excluded from analyses because they also received a calcium infusion.

Results: The cut-off values for subclinical hypocalcaemia was set on 1.381 (49 animals) had an average total calcium concentration of 1.92 mmol/L with a standard deviation of 0.34. The percentage of cows with a parity >1 that had normo-calcemia subclinical hypocalcaemia or clinical hypocalcaemia was respectively; 36.7%, 57.2% and 6.1%. The group of cows (13 animals, all parity >2) that were sampled twice and were treated with a Bovikalc bolus had an average total calcium concentration at first sampling of 2.03 mmol/L with a standard deviation of 0.48. After treatment the cows had a total calcium concentration of 2.21 mmol/L with a standard deviation of 0.50. There was difference, close to statistically, between the total calcium concentrations before and after treatment (p -value = 0.06).

Conclusions: This field-case study shows that on a large well managed dairy farm in the Netherlands the prevalence of hypocalcaemia is high (63.3%). A treatment protocol with Bovikalc boluses in a small group of cows around calving and 12-24 hours later increased the total calcium concentration from subclinical to normal levels. A whole herd treatment will be beneficial on this farm and further studies will be done on the effect of this strategy on disease prevalence after calving in this particular herd.

Primary bovine hepatocytes from abattoir derived liver as in-vitro model for determinants of growth hormone receptor down-regulation

Sonja Ehrhardt¹, Sandra Wilkening², Martina Hoedemaker², Marion Schmicke³

¹Laboklin, Bad Kissingen, ²University of Veterinary Medicine, Clinic for Cattle, ³University of Veterinary Medicine, Clinic for Cattle, Endocrinology, Hannover, Germany

Objectives: The somatotrophic axis uncouples during the transition period; meaning the growth hormone receptor expression (GHR) in the liver decreases. Next to insulin, other factors are known to influence the hepatic GHR-expression and -signal transduction (e.g. thyroid hormones, sexual steroid hormones, fibroblast like growth factor 21 etc.). The aim was to establish a long-term primary hepatocyte cell culture from bovine abattoir derived liver expressing the growth hormone receptor (GHR) in a sandwich culture system in order to study the effect of single endocrine, immune and metabolic factors affecting the GHR in future.

Materials and Methods: The caudate lobe of the liver was taken 20 min after slaughtering, rinsed by ice cold Eurocollins buffer (Giantin et al. 2012), and after 2h transport to the laboratory on ice, the liver was re-warmed for five minutes at room temperature. Thereafter, cannulas were inserted in four vessels at the cut surface and fixed by tissue glue. A three-step-collagenase perfusion was performed until the extracellular matrix was abrogated. After washing, viable hepatocytes were separated using Easycoll™ and viability was proven by Trypan blue staining. The cells were seeded on collagen coated plates with Williams E Medium containing 10% FCS. After 2 h adhesion, medium was replaced and the cells were either cultured (without FCS, 37°C, 5% CO₂) for 4 d in a monolayer (ML) or with a collagen overlayer as a sandwich culture (SW) for 10 d. After establishing this protocol, the procedure was repeated (8 times), and cell samples for mRNA-expression of apoptosis markers (Bax, Bcl2-xL, Fas Ligand) and for GHR1A and IGF-1 mRNA expression

were taken, as well as medium samples for urea measurement. The viability during the cell culture was proven by using the Live and Dead Cell Staining Kit (Abcam, Cambridge, UK).

Results: The mean viability was 86 ± 7 % after purification. In ML and SW, the cells changed morphologically from roundish-spherical to polygonal hepatocyte like cell shape and build cell-cell contacts. The mRNA-expression of apoptosis markers stayed low during the separation procedure and during culture ($P < 0.05$). The urea production was higher in ML than in SW culture during the first three days, and in both urea concentration in the medium decreases during the first three days. In SW culture hepatocytes stayed vital with continuous urea production until day 10. The GHR-expression (mean \pm SD, 48.4 ± 7.3) decreased after purification (30.9 ± 9.6 ; $P = 0.0155$), whereas IGF-1 expression stayed constant (2.87 ± 0.94 vs. 2.81 ± 1.10 ; $P = 0.9288$).

Conclusions: In conclusion, viable hepatocytes can be obtained from abattoir derived bovine liver and cultured for 10 days in sandwich-culture. This promising in-vitro model of bovine hepatocytes can be used to characterize single factors affecting the GHR-expression in dairy cows. Next to the GHR-expression in future experiments the functionality of the receptor should be proven by addition of bovine GH.

Development of wireless sensors for the measurement of rumen milieu parameters in cows

Dana Kumprechtova¹, Roman Cecil², Petr Homolka³, Filip Jancik⁴

¹Nutrition, Institute of Animal Science, Prague, ²Department of Cybernetics, West Bohemian University, Pilsen, ³Department of Nutrition, Institute of Animal Science, ⁴Department of Nutrition, Institute of Animal Science, Prague, Czech Republic

Objectives: For further experimental purposes a wireless device for continuous measurement physico-chemical parameters the ruminal milieu was developed at the Animal Science Institute in Prague along with the Department of Cybernetics of West Bohemian University, Czech Republic. The aim of this study was to test the reliability of the device during a one month continuous measurement in situ on dry fistulated cows.

Materials and Methods: Autonomous sensors were developed for the in situ continuous measurement of ruminal milieu parameters (temperature, pH, redox potential-Eh). The probes are placed in the rumen of cows fitted with ruminal canula. The probe sinks in the liquid phase of ruminal content due to the weight it is fitted with. The parameters are measured at adjustable pre-defined intervals (2 minutes in this study). The values measured are transferred by radio signal to the receiver placed in the barn and are shown in real time on the display of computer with a special user interface. In addition the data are stored in the flash memory inside the ruminal device. With the measurement interval of 2 min, data of 6 month measurement can be stored. Temperature is measured by a chio integrated sensor with 0.25°C accuracy. pH and redox potential are measured with glass electrodes attached to sensitive amplifiers and analogue filters integrated inside the ruminal device. pH and Eh measurement accuracy is 0.002 pH and 0.27 mV, respectively. A special software has been developed along with the device enabling decimation and smoothing of the values and creating curves.

The device prototype was placed in the ventral ruminal sac of a cannulated dry cows that received the diet consisting of alfalfa haylage, maize

silage, pea silage, barley straw and meadow hay. The measurements were performed continuously for 28 days. Feed was given twice a day, at 6 a.m. and at 2 p.m.

Results: During the measurement period no significant displacements of the device in the rumen were noted.

The mean pH values were ranging within 5,8 – 6,9. There is a marked drop in pH after the morning feeding and increase at night when the cow did not ingest much feed. These results correspond with the data reported by many other researchers.

The pH drift on the pH sensor after 28 days of continuous measurement was 0.2 pH.

The mean Eh values were ranging from -210 mV to – 150 mV and the course of the diurnal curve corresponded with the data reported in the literature.

Redox potential was increased postprandially, after the morning feeding, probably due to penetration of air oxygen with ingested feed into the ruminal milieu. The subsequent drop in Eh is due to a fast consumption of oxygen by ruminal microflora.

Because this study tested the function of the device, laboratory analyses of rumen fluid were not performed, these were included in further studies.

Conclusions: The technology of measuring ruminal parameters by an indwelling device with wireless transmission and storage of data measured enables continuous monitoring of the ruminal milieu. Such data can help evaluate the effect of diet on ruminal fermentation, stability of ruminal microflora and the impact on the health status and performance of the cow.

In the current form the method is suitable for research purposes. The next aim is to miniaturize the devices to be suitable for the use under farm conditions.

The Biogenic Amine Gaba (Gamma Aminobutyric Acid) In Grass Silages. Part 1 Examination Of The Gaba Formation And Concentration

Klaus Eicken¹·Henner Scholz²Winfried Heimbeck³Claudia Parys³Manfred Coenen⁴

¹Dairy Practice, Dairy practitioner, D-26939 Ovelgönne, ²Former Head of Clinic for Cattle Diseases, School of Veterinary Medicine, Hannover, ³Evonik Nutrition & Care, Hanau, ⁴Institute of Animal Nutrition, Veterinary University, Leipzig, Germany

Objectives: In the Netherlands, Germany and Denmark, more than 90% of the locally produced forages are stored as silage (Oude Elferink, 1999). During ensiling, one of the most significant processes in grass silages is the degradation of true protein (tp) to soluble non-protein nitrogen components (NPN) by enzymatic breakdown. In fermented forages, the NPN fraction includes peptides, free amino acids (AA), amides, amines and ammonia with free AA making up the largest part (van Soest, 1994). The free AA can undergo an anaerobic decarboxylation through microbial enzymes to biogenic amines, e.g. glutamic acid to γ-aminobutyric acid (GABA).

Materials and Methods: In Lower Saxony, near the German North Sea coast, pasture for grazing cattle or winter feed is the dominant use of the grassland, and there are mainly dairy farms in this area. Since

approx. 1996 an unspecific disease with unknown origin is observed in dairy herds of our region with the following clinical signs: 1.) beginning with lameness, 2.) followed by weight loss, 3.) cachexia and sometimes 4.) sudden death. The protein quality of the grass silage in dairy cow's rations is suspected to be the reason for this unspecific disease. To get more detailed informations, we investigated 648 grass silage samples from bunker silos in dairy farms with and without problems since 1996. Comparing the silages of farms having either a high or a low incidence of ill cows in their herds, there was only one common finding: reduced concentrations of tp in crude protein (cp) and an increased amount of NPN in the grass silages (Heimbeck et al., 2002; Coenen et al, 2004; Eicken 2005a). Because free AA make up the largest part of the NPN fraction in fermented forages, we looked for more details in the chemical composition of these silages with strong proteolysis, and analyzed a considerable increase of free AA. Particularly the GABA concentrations of 248 samples showed the following **Results:** 1 - 3 g/kg DM in grass, hay, maize silage and 2.5-15 g/kg DM in grass silages (Evonik Nutrition & Care, Hanau).

Results: Normally a grass silage with little protein breakdown contains 70% tp and 30% NPN-compounds in the cp. Between 1996 and 2000 the percentage of grass silages with tp concentrations of <40-50% in cp showed a remarkable increase. The main part of anaerobic decarboxylation of glutamic acid during fermentation is done by glutamate decarboxylase (GAD) (Syragusa et al., 2007) and leads to GABA. This chemical reaction is irreversible (Cagno et al., 2010) and can only be done by microbial enzymes (Lu et al., 2009). Especially in first cut silages higher GABA concentrations were determined accompanied by a strong tp degradation (to less than 40 – 50% in cp). (GABA detection: Commission Regulation[EC] No 152/2009 of January 2009, laying down the methods of sampling and analysis for the official control of feed). High GABA concentrations in the grass silage were only found in the herds with the unspecific clinical signs. Since several years, we studied and documented the situations in similar dairy herds of our region. The GABA concentrations of the grass silages varied between 3 to 15 g/kg DM. On many farms the rations for dairy cows contain 10 kg DM grass silage/cow/day. So the resulting GABA intake ranges between 30 to 150 g/cow/day. This is well documented for the past 8 years. Based on our experiences we assume that 40-45 g GABA/cow/day will be tolerated by the cows.

Conclusions: Since approx. 1996, an unspecific disease of unknown origin is observed in dairy herds in Northern Germany with the following clinical signs: 1.) beginning with lameness 2.) followed by weight loss 3.) cachexia and sometimes 4.) sudden death. High GABA intake with grass silage is suspected to be the reason for this unspecific disease in the dairy herds. If the GABA intake of a dairy cow (especially in peak lactation) exceeds 45 g/day for several weeks, the dairy farmer can expect a severe health risk in his herd.

Feeding Management Practices During The Transition Period - Its Effect On Disease Incidence In Dairy Farms In The Riverina Region Of Nsw, Australia

Cassandra MacDonald¹Marie Bhanugopan^{2,3}Jan Lievaart^{4,*}

¹School of Animal & Veterinary Sciences, Charles Sturt University, Wagga Wagga, NSW, ²School of Animal & Veterinary Sciences, ³EH Graham Centre, ⁴Charles Sturt University, Wagga Wagga, Australia

Objectives: 1) To identify the transition management practices currently adopted by dairy farmers in the Riverina dairying region, 2) to determine serum concentrations of calcium (Ca), magnesium (Mg), Non-esterified fatty acids (NEFA) and Beta Hydroxy Butyrate (BHOB) within the postparturient period, and 3) to assess the relationships between the transition management practices, serum metabolite concentrations, and incidence of metabolic disorders such as ketosis (SCK,CK), milk fever (MF) and retained placenta (RP) and within the first 40 days in milk (DIM).

Materials and Methods: Five participatory dairy farms out of 10 farms in the Riverina dairying area were chosen for this study. Both feeding and husbandry practices during the dry period, immediately following parturition and during early lactation currently adopted in each of the farms were recorded. Blood samples were collected from a representative sample of cows from each farm at +3 (D3) and +35 (D35) post calving. The serum separated and analysed for serum Ca, Mg, BHOB, and NEFA concentrations. Occurrence of SCK, CK, MF and RFM within the first 40 DIM was also recorded.

Results: Transition management practices during the dry period varied between the farms. Three farms had a dry period length of 5 to 6 weeks while 2 farms had the traditional 8-week dry period. Farms 1 and 2 used solely ad lib cereal hay in their transition cow rations, fed for approximately 3 weeks prior to expected calving date. Farms 3, 4 and 5 used a professionally formulated pelleted transition supplement containing anionic salts and monensin, fed with ad lib cereal hay. All farms were pasture based post calving but in addition to pasture all farms on an average fed 4 to 8.5 kg/cow/day of concentrates only Farm 5 fed 3.5 kgDM/cow/day of silage in addition. Regardless of the farm there was a significant ($P < 0.05$) difference in the serum levels of Ca, Mg, BHOB, NEFA between D3 and D35, levels at D3 were lower compared to D35. While serum electrolyte levels improved, NEFA and BHOB were higher at D35 indicating a greater degree of NEB with an increase in prevalence of SCK by D35. The serum Mg level on D3 was found to be significantly higher on farms that were fed anionic salts in the dry period. Feeding of hay ad libitum during the dry period resulted in higher mean serum Ca postpartum ($P < 0.05$). Early lactation feeding practices were found to significantly affect ($P < 0.05$) serum Mg on D3. Farms 2 and 3 had significantly lower serum Mg than Farm 4 ($P < 0.05$), Farm 4 fed a high level of concentrate during early lactation compared to other farms. Over sixty percent of cows suffering from milk fever or SCK succumbed to another disease (ketosis, RFM, metritis) event within the study period.

Conclusions: The results of the study has shown that there is a high level NEB experienced by cows in the peri parturient period which could result in a high incidence subclinical and clinical metabolic disorders within the farms in the Riverina region, which has implications on both the welfare of animals and farm profitability. The results have also shown that farms adopting good transition management practices such as having a shorter dry period and supplementation closer to calving decrease the risk of developing metabolic disorders during the peak lactation period.

Estimation Of Glucose Utilization By Peripheral Tissues In Healthy And Ketotic Cows During An Intravenous Glucose Tolerance Test

Radojica Djokovic¹; Marko Cincovic²; Zoran Ilic³; Vladimir Kurcubic⁴; Natalija Fratric⁵; Milos Petrovic⁶

¹Department of Animal science, University of Kragujevac, Faculty of

Agronomy, Cacak, ²Department for Veterinary Medicine, University of Novi Sad, Faculty of Agriculture, Novi Sad, ³Department of Animal Science, University of Pristina, Faculty of Agriculture, Lesak, ⁴Department of Animal Science, University of Kragujevac, Faculty of Agriculture, Cacak, ⁵Department for Physiology, University of Belgrade, Faculty of Veterinary Medicine, Belgrade, ⁶Department of Animal Science, University of Kragujevac, Faculty of Agronomy, Cacak, Serbia

Objectives: To estimate functional state of endocrine pancreas in healthy and ketotic cows during intravenous glucose tolerance test.

To estimate blood glucose utilization by peripheral tissues in healthy and ketotic dairy cows on the basis of changes in blood concentrations of glucose, insulin and inorganic phosphorus during intravenous glucose tolerance test.

Materials and Methods: Eight healthy and seven ketotic cows in the earliest stage of lactation were chosen from a Holstein dairy herd. The test was carried out in the morning at 9 a.m. about 3 h after feeding. A solution of glucose (500 ml of 50 %) was injected intravenously over a 5-minute period into the jugular vein of each animal. Blood samples were taken from the opposite jugular vein before (0) and 10, 30, 60, and 90 minutes after injection. The concentration of insulin in the blood serum was determined by ELISA methods (Cusabio) using a Rayto reader. Glucose and inorganic phosphorus were measured by GOT method using a Radox kit and Rayto spectrophotometers. The effect of time after intravenous glucose tolerance test on glucose, insulin and inorganic phosphorus levels was analyzed by ANOVA-procedure with a post hoc LSD test. The intensity of metabolic change during intravenous glucose tolerance test was analyzed by determining the difference in the change of glucose, insulin and inorganic phosphorus concentrations (conc. at 30 min – conc. at 0 min, t_{30-t_0}) in healthy and ketotic cows using a t-test. The relationship between the change in insulin and glucose concentrations and the change in inorganic phosphorus concentration was assessed by the simple linear regression model. The statistics software Statgraphic Centurion (Statpoint Technologies Inc. Warrenton, Va, Virginia, USA) was used.

Results: After intravenous infusion of glucose solution, blood glucose and insulin values in both groups of cows increased significantly within 10 and 30 minutes of the experiment ($p < 0.05$). In ketotic cows, mean blood insulin and glucose levels were significantly lower than in healthy cows during 10, 30 and 60 minutes of the experiment ($p < 0.05$). After intravenous infusion of glucose, inorganic phosphorus levels decreased in blood ($p < 0.05$) in both groups of cows. Statistically significant lower ($p < 0.05$) values in blood inorganic phosphorus were determined in ketotic cows than in healthy cows during the test period. The increase in insulin and glucose concentrations and the decrease in inorganic phosphorus concentration (30 minutes - 0 minute) were statistically higher ($p < 0.05$) in healthy cows compared with ketotic cows. A strong correlation was established between blood glucose, insulin and inorganic phosphorus levels in both groups of cows, with significantly ($p < 0.01$) higher changes in the blood parameters found in healthy cows than in ketotic cows.

Conclusions: Low insulin secretory responses in ketotic cows are likely due to the low pancreatic capacity for insulin secretion that develops during the days or weeks of malnutrition-induced hypoglycemia which is generally accompanied by ketosis. The statistical analysis revealed a strong correlation between blood glucose, insulin and inorganic phosphorus levels in both groups of cows, with significantly higher changes in the tested blood parameters in healthy cows than in ketotic cows. The results suggest a higher degree of blood glucose utilization by peripheral tissues in healthy cows during the intravenous glucose tolerance test.

Effect Of The Supply Of Viusid Vet On The Productive Behavior Of Mestizos Holstein X Cebú Calves Of Different Ages

Ibrahim C. Herrera¹, Juan Carlos R. Fernández¹, Vicente M. García¹, María L. Plasencia¹

¹Medicina Veterinaria, Universidad de Sancti Spiritus, Sancti Spiritus, Cuba

Objectives: You can not aspire to an efficient and productive livestock to not achieving adequate development of calves in the early stages of life, which is closely related to his subsequent behavior. The objective of this essay was evaluate the influence of the supply of VIUSID vet used as a food additive on the bio productive behavior of Holstein calves and mestizos Holstein x Cebu calves of different ages in an artificial breeding system in Cuba

Materials and Methods: The study was carried out in the artificial breeding center of the "Dos Rios" Genetic UEB, of the province of Sancti Spiritus, Cuba. For this, four experiments were carried out on a total of 234 animals.

VIUSID vet contains: Malic acid, Glucosamine, Arginine, Glycine, Ascorbic Acid, Folic Acid, Monoammonium Glycyrhizinate (extracted of the root of Glycyrhiza glabra), Pyridoxine Hydrochloride, Cyanocobalamin, Calcium Pantothenate and Zinc Sulfate. The product undergoes a biocatalytic process of molecular activation to improve their biological activity and the biochemical reactivity of all their molecules.

In experiments 1 and 2, 59 and 60 calves were used respectively, which were younger than 2 months, and in experiments 3 and 4, 60 and 55 calves were used respectively, with ages between 4 and 5 months. All experiments were performed in different ships. In all the trials, the animals were divided in 3 homogeneous groups taking into account age, body condition and breed. The treatment applied was as follows: group I was used as control group, groups II and III received 2 g and 4 g of VIUSID vet, along with milk or concentrated, depending on age for 35 days. The variables studied were: initial weight (baseline), final weight (35 days trial), weight gain, average daily gain, hematocrit, hemoglobin, incidence of diarrhea, mortality and its causes, incidence of other diseases

Results: It was observed that the average increase of weight per calf, in the first experiment was significantly higher ($p < 0.05$) than 5.9 kg and 8.3 kg in groups II and III respectively, in regards to the control group; in experiment 2, the average weight increase was higher in 7.8 kg and 15.6 kg in the groups II and III respectively in regards to the control group; in the third experiment, the calves gained 7.5 kg and 10.5 kg more, in the groups II and III respectively in regards to the control group, and in the experiment 4, the average weight increase per animal was higher in 6.6 kg and 5.3 kg in groups II and III respectively in regards to the control group. No significant differences were found in any of the experiments in the results of the hematological studies or in the incidence of disease and deaths between the studied groups.

The better behavior of the animals can be given by the effect of product composition, which may be supplementing important elements necessary for the growth and development functions of these animals, especially if one considers that the molecular activation is performed at the same effects that it incorporates no components by themselves

Although no significant differences between the animals under study, in the treated groups there was a slight increase in hematocrit and hemoglobin at the end of the experiment, which allowed the group III

minimum values reach normal hematocrit, not the case in the Control group, this value Decreased, sharpening anemia presenting more animals

Conclusions: In experiments where animals younger than 2 months of age were used, there were significant differences between the treated groups compared to the control, but not between the two treated groups

In experiments where animals are aged between 4 and 5 months, the group receiving 4 grams of Viusid, It behaved significantly better than receiving 2 grams and both groups performed better than control

No significant differences were found in terms of hematological parameters between groups

Ruminal phenolic content and impact of soybean meal by feeding grass silages containing different levels of true protein in vitro

Norbert Göres¹, Katharina Glöckl¹, Corinne Hunsche¹, Marina Ille¹, Christopher Schulte¹, Anna Thomsen¹, Martina Hoedemaker¹, Martin Höltershinken¹

¹Clinic for Cattle, University of Veterinary Medicine Hannover, 30173 Hannover, Germany

Objectives: Grass silages containing < 50 % true protein (TP) in total crude protein (CP) are suspected to cause a clinical picture in dairy herds called 'Faktorenerkrankung Milchviehherde'. In practice soybean meal improved the symptomatology. Previous studies in vitro have shown an increase of phenolic compounds in bovine ruminal fluid when suspected grass silages (TP/CP < 50 %) were fed. An in vitro study was conducted to assess the effect of soybean protein on the ruminal content of total phenolics and o-diphenols during fermentation of grass silages with TP/CP < 50 %.

Materials and Methods: In the experiment 2 x 4 runs with duration of 28 days a time were conducted using the RUMen Simulation TECHnique (RUSITEC). Two different grass silage pairs were tested in 4 RUSITEC runs each (R1-4 and R5-8). During the adaptation and control period (9 days) grass silages with TP/CP > 50 % (CS) and corn starch were fermented in all three fermenter groups (control, I, II). In the following experimental period (10 days) fermenter groups I and II were fed grass silages containing TP/CP < 50 % (TS) and group II with addition of soy protein. During the end period (9 days) the initial diet was added to all fermenters again. The two grass silages compared in each trial were harvested from the same fields. In daily taken samples of ruminal fluid the total phenolic content was measured using the semiquantitative colorimetric Folin-Ciocalteu method. The content of o-diphenols was quantified with a semiquantitative colorimetric method after performing an alcoholic extraction.

Results: The contents of total phenolics and o-diphenols stabilized in all eight trials during the adaptation and control period. A change of grass silages fed by day 9 resulted in a significant shift of detected phenolic quantities. The effects of TS addition were most visible on days 15 to 19. At that time the total phenolic content was lowered by addition of TS in R1-4 (group I: -20,7 %; group II: -19,7 %; $p < 0,001$) and increased in R5-8 (group I: +12,8 %; group II: +12,1 %; $p < 0,001$), respectively. Simultaneously o-diphenol levels declined in R1-4 (group I: -5,11 %; group II: -6,24 %; $p < 0,001$) and at a lower extend in R5-8 (group I: -1,89 %; $p < 0,001$; group II: -2,31 %; $p < 0,01$). The soy protein

supplementation had no noticeable effect. After switching back to the control ration on day 19, the concentrations of phenolic compounds aligned with the control again within four days. The control values were consistent during the whole trial.

Conclusions: It could be shown that grass silages with TP/CP < 50 % had significant effects on the phenolic composition of the ruminal fluid. The mechanism of the beneficial effect of soybean meal seen in practice could not be elucidated in this study. Although there was no explicit monodirectional change in the total phenolic content identifiable, it appears likely that the phenolic composition of a diet can influence the ruminal digestion.

P01-001-068

The effect of autolysed yeast supplementation on in vitro rumen fermentation in high versus low fiber rations

Annamaria Boczonadi ¹*Christian Stoiber²Jutta Kesselring ¹Ilse Dohnal²

¹BIOMIN Holding GmbH, Getzersdorf, ²BIOMIN Research Center, Tulln, Austria

Objectives: Autolysed yeast is the result of a standardized degradation of the yeast cell by its own enzymes, providing immediately available functional components, which have a prebiotic effect on rumen microbiota.

The objective of this study was to test the effects of an autolysed yeast, Levabon® Rumen E, in high-fiber ration (HFR) and low-fiber ration (LFR) in two independent in vitro rumen simulation trials.

Materials and Methods: The in vitro trials were carried out using the rumen simulation system (RSS), at the BIOMIN Research Center (Tulln, Austria). The RSS allows continuous fermentation in 12 individual reactors for 15 days at 39 °C, under constant stirring and inflow of synthetic saliva. In two consecutive experiments the reactors (total volume of 1.5 l) were inoculated with rumen fluid and solid digesta from slaughtered animals and fed daily with 20 g of total mixed ration. Forage to concentrate ratio in LFR was 30:70 and in HFR 55:45 on dry matter basis.

In each of the two rumen fermentation trials six reactors received LFR and the other six HFR. Three reactors per diet received autolyzed yeast (*Saccharomyces cerevisiae*, Levabon® Rumen E) on top of their ration at a level equivalent to 30 g/animal/day. Fresh feed was provided once a day and remained in the reactors for 48 hours. After a one-week adaptation period rumen fluid was sampled for analysis of volatile fatty acids (VFAs) and bacterial abundance via cannula from each reactor. VFAs were analyzed by high performance liquid chromatography (HPLC); bacterial counts were determined using flow cytometry.

For statistical evaluation general linear models were calculated in SPSS version 19 with trial number as co-variable. The level of significance was p<0.05.

Results: Concentrations of acetate and propionate were higher in the LFR compared to HFR for both, control and Levabon® Rumen E groups. Although Levabon® Rumen E supplementation in the LFR increased acetate and propionate production in both trials; this was only significant for acetate at 360 hours of fermentation. The acetate-propionate ratio

was significantly higher in reactors receiving HFR compared to LFR diet in both groups. Higher bacterial counts were observed in the Levabon® Rumen E supplemented group in both LFR and HFR ration. Levabon® Rumen E supplementation increased on average acetate production by 12%, propionate by 13% and bacterial counts by 35% on LFR and also increased acetate by 1%, propionate by 6% and bacterial counts by 13% on HFR.

Conclusions: A significant increase of the acetate-propionate ratio in HFR compared to LFR was observed in vitro. This corresponds well to results of a meta-analysis of in vivo data, stating that cellulose supplementation increases the acetate-propionate ratio, while starch and soluble carbohydrates typically lead to a lower ratio (Murphy et al, 1982).

Levabon® Rumen E supplementation stimulated VFA production and bacterial counts in both rations; however, it had a particularly strong effect in LFR. This positive influence was observed reproducibly in two independent in vitro trials, using rumen fluid from different animals as inoculum.

Dietary Supplementation With Organic Chromium Mitigates Weaning Stress In Beef Calves

Isadora K. F. SOUSA ¹Rejane S. SOUSA ¹Clara S. MORI ¹Kedson A. L. NEVES ²Adriana C. MORINI ²Antonio H. MINERVINO ²Enrico Lippi Ortolani ¹*

¹Department of Clinical Science, Faculty of Veterinary Medicine, University of Sao Paulo, São Paulo, ²Federal University of Western Pará - UFOPA, Santarém, Brazil

Objectives: Weaning is one of the most stressful episodes in the lifetime of a calf and the lactating cow. There are several changes in the management of weaning to decrease the outcome stress. Most of them depends on the handlers and the farmer pawns no so easy to manage. Thus, other factor independent of these personals are required. One possibility is the use of organic chromium that in stressful situations brings beneficial results to the animals. The objective of this experiment is to evaluate the use of organic chromium to mitigate the stress of weaning.

Materials and Methods: An Official Brazilian Animal Ethics Commission approved this protocol, previously.

One hundred and fifty crossbred six-month beef male (74) and female (76) Nellore and Nellore crossbred calves were used. These calves were distributed into two equal groups and both received a corn, soybean meal, mineral supplement on a 0.1% BW daily basis, in a creep feeding, throughout the 60 d before and 60 d after the weaning. It was included in the diet of one group 0.9 mg Cr/100 kg BW of organic chromium. Body weight was measured and samples were collected at different times (day 0, weaning, 48 h after weaning (48W) and at the end of the experiment) to measure serum cortisol, glucose, total protein and albumin, chromium, and urinary chromium and creatinine. At 48 W the temperament of the calves was assessed by the scale composite score to classify them as

calm or stressed calves. The distribution of all data was evaluated using the Shapiro-Wilk test followed by repeated measures modelling with PROC-MIXED in the SAS. The Qui-square test was also performed.

Results: The chromium supplementation increased significantly the weight gain before weaning, with an (average of 5.6 kg), and throughout the experiment (6.5 kg); decreased the number of stressed calves (24/75 and 6/75), and the serum levels of cortisol (76.5 x 63.7 nM cortisol) ($P < 0.01$). The weaning stress caused an increased urinary excretion of chromium (498.5 x 336.7 nM Cr), independent of Cr supplementation, and the urinary index of excretion of chromium (24.5 x 9.5 nM Cr) being highest in the stressed calves with high levels of cortisol ($P = 0.04$).

The results showed that weaning stress could deplete the reserves of body chromium by increasing its urinary excretion, but the dietary supplementation of Cr by creep feeding can overcome this depletion resulting in a lower production of cortisol and a less stressful weaning, since Cr modulates the production of cortisol.

Conclusions: The detrimental effects of weaning triggered in the most stressed calves higher levels of serum cortisol, greater excretion of urinary chromium and decreased their weight gain throughout this time, but this condition can be mitigate and corrected in most calves by dietary supplementation of organic Cr.

Influence of GLP-1 and GLP-2 on the epithelial barrier of the ovine rumen

Gabriele Greco¹; Carolin Deiner¹; Salah Amasheh¹; Joerg R. Aschenbach¹

¹Veterinary-Physiology, Free University of Berlin, Berlin, Germany

Objectives: The epithelial barrier of the ruminal epithelium is provided by a tight junction protein (TJ) strand network sealing the space between contiguous cells. It constitutes the intercellular fence against solutes, microorganisms and toxins. In jejunal epithelia of monogastric organisms, it has been shown that the epithelial barrier can be tightened by glucagon-like peptide 2 (GLP-2) (1). On the other hand, glucagon-like peptide 1 (GLP-1) decreases endothelial permeability in injured mesenteric endothelium (2). Against this background, we addressed the hypothesis that GLP-1 and GLP-2 may also affect the epithelial barrier of the ovine rumen.

Materials and Methods: Six adult sheep were fed on standardized 80% hay and 20% concentrate diet for at least 2 weeks prior to the experiment. Sheep were stunned and exsanguinated, and ruminal tissue was removed from the ventral ruminal sac. The epithelial layer was stripped off the *tunica muscularis* and *tunica serosa*. Epithelia were cut in ~3x3 cm pieces and mounted in Ussing chambers with an exposed area of 3.14 cm². The incubation buffer on the mucosal side was titrated to pH 6.1 and contained short chain fatty acids (SCFA; 40 mM). The incubation buffer at the serosal side had a pH 7.4 and was SCFA-free. Epithelial conductance was continuously monitored under short-circuit conditions. One control group was incubated for 7 hours in buffer solution without hormones. Simultaneously, four treatment groups were incubated on the serosal side with incubation buffer containing either 25 nM or 250 nM of either GLP-1 or GLP-2. After 7 hours, epithelial samples were collected and stored in RNA later. The changes in mRNA expression of the TJ proteins claudin-1, -4, -7 and occludin were measured by reverse transcription quantitative real-time

PCR (RT-qPCR). Statistical analysis was performed with the software SPSS 22 using one-way ANOVA and the post-hoc Dunnett test.

Results: The electrical conductance was not different between control epithelia incubated without hormones and epithelia incubated with GLP-1 or GLP-2 at the two tested concentrations. However, the mRNA patterns of tight junction proteins were different between epithelia incubated with and without hormones. The mRNA expression of claudin-7 decreased in all epithelia incubated with GLP-1 at 25 nM (by $-75 \pm 7\%$) or 250 nM (by $-82 \pm 8\%$), as well as GLP-2 at 25 nM (by $-56 \pm 10\%$) or 250 nM (by $-57 \pm 9\%$), when compared to control expression (all $P < 0.05$). The mRNA expression of occludin increased only in epithelia incubated with 250 nM of GLP-2 (by $+239 \pm 75\%$; $P < 0.05$) but was not different to controls in the presence of 25 nM or 250 nM GLP-1 or 25 nM GLP-2. The mRNA expression of claudin-1 and claudin-4 was not different between epithelia incubated with or without hormones.

Conclusions: We conclude that both GLP-1 and GLP-2 decrease the mRNA expression of the tight junction protein claudin-7. Very high concentrations of GLP-2 additionally increase the mRNA expression of occludin. These changes may be relevant for adaptation processes of the ruminal epithelium in the longer term but may not be associated with immediate changes in epithelial barrier function.

Comments: This study was supported by an Elsa Neumann stipend of the state of Berlin to G. Greco.

Changes in Several Serum Microminerals (Cu, Zn, Mn And Se) Concentrations associated to Management System in Dairy Cows in Galicia

Joaquín Hernández¹; Angel Abuelo²; Jose Luis Benedito¹; Victor Pereira¹; Jose Miguel Chapel¹; Cristina Castillo¹

¹Animal Pathology, Universidade de Santiago de Compostela, 27002 Lugo, Spain, ²Graham Centre for Agriculture Innovation, NSW Department of Primary Industries, Charles Sturt University, Wagga Wagga, Australia

Objectives: This study aimed at: i) investigating the effect of the management system (organic vs. conventional) on the serum concentrations of Cu, Zn, Mn and Se; and ii) studying the temporal changes of these minerals around the time of calving

Materials and Methods: This study was conducted in 3 herds, two organic (considered as an experimental group, where animals don't receive any kind of mineral supplementation) and one intensive farm (where animals receive a mineral supplementation in the diet), located nearby in Galicia (NW Spain). Blood samples were obtained at different time points by coccygeal venepuncture from 41 organically managed HF cattle (21 from organic herd A, 20 herd B) and 37 intensively managed cattle. Sampling took place at the dry-off (60-30 days before expected calving), close-up (29-3 days before expected calving), fresh (3 to 30 DIM) and peak lactation (31 to 60 DIM) stages, as well as during mid-lactation (180-210 DIM). Serum concentration of Cu, Zn, Fe and Se were determined by inductively coupled plasma optical emission spectrometry (ICP-OES). Data were analysed statistically through the GLM procedure

of SPSS v20.0, including the fixed effects of management regimen, productive stage and their interaction. Post-hoc analysis was conducted with the Bonferroni test.

Results: The majority of the serum parameters, except Se, were with physiological ranges. Considering the management system, the lower concentration of Se was lower in the organic herds, whereas the concentration of Mn and Zn was higher in the organically managed cattle. For serum Mn and serum Zn, organic herds showed higher and statistical different levels than intensive herd. Considering the productive stage, statistical differences were only observed in one of the organic herd (herd A) between the mid- and early lactation stages. Serum Zn was lower during the fresh period both in the intensive and the organic herd A, increasing its concentration during peak of lactation. Finally, with regards to the serum concentration of Cu, it was lower in the organic farms; and considering the productive stages, the highest concentrations were found during the lactation peak and the lowest during close-up in both the intensive and the organic herd A. No differences throughout the study period were found in the organic herd B.

Conclusions: The changes over time around calving of the serum concentration of Cu, Zn, Mn and Se were not different between organically and intensively managed dairy cattle. Indeed, in one of the farms (herd B), these concentrations remained stable throughout the study period. In addition, the concentration of these microminerals fell within the reference intervals in both management types.

Effect Of Particle Size Level And Forage Level On Physical Efficiency Of Total Mixed Rations Of Dairy Cows

Pedro A. Robles-Trillo¹ Rafael Rodríguez-Martínez² Pedro Cano Ríos¹ Francisco G. Veliz Deras³ Isis Moraga³ Alfonso Nava³

¹Producción Animal, ²Ciencias Médico Veterinarias, ³Universidad Autónoma Agraria Antonio Narro, Torreón, Coahuila, Mexico

Objectives: The present research was conducted in order to determine the effect of two particle sizes of forage (short, SF and long, LF) and two forage levels (high, 60% HF and low 45% LWF, of DM) upon physical efficiency of completely mixed diets (CMD) offered during 30 d to commercially managed dairy cows.

Materials and Methods: In order to determine the effect of the particle's size over the physical efficacy of the administrated ration to Holstein cow was used a hammered mill which counted with two screens to obtain shredded alfalfa with two different particle's sizes. Both forage's levels were obtained by proportioning two forage's levels on diet, one with a 60:40 ratio, meanwhile the other with a dry mass ratio of 45:55. To determine the daily particle size distribution (PSD) and the physical efficiency of the diet (ef) a particle separator from the University of Pennsylvania (PSPS) was used. To estimate the physical efficiency of the neutral detergent matter (ef NDF) of the CMD the ef was multiplied by the NDF of the ration. The data was analysed by a 4x4 latin square with a factorial adjustment of 2x2.[P1]

[P1]

Results: The particle retention from the 19 mm screen was affected ($P < 0.001$) only by the particle size of the CMD. Meanwhile, the level of inclusion of the forage had an effect ($P < 0.001$) upon the amount of particles retained on the 8 mm screen. The amount of particles distributed

on de 1.18 mm screen was affected ($P < 0.001$) by the particle size as well as by the level of forage on the ration. On the other hand, the particle size had a significant effect ($P < 0.001$) upon the rations ef₂, having a larger amount on FL rations than SF (0.494 vs 0.474, respectively). The level of forage on the ration also affected the ef₂, finding a bigger amount on rations with LWF. On the ef₃, effect ($P < 0.001$) was shown on SF rations with larger amounts than LF (0.847 vs 0.835, respectively). The ef₂ NDF was not affected either by particle size or level of alfalfa inclusion. Both forage particle size and level of alfalfa inclusion affected ($P < 0.001$) the ef₃ NDF of the CMD.

Conclusions: In conclusion, the level of inclusion and particle size of alfalfa allows that a larger amount of feed is retained on the 19 mm screen but the amount of forage on the ration allows a greater physical efficiency of the NDF of cow's rations.

In situ ruminal biohydrogenation of fatty acids of whole cottonseed affected with vitamin E or monensin

Maghsoud Besharati¹ Akbar Taghizadeh¹

¹Department of Animal Science, University of Tabriz, Tabriz, Iran, Islamic Republic Of

Objectives: The aim of this study was to compare the kinetics of ruminal disappearance of unsaturated Fatty acids of ground whole cottonseed (WCS) affected with vitamin E or monensin using in situ nylon bags methode.

Materials and Methods: Two fistulated rams with the age of 15–20 months and 37 kg live weight were housed in individual pens for in situ trial. Animals were fed a completely mixed ration on maintenance level. The sheep were fed twice a day at 08:00 am and 16:00 pm. Seven days were assigned to adapt animals to the diet. There were 3 periods including 1) Whole cotton seed without additive, 2) WCS with Vitamin E (500 IU per kg DM) and 3) WCS with Monensin (24 ppm per kg DM per day). The times of incubation were 0, 2, 4, 8 and 24 h. Fatty acid methyl esters of oilseed samples were prepared using direct fatty acid methyl ester synthesis method. For GC-MS analysis, an Agilent 6890 gas chromatography with a 30m to 0.25mm HP-5MS capillary column coupled with an Agilent 5973 mass spectrometer (Agilent Technologies, Palo Alto, CA) operating in EI mode at 70 eV was used. Proportions of individual fatty acids in bags were analysed for ground WCS, using the general linear model of SAS Institute.

Results: The results show that unsaturated Fatty acid (%) for treatments (1. WCS, 2. WCS +vitamin E and 3. WCS + monensin) at 2 h incubation were 34.26, 38.93 and 25.59 percent respectively, and treatment 2 numerically had the highest USFA content at time 2 h incubation. After 24 h ruminally incubation, treatment WCS + Vitamin E had highest USFA content among treatment (27.59%) and treatment WCS + monensin had the lowest USFA content (11.20%). The rate of Biohydrogenation for treatment 1, 2 and 3 were 9.55, 10.43 and 13.80 % per h, respectively.

Conclusions: Adding vitamin E reduced ruminally biohydrogenation of USFA and adding monensin increased ruminally biohydrogenation of USFA. Vitamin E could minimize the formation of trans-10 isomers in the rumen.

Changes in colostrum composition in dependence on the time of parturition

Josef Illek¹, Veronika Sujová¹, Jana Šmídková¹

¹University of Veterinary and Pharmaceutical Sciences Brno, Brno, Czech Republic

Objectives: The objective of our work was to determine the dynamics in the changes of concentration of selected parameters (Total protein, total immunoglobulin, immunoglobulin IgG1, lactoferrin, GGT, vitamins A and E) of bovine colostrum in dependence on the time of parturition.

Materials and Methods: Colostrum and milk samples were collected from the total yield from 10 cows of Holstein breed with the average performance of 10,850 kg of milk per standard lactation in the following periods.

The first sample was collected 1-2 hours after parturition (collection 1)
The second sample was collected 6-12 hours after parturition (collection 2)
The third sample was collected 32-48 hours after parturition (collection 3)
The fourth sample was collected 60-90 hours after parturition (collection 4)

Colostrum samples were deep-frozen and kept at the temperature of 70°C until the time of analyses.

Total protein, total immunoglobulin concentration, immunoglobulin IgG1, lactoferrin, gamma-glutamyltransferase, vitamins A and E were determined in the samples of colostrum and milk.

Vitamins were established in whole colostrum using the method of liquid chromatography, other specified endpoints were determined in the treated colostrum by repeated centrifugation in the so-called cell-free and casein-free colostrum.

Total protein was determined colorimetrically on a Cobas Mira automated analyser using the 12751 P. f. Bio Vendor kit. Immunoglobulins (Ig) were determined by electrophoresis, immunoglobulins IgG1 were determined by radial immunodiffusion, lactoferrin, vitamins A and E were determined by liquid chromatography. The results were statistically evaluated. Mean values (X) and standard deviation (SD) were determined.

Results: Composition of colostrum changes after parturition significantly. Colostrum obtained from the first yield, in our case within 1-2 hours after parturition, had the highest concentration of all monitored parameters (total protein 129.04 g/l, IgG1 16.71 g/l, lactoferrin 1438.36 mg/l, GMT 2180.2 uka/T/L, VIT. A 17.91 UMOL/L, VIT. E 17.04 umol/L. Compared with the second milk yield (6-12 hours after parturition) there was a decrease in the concentrations of most parameters except vitamins A and E which remained at approximately the same level. The largest decrease was recorded in the value of IgG1 where the initial concentration 16.71 g/l dropped to 8.84 g/l. The relatively smallest decrease in the concentration between the first and second yield occurred in lactoferrin. From the third yield, i. e. after 32-48 hours, the concentrations of the monitored parameters in colostrum decreased rapidly, namely in total protein to 36.22g/l, IgG 3.33 g/l, lactoferrin to 601.28 mg/l, vit. A to 8.25umol/l and vitamin E to 7.44 umol/l.

Conclusions: The composition of colostrum in the period after calving changes significantly. The best quality colostrum comes from the first yield obtained immediately after parturition. The first colostrum has a high concentration of protein, with the highest proportion of immunoglobulins. It also has a high content of fat, minerals and vitamins. Other biologically active components are present in colostrum in concentrations higher than in milk. The concentrations of the monitored parameters reduced significantly in time after parturition.

Comments: The paper is based on the IGA VFU Brno project

Addition Of Molasses And Corn Steep Liquor As Economical Sources To Enhance The Fungal Biomass Production Of Wheat Straw By Arachniotus Sp.

Faisal Shahzad¹, Muhammad Abdullah², Abdul S. Chudhry³

¹University College of Veterinary & Animal Sciences, The Islamia University of Bahawalpur, Bahawalpur, ²Livestock Production, University of Veterinary and Animal Sciences, Lahore, Lahore, ³School of Agriculture, Food and Rural Development, Newcastle University, Newcastle, Pakistan

Objectives: The study was planned to see the additive effect of various industrial residues including molasses (0, 0.2, 0.4, 0.6, 0.8 mL), rice polishing (0, 0.2, 0.4, 0.6, 0.8 gm) and corn steep liquor (0.5, 1.0, 1.5, 2.0, 2.5 and 3.0 mL) for bioprocessing of 5gm wheat straw (WS) through solid state fermentation (SSF) using Arachniotus sp. as fermenting agent.

Materials and Methods: Wheat straw (5g) used as solid state fermentation substrate was added into duplicate erlenmeyer flasks and adjusted at a substrate to water ratio of 1:2 on 4th day of incubation at 28°C and different salts concentration MgSO₄·7H₂O (0.050%), CaCl₂ (0.075 %), KH₂PO₄ (0.150%) and urea (0.15%) in growth medium. Inoculum (1 mL) of spore suspension (10⁶ to 10⁷ spores/mL) of Arachniotus sp. was added in the growth medium of each flask to obtain the maximum fungal protein. Crude protein contents of samples were tested according to the procedures of AOAC, 2006.

Results: A linear significant progressive increase in CP contents (p<0.001) was observed with increasing levels of C:N ratio. i.e. 0:1 (3.94%), 5:1 (3.99%), 10:1 (4.38%), 15:1 (4.65%), 20:1 (4.70%), 25:1 (4.81%) and decreased at 30:1 (4.59%) C:N ratio. Biomass CP contents (4.92%) were higher at 0.4mL level of molasses during SSF of wheat straw with Arachniotus sp., while the level decreased on further addition of molasses from 0.6mL (4.65%) to 0.8mL. Hence maximum fungal protein contents (13.40%) were found by cumulating 0.4mL molasses, 0.8gm rice polishing and 3.0mL corn steep liquor in treated wheat straw at a setting time of 48h for molasses and corn steep liquor in Solid state fermentation.

Conclusions: It was concluded that growth rate of Arachniotus sp. was greatly improved by addition of our selected amounts of carbohydrate and nitrogen sources. Hence, our current observations highly endorse the use of these economical by-products for cheap biomass production.

Alterations in energetic metabolism in dairy cows during the periparturient period

Mária Vargová¹, Gabriel Kováč¹, Vladimír Petrovič¹, Jana Konvičná¹

¹University of Veterinary Medicine and Pharmacy, Košice, Slovakia

Objectives: The aim of this study was to evaluate dynamics of selected parameters of energy profil in dairy cows of the Slovak Pied Cattle from 3 weeks ante partum (a.p.) to 9 weeks post partum (p.p.).

Significant differences were found in average values of non-esterified fatty acids (NEFA), total lipids (TL), total cholesterol (TCH) ($P < 0.001$) and β -hydroxybutyrate (BHB) ($P < 0.05$).

Materials and Methods: Monitored parameters of energy profile – glucose, NEFA, BHB, triacylglycerols (TG), TL and TCH were evaluated in blood serum of dairy cows ($n = 15$, aged 3–5 years) of Slovak Pied Cattle. Blood samples were taken 3 weeks (wk) before parturition (3 wk a.p.), 1 week before parturition (1 wk a.p.), 1 week after parturition (1 wk p.p.), 3 wk p.p., 6 wk p.p., 9 wk p.p. by direct puncture of v. jugularis. Mean production age was 2.5 lactation. Milk yield during the previous lactation was 6668.5 kg of milk. The animals were fed a total mixed ration (TMR) twice daily and had free access to drinking water. The concentrations of NEFA (Randox, UK) and TL (Spinreact, Spain) were assessed by spectrophotometric method - Specord 210 Plus (Analytik Jena, Germany). The concentrations of BHB, glucose, TCH and TG were determined using commercial diagnostic kits (Randox, UK) on automatic biochemical analyser Alizé (Lisabio, France). Statistical analyses were done with the GraphPad Prism 3.0 software.

Results: Circulating concentrations of NEFA and BHB measure the success of adaptation to NEB and prepartum rise in NEFA suggested that cows were already in NEB at this time. The highest concentration of NEFA was found 1 wk p.p. (1.69 ± 0.55 mmol/l). Significantly lower values were observed 3 wk a.p. and 6, 9 wk p.p. compared to 1 wk a.p. and 1 wk p.p. ($P < 0.001$, $P < 0.05$). Decreased concentrations of NEFA in dairy cows 9 wk p.p. indicate that NEB was gradually corrected by reducing lipomobilization. The serum BHB concentration is indicator of energy metabolism disruptions which is more sensitive than glycaemia and which fluctuates in parallel to lipomobilization. The concentrations of BHB increased from 0.40 ± 0.12 to 0.83 ± 0.89 mmol/l from 3 wk a.p. to 3 wk p.p. ($P < 0.05$) then gradually decreased. The lowest concentration of glucose was detected 1 week p.p. in the context of the sudden activity of the mammary gland and the increased lactose synthesis. Serum TL concentration increased significantly p.p. compared with a.p. ($P < 0.001$). In TCH concentrations were observed significantly lower values in the cows a.p. and in the early postparturient period than were determined p.p. ($P < 0.001$ and $P < 0.01$, respectively). The highest concentration of TG was recorded 6 wk p.p., during a.p. were observed a decline of values. Concentrations of TCH and TG were affected by the physiological status, both showed substantial increases during p.p. Probably because, during the puerperal period, there is an increase in the demands for regulatory mechanism, responsible for all the processes involved with milking.

Conclusions: In conclusion, our results demonstrate that variables of parameters of energy profile as NEFA, BHB and glucose changed throughout the time around calving, which suggests that they have a physiological role in the dairy cow's energy metabolism. It can be concluded that, cows were in adequate energy status during monitored period and these results confirm the ability for adaptation in different physiological stages of lactation.

Climate change and occurrence bovine reproductive conditions in the North West Province, South Africa.

keitiretse molefe¹Mulunda Mwanza^{1*}

¹Animal Health, North West University, Mafikeng, South Africa

Objectives: Climatic changes induce with reduced rain and less grazing pasture for animals. This results in the occurrence of several cases of bovine reproductive conditions. The aim of this study was to evaluate the nutritional and haematological parameters in different reproductive conditions recorded in the Animal Health Hospital, North West University between June 2012 and June 2015.

Materials and Methods: A total of 108 cases of reproductive conditions such as downer cow syndrome ($n=13$), dystocia ($n=14$), retained placenta ($n=13$), vaginal prolapse ($n=9$), abortion ($n=28$) and those from cow in the final trimester of pregnancy ($n=31$) were recorded and blood samples collected together with other management information obtained from the farmer as well as the animal general clinical presentation. Blood samples were screened for brucellosis and serum analysed for blood biochemistry parameters. Structured questionnaires were also issued to farmers during farm visits and at community outreaches organized by North West University Animal Health Department. Data were analysed in SAS (version 20) using the analysis of variances techniques (ANOVA).

Results: The results were expressed as means \pm SEM. Dystocia was found to have the highest frequency (26.2%) of prevalence, followed by abortion and retained placenta with equal proportions of 23.1%, then downer cow syndrome (20%). The survey showed that significant differences were only observed in cow age ($P < 0.0001$) and breed types ($P = 0.0245$). The biochemical metabolites in this study all showed significant differences ($P < 0.05$) in breed types. It was noted that 53.6% of aborting cows, downer cows (61.5%), dystocia (50%) and vaginal prolapses (77.8%) tested positive for Brucellosis.

Conclusions: Recent drought caused by climate change and leading to poor grazing pasture due to low rain fall, reproductive diseases such as brucellosis, poor nutrition, lack of supplementation and poor management are the main cause of the occurrence of reproductive conditions reported in this study.

P01-001-078

Evaluation Of The Application Of Viusid Vet On The Bio Productive Indicators Of Milking Cows.

Ibrahim Calero Herrera^{1*}Juan Carlos R. Fernández¹Vicente M. García¹Leticia S. Madrigal¹María Luz L. Plasencia¹

¹Medicina Veterinaria, Universidad de Sancti Spiritus, Sancti Spiritus, Cuba

Objectives: In Cuba as a third world country, the development of dairy cattle plays a very important role as each day increases the consumption of milk and its derivatives, It is these high demand for the population. The objective of this work is evaluate the influence of the supply of VIUSID vet on the bio productive behavior of milking Holstein cows

Materials and Methods: The work was performed in 16 and 17 dairy genetics Farm "Two Rivers" in the province of Sancti Spiritus, Cuba. Forty Holstein milk cows were used. In each unit, 20 cows were taken, which were divided in 2 homogeneous groups, considering the production of milk, feeding time, and body condition. The animals were carefully marked. The regime of feeding and management was the same for all animals.

The treatment used in each unit was as follows: group I. he was subject to the existing system of exploitation. Its composition was

10 animals and II was administered mixed with food during milking in proportion VIUSID 50 g of powder per animal vet for 30 days. The product is administered for 30 days but the study is extended for 50 days.

The variables studied were: milk production, presentation of jealousy and Incidence of endometritis and other reproductive disorders

Results: At the beginning of the experiment, but no significant differences, the mean values of milk production in the control group are slightly higher than the treated group, however, was observed that, starting when the cows had been eating the VIUSID vet for 21 days there was a significant increase in the production of milk in the treated animals (22.5%) in regards to the control group, said effect remained at 36 days (29.9%) and 49 days (26.6%) after the trial started, demonstrating the persistence of the effects of the product after its consumption is finished considering that it is only provided to the cows for 30 days. Also, 60% of the cows in the treated group had a heat cycle, while only 45% of the cows in the control group had it. On the other hand, in the control group, 10% of the cows presented endometritis, while in the treated group none of the cows were affected by this pathology.

The better behavior of the animals can be given by the effect of product composition, which may be supplementing important elements necessary for the growth and development functions of these animals, especially if one considers that the molecular activation is performed at the same effects that it incorporates no components by themselves

Conclusions: The supply of VIUSID vet in the studied dose significantly improves the bio productive behavior of the milking Holstein cows

There is a tendency to improve reproductive rates and reduce the incidence of endometritis in cows consuming the product

Nutrition & Metabolic Diseases

Selected variables of protein profile and their relation to indicators of lipid mobilization in dairy cows after calving

Gabriel Kovac¹ Csilla Tothova¹ Oskar Nagy¹

¹Clinic for Ruminants, University of Veterinary Medicine and Pharmacy, Kosice, Slovakia

Objectives: In dairy cows, the metabolic changes occurring in the period around calving may influence the incidence of peripartum diseases. The mechanism of association between metabolic changes and inflammatory diseases around calving is not entirely clear, but may be mediated through diminished immune-cell functions. The aim of this study was to determine the concentrations of the main indicators of lipomobilization and selected variables of protein profile in dairy cows after calving, including immunoglobulins and acute phase proteins, as well as to evaluate the relationships between the altered lipid metabolism and changes in protein profile.

Materials and Methods: Into the evaluation we included fifty four dairy cows of a Slovak spotted breed, low-land black spotted breed and their crossbreeds in the period from one to two weeks after parturition. The animals were housed in free-stalls, and fed twice a day diets for lactating cows. The evaluated cows were without health disorders during the observation. Blood samples were analyzed for non-esterified fatty

acids (NEFA), beta-hydroxybutyrate (BHBI), total proteins, albumin, immunoglobulin G (IgG), haptoglobin (Hp) and serum amyloid A (SAA). The concentrations of NEFA, BHB, total proteins and albumin were assessed using commercial diagnostic kits (Randox, United Kingdom). The concentrations of IgG and SAA were analysed by enzyme linked immunosorbent assay (ELISA) using commercially available diagnostic kits (Cusabio, China, Tridelta Development, Ireland, respectively). Haptoglobin was assessed using commercial colorimetric kits (Tridelta Development, Ireland) in microplates. The obtained results from evaluated cows were divided into two groups according to the measured concentrations of NEFA: Group A (n = 34) – cows with serum concentrations of NEFA below 0.35 mmol/l and Group B (n = 20) – cows with serum concentrations of NEFA above 0.35 mmol/l. Unpaired Student's test was used to evaluate the significance of differences in means between the groups of cows. Relationships between the concentrations of the evaluated variables in the monitored cows were calculated by linear regression and Pearson correlation test.

Results: In cows with higher concentrations of NEFA (Group B) we found significantly lower mean serum concentrations of total proteins, albumin and IgG than in cows with lower serum NEFA concentrations (Group A). On the other hand, cows with higher values of NEFA showed significantly higher mean concentrations of haptoglobin and serum amyloid A. Trend of significantly higher values in cows with higher NEFA concentrations was found also in the concentrations of BHB. The concentrations of NEFA significantly negatively correlated with the values of IgG (R=-0.638, P<0.001). Significant negative correlations was found also between the concentrations of NEFA and total serum proteins (R=-0.436, P<0.001), as well as between NEFA and albumin (R=-0.395, P<0.01). Between the concentrations of NEFA and haptoglobin, as well as NEFA and serum amyloid A significant positive correlations were found (R=0.588, P<0.001, and R=0.811, P<0.001, respectively).

Conclusions: This study indicates relationships between the concentrations of NEFA and variables of protein profile in cows after parturition. The study demonstrates that metabolic changes associated with energy imbalance and fat mobilization may be related to alterations in protein metabolism. These data contribute to the better understanding of the metabolic changes occurring in dairy cows after calving. However, further studies are needed to investigate in detail the association of changes in protein profile with alterations in lipid metabolism.

This work was supported by VEGA Grant No. 1/0203/15 from the Ministry of Education of the Slovak Republic.

Edible oil intoxication in natural cases of crossbred cows – a clinical study

Muthusamy Ranjithkumar¹ Subbiah Krishnakumar¹ Mani Saravanan¹ Kandasamy Kannan¹ H PushkinRaj¹ Soundar Satheshkumar¹

¹Veterinary College and Research Institute, Orathanadu - 614 625, India, Orathanadu, Thanjavur, India

Objectives: Edible oils particularly peanut, sesame and coconut oil are part of stable food of India. Peanut oil and sesame oil contains a high proportion of unsaturated fatty acids. Coconut oil contains high level of saturated fatty acids. Unsaturated fatty acids have more potent antimicrobial effects and promote greater inhibition of ruminal fermentation than saturated fatty acids. Hence the accidental consumption of excess quantity of edible oils produces clinical illness in cattle. This may be the

first report in edible oil intoxication. This research describes the clinical signs, treatment and clinical outcome in five oil intoxicated cases.

Materials and Methods: Research was carried out at Teaching Veterinary Clinical Complex(TVCC), Veterinary College and Research Institute, Orathanadu – 614 625, India during March 2014 to September 2015. Five animals were reported with history of Peanut (3 animals), Sesame (1 animal) and Coconut oil (1 animal) intoxication and admitted in large animal outpatient unit of TVCC mostly at summer. Three animals bearing number 2141/14, 5916/14 and 4721/14 consumed 4, 3 and 6 liters of peanut oil respectively. Others 469/15 consumed nine liters of sesame oil, and 3080/15 consumed three liters of coconut oil. The rumen fluid examination revealed no protozoal activity in three peanut oil intoxicated animals. Two animal's (469/15 & 3080/15) rumen fluid had oil bubbles encapsulated with protozoa. The complete blood count was carried out in automated hematology analyzer (Vet scan HM5, Abaxis). All the animals were treated with polyionic fluids like multiple electrolyte solution, ringer's lactate, 7.5% sodium bicarbonate, ruminotronics and B-vitamins. In three animals (2141/14, 5916/14 and 469/15) rumen gut transplantation was attempted. Sodium bicarbonate was administered orally @ 100-200 gms as total dose according to the clinical recovery. Antibiotics like Strepto-penicillin was administered with commercial preparations of ruminal antacids (Powder Bufzone*). Two animals (2141/14 & 5916/14) have intestinal mucosal shred in dung was treated with light kaolin. Owners were encouraged to administer oral rehydration therapy with polyionic solutions.

Results: Animals particularly cattle returning from common grazing area with full of thirsty (temperature reaches 40°C in hot summer) tense towards drinking of liquid. This situation conjugates this research work as edible oil intoxication. The clinical signs in peanut oil intoxication are anorexia from day one onwards, ruminal atony, cessation of rumination, dehydration, diarrhea initially which turned to semi solid in consistency with mucus shreds, perineal pasting, heavy fetid smell of dung, dull and depressed. After four days a (2141/14) animal developed cud dropping. Another animal (4721/14) had ataxia and tremor in fore quarter muscles. Sesame oil intoxicated animal had anorexia, dehydration, severely congested mucus membranes, ruminal atony, semisolid oil mixed dung, staggering gait from fifth day onwards and after 7days animal went for recumbence, inanition and cachexia. Coconut intoxicated animal had transient anorexia followed by varying degree of appetite, mucus and oil coated dung and latter diarrhea. All the animals had neutrophilia and leukocytosis. Peanut oil intoxicated bullock (2141/14) recovered completely after 15 days of therapy. No clinical recovery was noticed inspite of intense therapy after a week in a heifer (5916/14). It was sent to emergency slaughter. Another peanut intoxicated animal died on the next day of intoxication which had ataxia (4721/14). Sesame oil intoxicated animal died after 19 days. Owner discontinued therapy after 13 days because of frustration. Complete recovery noticed after 4 days of therapy in coconut oil intoxication.

Conclusions: This research concludes severity of illness was more in peanut and sesame oil intoxication. The major clinical signs were anorexia, cessation of rumination, ruminal atony, watery to semi solid diarrhea with mucosal shreds in the dung, dehydration and inanition. No protozoal activity was observed in rumen fluid of peanut oil intoxicated animals. The unsaturated fatty acids might be toxic to the mucosal epithelial cell membrane resulting in the denudation of intestinal epithelium. Adequate fluid and electrolytes, sodium bicarbonate, gut transplantation and broad spectrum antibiotics will help in clinical recovery of oil intoxicated animals.

Migration of *Fasciola hepatica* Newly Excysted Juveniles Is Inhibited by High- and Oligomannose-Type N-Glycan Binding Lectins In Vitro

Andres Garcia-Campos^{1,2,*} Joanne Heade^{1,2} Joseph Brady¹ Alan W. Baird^{1,2} Grace Mulcahy^{1,2}

¹School of Veterinary Medicine, ²Conway Institute of Biomedical and Biomolecular Research, University College Dublin, Belfield, Ireland

Objectives: *Fasciola hepatica* infection has major economic impacts on cattle production worldwide. In the host, following ingestion of metacercariae, the Newly Excysted Juveniles (NEJ) hatch in the small intestine, attach to the enterocytes and migrate through the intestinal wall until they reach the peritoneal cavity. Although the importance of selected molecules in NEJ invasion is known, many relevant proteins secreted by the NEJ are glycosylated, and the role of host and parasite-derived glycans in this process is not. Therefore, the aim of this work is to assess the differences in the migration rate of the NEJ after blocking different glycan subsets.

Materials and Methods: *F. hepatica* NEJ were hatched in vitro and incubated for 90 min with one of eight biotinylated lectins (ConA, GNL, PNA, Jacalin, UEA, LCA, PSA and WGA) that were chosen for their carbohydrate-binding affinities and ability to bind to glycoproteins in the NEJ tegument (NEJTeg) and soma (NEJSom). In parallel, distal jejunum from a euthanized rat was mounted in chambers in an in vitro system optimised for measuring the migration of NEJ across the intestine. Tissues in the chambers were incubated with lectin-incubated NEJ, and parasite migration through the intestine measured every 30 min up until 150 min. In addition, small batches of lectin-incubated NEJ were fixed in formalin solution at the beginning of the experiment, (T0) and at the end (T150). Fixed NEJ were embedded in paraffin for histological analysis to confirm positive lectin-glycan binding. In a second experiment, rat jejunal tissues were incubated for 60 min with the lectins WGA, GSL-I or UEA. Lectins were chosen according to their ability to bind to intestinal tissue. The lectin-incubated chambers were then incubated with *F. hepatica* NEJs.

Results: Incubation of NEJ with lectins binding to high and oligomannose-type N-glycans (ConA and GNL) significantly inhibited NEJ migration from 90 min till the end of the experiment. Histochemistry performed on sections of lectin-incubated NEJ showed that ConA and GNL did not bind to NEJSom but bound to the NEJTeg and the oral and ventral suckers from T0 to T150 min. Migration rates of the rest of lectin-incubated NEJ were not significantly different from those of the untreated group. WGA-, GSL-I- and UEA-incubated jejunal tissues did not affect the NEJ migration trend.

Conclusions: We concluded that the blockage of high and oligomannose-type N-glycans on *F. hepatica* NEJ with lectins significantly inhibited the migration of the juvenile flukes through the intestine in vitro. The development of drugs or vaccines that could mimic these inhibitory effects of ConA and GNL lectins could provide potential novel tools for the control of fasciolosis.

In vitro and in vivo evaluation of the herbal complex against trichostrongylid nematodes of sheep

Muhammad Arfan Zaman^{1,2,*} Zafar Iqbal³ Muhammad Fiaz Qamar⁴ and Anthelmintic

¹Microbiology, Cornell, Ithaca, NY, United States, ²Parasitology, University of Veterinary and Animal Sciences, Lahore, Lahore, ³Parasitology, University of Veterinary and Animal Sciences, Lahore, Faisalabad, ⁴Pathobiology, University of Veterinary and Animal Sciences, Lahore, Lahore, Pakistan

Objectives: Scientific validation of a herbal complex (HC), based on aqueous extracts of *Azadirachta indica* leaves, *Calotropis procera* flowers and *Trachyspermum ammi* seeds which have been used empirically as anthelmintic against trichostrongylid nematodes of sheep.

Materials and Methods: In vitro, eggs and adult *H. contortus* were exposed to different concentrations of HC following the standard procedures of egg hatch test (EHT; 50 to 0.024414 mg ml⁻¹) and adult motility assay (AMA; 200-0.1953125mg ml⁻¹), respectively. The reference drugs used in the study were oxfendazole (0.0056704 to 0.0000027 mg ml⁻¹) and levamisole (1.50 mg ml⁻¹) for EHT and AMA, respectively. In vivo, pre-and post-treatment (4 mg, 2 mg and 500 µg kg⁻¹ body weight) fecal egg counts were determined following standard fecal egg count reduction test in sheep naturally parasitized with mixed species of gastrointestinal nematodes.

Results: In EHT, LC₅₀ values of HC and oxfendazole (reference drug) were 275.1 and 0.016 µg ml⁻¹, respectively. In AMA, 100% mortality of *H. contortus* was observed 6 hrs post- exposure to 3.125-200 mg ml⁻¹ concentrations of HC and 2 hrs post-exposure to levamisole. In vivo, maximum (96.2%) fecal egg count (EPG) reduction was recorded in sheep treated with HC @ 4 mg kg⁻¹ body weight; whereas, 89.3% reduction in EPG was recorded in sheep treated with levamisole @ 7.5 mg kg⁻¹ body weight. The results of higher doses of HC were comparable with the reference drugs.

Conclusions: A graded dose response of HC in all the tests used in present study exhibits anthelmintic activities of the HC and justifying its traditional use as anthelmintic. Further, this study provides base-line information for future steps of drug development on commercial basis.

P04-004-063

Tolfenpyrad Insecticide Cattle Ear Tags: New Chemistry for Horn Fly *Haematobia irritans* control on cattle

Douglas Ross^{1,*}

¹Bayer Animal Health, Shawnee, Kansas, United States

Objectives: The objective of these studies was to evaluate efficacy of a tolfenpyrad cattle ear tag formulation (Tolfenpro™) for horn fly (*Haematobia irritans*) control on cattle. Tolfenpyrad, a new insecticidal active ingredient, belongs to the “mitochondrial electron transport inhibitor” (METI) mode of action (MOA) group [Insecticide Resistance Action Committee (IRAC) Group 21]. It represents a novel MOA for

ectoparasite control on cattle, and new rotational option for insecticide resistance management and horn fly control.

Materials and Methods: Five field studies were conducted in Missouri, Oklahoma and Texas (USA) in 2012-2013. Studies followed similar protocols, with each using five groups of cattle with 10 or 15 animals per group. In each study, one group served as a negative control (no ear tag treatment), and the other four groups received ear tag treatments. The tolfenpyrad ear tag formulation was compared to commercial ear tags containing active ingredients from three other IRAC MOA groups: avermectins (IRAC Group 6; XP 820™ - 8% abamectin + 20% piperonyl butoxide [PBO]); organophosphates (IRAC Group 1B; Corathon® - 15% coumaphos + 35% diazinon); and two pyrethroids (IRAC Group 3; PYthon™ Magnum® - 10% zeta-cypermethrin + 20% PBO and CyLence Ultra® - 8% beta-cyfluthrin + 20% PBO).

Following pretreatment fly counts animals were treated with the ear tag formulations, and horn flies were counted at approximately weekly intervals for up to 21 weeks post-treatment. Study duration varied with location and year; all studies were terminated when horn fly counts on treated animals were equal to or greater than counts on control animals.

Data were evaluated using two approaches. First, the weekly post-treatment fly counts were used to determine each ear tag's duration of efficacy, defined as the number of weeks for which the ear tag treatments reduced horn fly counts $\geq 90\%$, compared to the untreated controls. Second, the cumulative total numbers of horn flies counted on each animal during each study were analyzed to determine the overall reduction in fly pressure resulting from the ear tag treatments.

Results: The duration of efficacy ($\geq 90\%$ reduction in weekly average horn fly counts) varied substantially within and between studies. The average (range) numbers of weeks of efficacy for the five ear tag formulations were: tolfenpyrad 14 (8 - 21); abamectin + PBO 13 (9 - 21); coumaphos + diazinon 13 (9 - 16); zeta-cypermethrin + PBO 9 (5 - 17); and beta-cyfluthrin + PBO 8 (0 - 19).

All five ear tag formulations significantly reduced overall horn fly pressure ($p < 0.05$), compared to the untreated control animals. Across all five studies the average (range) percent reductions in cumulative horn fly numbers were: tolfenpyrad 79% (67 - 91%); abamectin + PBO 79% (63 - 90%); coumaphos + diazinon 73% (63 - 83%); beta-cyfluthrin + PBO 66% (56 - 85%); and zeta-cypermethrin + PBO 64% (31 - 81%).

Conclusions: Tolfenpyrad efficacy against *H. irritans* was comparable or superior to avermectin, organophosphate and pyrethroid products. These results indicated that tolfenpyrad's MOA represented a significant addition to other chemistries available for horn fly control and resistance management. Furthermore, tolfenpyrad has not been used extensively in crop protection, thereby reducing the risk of inadvertent horn fly exposure.

Bayer has obtained U.S. Environmental Protection Agency registration for this tolfenpyrad ear tag (Tolfenpro) for horn fly control on beef and dairy cattle, and is evaluating development potential in additional countries.

Association between rumen fluke and liver fluke prevalence in ruminants in Ireland

Amalia Naranjo Lucena¹·Guy McGrath¹·Laura Garza¹·Sean Hogan²·Barbara Good³·Annetta Zintl¹·Amanda Lawlor¹·Grace Mulcahy¹

¹UCD Veterinary Sciences Centre, University College Dublin, Dublin,

²Paralabs, Portumna, Galway, ³Animal & Grassland Research and Innovation Centre, Teagasc, Athenry, Co. Galway, Ireland

Objectives: Diagnostic laboratories in Ireland and the UK have reported an increase in the presence of rumen fluke (*Calicophoron daubneyi*) eggs in faecal samples submitted from both cattle and sheep starting in the late 2000's. As *C. daubneyi* is believed to share the intermediate snail hosts, *Galba truncatula* and *Lymnaea glabra*, with the liver fluke (*Fasciola hepatica*), the two fluke species are expected to co-occur. This epidemiological study was undertaken to investigate whether co-infections in ruminants are correlated geographically and/or seasonally.

Materials and Methods: Information on the presence and absence of liver and rumen fluke eggs in bovine, ovine, equine and caprine diagnostic faecal samples during 2012, 2013 and 2014 was provided by ParaLabs Ltd, the diagnostic laboratories of the Veterinary School in UCD and the Regional Veterinary Laboratories in Ireland. Statistical analysis was conducted to investigate the seasonality of both parasites and any possible association between them. Additionally, infection rates in the various host species were compared. Finally, the geographical distribution of both parasites across Ireland was examined using Geographical Information System (GIS) tools.

Results: There was a moderate association between rumen fluke and liver fluke as co-infections of the two were widespread supporting the hypothesis of shared intermediate hosts. However, there were significant differences in the distribution of the two flukes in the various host species, most notably a higher infection rate of rumen fluke in cattle while prevalence for both parasites in sheep was similar. The seasonal distribution of the two parasites varied from year to year with annual peaks in winter or spring.

Conclusions: Differences in fluke distributions are likely to reflect drug use and treatment schedules commonly used in the various host spp, but may also be due to differences in the availability of intermediate snail hosts in areas. Variations in the seasonality of both diseases may be related to changes in climatic conditions from year to year and may influence the risk of infection overall. Considering the co-occurrence of the 2 fluke species it is important to determine whether one can exacerbate the clinical effects of the other.

Outbreak of bovine trypanosomiasis due to inadequate pre-milking management in the state of Goiás, Brazil

Paulo H. J. Cunha¹·Thiago S. A. Bastos¹·Antônio D. F. Noronha Filho¹·Luciana C. Bessa¹·Adelly C. Mota¹·Helena T. Dutra¹

¹Veterinary Medicine Department, Federal University of Goiás, Goiânia, Brazil

Objectives: Trypanosomiasis is one of the world's most important human and livestock disease. In this paper, we report an outbreak of bovine trypanosomiasis occurred in the month of September 2015 in Goiás State, Brazil, that involved an infection with *Trypanosoma vivax* in dairy cattle.

Materials and Methods: The outbreak reported here occurred on a dairy farm with 418 Girolando animals, in a semi-intensive production system. The farmer manager was interviewed in order to obtain information about health problems of the herd, movement of animals into and out

from the farm and others risk factors that might have contributed towards the spread of the disease. From a total of 418 cattle, 67 cows showing clinical signs were examined and blood samples were collected from the jugular vein for direct observation of fresh blood samples.

Results: As reported by the farm manager many of the cows were bought in others states (Sao Paulo e Minas Gerais) and a total of 40 cows died. The main factors involved in the spread of the disease were: the entry of animals without prior tests and quarantine and the cows received daily 5 IU of oxytocin before milking, to assist in milk let-down, which was injected on the cranial superficial epigastric vein, using the same needle and syringe in all animals. They never observed any large population of tabanids, which are the flies implicated as the main vectors of *T. vivax* in South America. *Haematobia irritans* and *Stomoxys calcitrans* weren't detected during all the visits to the farm. From a total of 418 cattle, 67 (16%) showed signs of anemia, lethargy, weakness, general weight loss, hyperthermia, anorexia, reduction in milk production, abortion and retained placenta. The protozoan was observed microscopically in 36 (8.61%). No other blood parasites, such as *Babesia* sp. and *Anaplasma marginale*, were observed in the microscopic exam.

Conclusions: Iatrogenic transmission through inappropriate application of intravenous medication in the pre-milking management, associated with the acquisition of animals of unknown origin, may be grounds for rapid spread of bovine trypanosomiasis in a dairy herd.

Identification of *Sarcocystis tenella* (Protozoa: Apicomplexa) in Korean Native Goat from Korea

Eui-ju Hong¹ Si-yun Ryu¹ Joon-Seok Chae² Hyeon-Cheol Kim³ Jinho Park⁴ Kyoung-Seong Choi⁵ Do-hyeon Yu⁶ Bae-Keun Park⁷ Cho Jongki⁸

¹College of Veterinary Medicine, Chungnam National University, Daejeon 34134, ²Laboratory of Veterinary Internal Medicine, BK21 Plus program for Creative for Veterinary Science Research, Research Institute of Veterinary Science and College of Veterinary Medicine, Seoul National University, Seoul 08826, ³College of Veterinary Medicine, Gangwon National University, Chuncheon 24341, ⁴College of Veterinary Medicine, Chonbuk National University, Iksan 54596, ⁵College of Ecology and Environmental Science, Kyungpook National University, Sangju 37224, ⁶College of Veterinary Medicine, Chonnam National University, Gwangju 61186, ⁷College of Veterinary Medicine, Chungnam National University, Daejeon 37224, ⁸Chungnam National University, Seoul, Korea, Republic Of

Objectives: *Sarcocystis* species are common parasites with a wide range of hosts and obligatorily intracellular protozoa. There are three species of *Sarcocystis* in domestic goats: *S. capracanis*, *S. hircicanis* and *S. capraefelis* (syn. *S. moulei*). *S. capracanis* and *S. hircicanis* produce microscopic sarcocysts while *S. capraefelis* produces macroscopic cysts. *S. capracanis* is the most pathogenic species in goats, causing fever, weakness, anorexia, weight loss, tremors, irritability, abortion and death. In this study, we report the natural infection of *S. tenella* in Korean native goat for the first time.

Materials and Methods: A total of 103 cardiac muscle samples of Korean native goats, *Capra hircus coreanae*, were obtained from January to August, 2014 in slaughterhouse located in Wonju city, the Republic of Korea. The specimens were examined histologically analyzed by light microscopy (LM), transmission electron microscopy (TEM), and complete 18S rRNA gene product obtained by polymerase

chain reaction (PCR) was sequenced and phylogenetically analyzed. Genomic DNA was next extracted from frozen positive samples identified by light microscopic method. Genomic DNA extraction was carried out using DNeasy Blood & Tissue Kits (Qiagen, Hilden, Germany) according to manufacturer's instruction. The PCR products were next visualized via electrophoresis on 1.2% agarose gel with SiZer™-100 DNA marker (Intron, Seongnam, Korea) and purified using Nucleospin® Gel and PCR Clean-up (Macherey-Nagel, Düren, Germany) for sequencing.

Results: To investigate the prevalence of *Sarcocystis* sp. in the Korean native goat, the heart tissues were analyzed using H&E staining. Of the 103 goats, 3 goats were diagnosed as sarcocysts positive, and they are identified with *S. tenella* using H&E staining, electron microscopic analysis and genomic DNA sequencing. The incidence of *Sarcocystis* infection is low (2.91%) in the slaughtered goat. Using a transmission electron microscopy, the sarcocysts are identified with *S. tenella*. Moreover, DNA and phylogenetic analysis confirmed our identification of *S. tenella* using 18S rRNA gene sequencing.

Conclusions: Of the 103 goats, 3 (2.91%) were diagnosed as positive for *S. tenella* by light, electron microscopic and molecular examination. The histopathological study showed a low frequency of microscopic *Sarcocystis* infection in slaughtered goats. In transmission electron microscopy, the sarcocysts were confirmed as *S. tenella*. Further DNA sequencing and phylogenetic analysis support our identification of *S. tenella* with the sequence identity of 18s rRNA between the experimental sequence and *S. tenella* with 100%. This is a first record of *S. tenella* in Korean native goat from Korea.

Targeted selective treatment of gastrointestinal nematodes based on live weight gain variations in first-season grazing dairy calves in Ireland

Katell Delaby¹ Emer Kennedy² John P. Murphy² Riona Sayers^{3,*}

¹Oniris, Ecole Nationale Vétérinaire, Agroalimentaire et de l'Alimentation Nantes Atlantique, 44307 Nantes Cedex 3, France, ²Livestock Systems, ³Animal & Biosciences, Teagasc, Moorepark, Fermoy, Co. Cork, Ireland

Objectives: As anthelmintic resistance is increasingly evident in cattle populations, targeted selective treatment (TST) strategies are aimed at ensuring a more responsible use of anthelmintic molecules. The aim of the current study was to investigate the ability of TST in first-season grazing Irish dairy calves to 1) limit gastrointestinal nematode infection levels, reduce anthelmintic use and maintain animal performance, and 2) be practical and resource efficient (i.e. farmer-friendly), when implemented under Irish environmental conditions and grazing management practices.

Materials and Methods: The experiment was conducted at Teagasc, Moorepark (Co. Cork, Ireland). The study period began 6th May 2015 for a period of three months. Calves were rotationally grazed over the course of the experiment. Prior to treatment, 110 female dairy calves born between 22nd January and 18th February 2015 were randomised by breed, date of birth, body weight at trial initiation and live weight gain (LWG) to one of three anthelmintic treatment strategies; no treatment (NT, n=10), group treatment (GT, n=50) and targeted selective treatment (TST, n=50). The NT group received no anthelmintic treatment over the course of the study to allow determination of the overall nematode challenge. A prophylactic injection of long-acting moxidectin was

administered to the GT group on 6th May (Cydectin® 10% LA, Zoetis) as per routine nematode management on the farm. Treatment of TST calves was based on two LWG criteria and one health criterion. Live weight gain was assessed every second week and calf health was scored twice weekly (including faecal score). A TST calf (1) failing to reach a LWG threshold set at 20% below the LWG average of its grazing group, or (2) showing a LWG below 0.56 kg/day (i.e. 20% below an optimum of 0.70 kg/day), or (3) with diarrhoea (faeces score of 3/3 on two consecutive occasions) received anthelmintic treatment within one week. For monitoring purposes, faecal samples were collected every month for gastrointestinal nematode faecal egg count (FEC) determination. Descriptive data were collated and analysed in MS Excel (2010).

Results: Of the 50 calves in the TST group, 16, 4, 8, and 1 were treated within 10, 31, 46, and 65 days of trial start date, respectively. In all, therefore, 60% of the TST group required dosing. Those calves in the TST group that required treatment were dosed on the basis of failing to meet LWG criteria. No calf was treated on the basis of a poor faeces score. No difference in body weight at the end of the trial period (150 vs. 152 kg; $P=0.41$) or overall LWG over the duration of the trial (0.68 vs. 0.70 kg/day; $P=0.42$) was recorded between TST and GT groups. The worm challenge experienced over the course of the study was moderate, with a mean FEC of 158 eggs per gram (range 0 to 700 eggs per gram) in NT calves after 120 days of grazing. No difference in FEC was observed between TST and GT calves.

Conclusions: This study demonstrated that in Ireland, gastrointestinal nematode parasitism of first-season grazing dairy calves could be controlled using a TST strategy without any significant effect on calf performance. It must be stated, however, that only 40% of TST calves remained undosed. The economic benefit of reducing anthelmintic use was, however, far outweighed by the resources (labour, equipment, diagnostics) required to effectively implement a TST programme without compromising calf health. The practicality of implementing such an approach in grass-based systems such as exists in Ireland, therefore, is highly questionable currently.

Parasitology

P04-004-068

Prevalence of non-*Tritrichomonas foetus* trichomonads in preputial samples from Nebraska beef bulls

Jeff Ondrak¹; Robert A. Cushman²

¹University of Nebraska-Lincoln, ²USDA, ARS, U.S. Meat Animal Research Center, Clay Center, NE 68933, United States

Objectives: Bovine trichomoniasis is a venereal disease of cattle found throughout the world caused by *Tritrichomonas foetus*. Control programs rely on detection and removal of carrier bulls. Non-*T. foetus* trichomonads may lead to false positive microscopic examinations. False positive PCR results due to non-*T. foetus* trichomonads are less likely; however PCR inaccessibility and cost may prevent its use. The purpose of this study was to determine the prevalence of non-*T. foetus* trichomonads in the preputial samples from a herd of Nebraska beef bulls to allow diagnosticians to make informed interpretations of culture results.

Materials and Methods: Preputial specimens were collected from all bulls in a single herd with no history of trichomoniasis. The bulls were of various breeds and ranged in age from one to five years and were sexually rested for at least four months prior to sample collection using a

previously described dry pipette technique. All samples were inoculated into a commercially available plastic pouch containing culture medium immediately after collection and maintained at room temperature until placed in an incubator within four hours of collection. Inoculated pouches were incubated upright at 37°C for four days. Pouches were systematically examined daily for the presence of trichomonads by an experienced veterinarian using light microscopy starting 24 hours after collection and continuing through the fourth day after collection. Pouches were classified as positive if live protozoa of a size, morphology, and motility pattern consistent with trichomonads were seen on at least one of the five days. After the microscopic examination on the fourth day all culture positive pouches were submitted for gel PCR testing using *T. foetus* specific and pan trichomonad primers according to the laboratory's standard protocols.

Commercially available software was used to calculate the prevalence and 95% confidence interval of non-*T. foetus* positive samples.

Results: Three hundred and fifty-two bulls from one to five years of age were sampled and produced three culture positive, *T. foetus* PCR negative, pan trichomonad PCR positive samples resulting in an overall non-*T. foetus* prevalence of 0.85% (95% CI, 0.29% to 2.48%). All three positive samples were from yearling bulls resulting in a non-*T. foetus* prevalence of 2.0% (95% CI, 0.68% to 5.71%) for this age group of 150 bulls. All 202 bulls two years of age and older were culture negative resulting in a non-*T. foetus* prevalence of 0.0% (95% CI, 0.0% to 1.87%) for this age group.

Conclusions: The current study supports the assumption young bulls are more likely to harbor non-*T. foetus* trichomonads than older bulls. Although no older bulls were test positive in this study the 95% confidence interval indicates the true prevalence is less than that of yearling bulls, but not necessarily zero. Therefore, preputial samples tested for *T. foetus* by culture should be confirmed as truly *T. foetus* positive by other testing procedures as indicated by pretest factors such as herd and bull history, bull age, and the estimated prevalence of non-*T. foetus* trichomonads.

USDA is an equal opportunity employer.

P04-004-069

Generation of resistance reversion to Macroyclic Lactones in cattle throughout epidemiological and refugia principles

Cesar Fiel¹; Pedro Steffan¹; Arturo Almada²; David Homer³

¹Faculty of Veterinary Science, National University of the Centre of Buenos Aires Province – UNICEN, Argentina, Tandil, ²Technical Services, Merial LA & VPH, Buenos Aires, Argentina, ³Head of Technical Services, Merial LA & VPH, Lyon, France

Objectives: Nematodes that are not exposed to anthelmintic are known as refugia. Appropriate usage of refugia is reported to assist in slowing the rate of resistance development by diluting the genetic significance of the resistant worms surviving in animals after treatment.

The objective of this study was to determine if quantifiable, well-timed and appropriate dilution could quickly create an improvement in efficacy of the ML family and, if so, collect a dataset that could be used to improve our understanding of just how much refugia is enough to make meaningful changes in established (or developing) resistance levels in nematode populations.

Materials and Methods: A farm in Argetina was selected, based on it having a 2012 Fecal Egg Count Reduction Test (FECRT) result for Ivermectin (IVOMEC®, injection at 200 mcg/kg) against *C. oncophora* of 74.7%. A single paddock (65 hectares) on this farm was used for this study. The overall design was to inoculate ML susceptible *C. oncophora* into calves at a time of the year when larval survival on pasture was normally at its lowest (late Summer) and to then graze these cattle on a paddock with established resistance.

Eighty-two, 6-month old Aberdeen Angus heifer calves were treated with a Levamisole subcutaneous injection (Ripercol®, 7.5 mg/kg) and then 7 days later were inoculated orally with 20,000 L3 of *C. oncophora*. 14 days later, the oral challenge of L3 was repeated and the cattle were then placed on the test paddock (March 2013 - Autumn). Tracer calves were also placed in the paddock in Autumn and again later in Spring, with both groups being subsequently treated with Ivermectin (IVM) and subjected to post-treatment worm counts to determine Macrocytic Lactone (ML) efficacy. An IVM FECRT was also conducted on the 82 calves in November (late Spring). At monthly intervals feces from animals and pasture grass samples were collected. Rainfall levels at the farm were also recorded.

Ripercol® is a registered trademark of Zoetis. IVOMEC® is a registered trademark of Merial Inc.

Results: The efficacy of Ivermectin against *C. oncophora* in the Tracer Calves were 39.1% in Autumn and 75.7% in the following Spring (Worm Kill results). The FECRT performed on permanent grazing heifers at the end of the spring showed a clinical efficacy overall of 95% with *Cooperia* spp. being the single worm species identified in post-treatment coprocultures. The FECRT result for *C. oncophora* was 61% but with a day 0 *Cooperia* spp. count of 28 eggs per gram. The pasture contamination level at initial placement in March was 125 L3 per kg dry matter. Fecal cultures and herbage infectivity indicated that contamination with nematode eggs throughout the study was clearly dominated by *Cooperia* spp. (> 50%). The levels of infective larvae were very low during winter and from September onwards an increase was recorded up to reach a peak of 1486 L3/k.d.g. in November.

Conclusions: It was not expected that the efficacy of Ivermectin would return to >95% after just 1 year, especially after seeing the very low efficacy recorded in tracer calves in Autumn (39.1%). By the end of the year the worm kill result had well improved (75.7%). Despite a low level of herbage infectivity at beginning of the study (125 L3 per kg dry grass) it was possibly high enough (combined with concurrent rain events) to ensure that meaningful dilution of the resistant worm population was going to be difficult to quickly achieve. It is expected that repeating this process over the next few years will further improve the efficacy levels.

Parasitology

In vitro and in vivo, acaricidal activity of a herbal formulation against cattle tick (*Rhipicephalus microplus*)

Muhammad Arfan Zaman^{1,*}

¹Parasitology, University of Veterinary and Animal Sciences, Lahore, Lahore, Pakistan

Objectives: Evaluation of anti-tick activity of a herbal formulation (HF) based on aqueous extracts of *Azadirachta indica* and *Nicotiana tabacum*

leaves, *Calotropis procera* flowers and *Trachyspermum ammi* seeds against cattle tick *Rhipicephalus* (*Boophilus*) *microplus*.

Materials and Methods: Eggs, larvae and adults of *R. microplus* were subjected to various doses of HF (Deionized water). In vitro, 10 adult blood engorged female ticks were immersed in various dilutions of HF (Adult Immersion Test (AIT); 50 - 6.25 mg ml⁻¹) and 100 larvae exposed to HF (Larval Packet Test (LPT); 50 - 0.78125 mg ml⁻¹) through impregnated filter papers. In vivo, twelve calves (n=12; local breed) were infested with unfed larvae (14 days old) in ear bags (13 × 17 cm; 110-130 larvae/bag) tied on the base of ear pinnae. After 24 hrs of the larval attachments, three animals (replicates) for each suspension of HF (15%, 30% and 45%) were treated topically on the tick infested body parts for 6 consecutive days, twice-a-day.

Results: The HF demonstrated anti-tick activity by inhibiting the fecundity of the female ticks, hatching percentage of eggs, larval mortality and reduced tick intensity/infestation on animals. In vitro, lethal effects on egg laying (index of egg laying = 0.371404 ± 0.00435), hatching (22.35%) and 100% larval mortality were recorded at 50 mg ml⁻¹. In vivo, the HF reduced tick intensity significantly on the infested calves (18 detached out of 35) at 45% (w/w) suspension, applied topically on the infested skin.

Conclusions: A graded dose- and -time dependent response of the HF in this study, against all developmental stages of *R. microplus* indicates potential of the HF as a botanical acaricidal. Study of toxicity of the HF on exotic breeds of cattle, however, is recommended.

Identification Of Enteropathogens From Murrah Buffalo Calves

Damazio C. Souza^{1*} Daniela G. Silva¹ Bruno M. Monteiro¹ Heloisa P. D. G. Siqueira² Ingrid B. Affonso² Thaís G. Rocha¹ José H. Tebaldi² Estevam G. L. Hoppe² Rinaldo B. Viana³ Maria G. Buzinaro² José J. Fagliari¹

¹Departamento de Clínica e Cirurgia Veterinária, ²Departamento de Medicina Veterinária Preventiva e Reprodução Animal, Faculdade de Ciências Agrárias e Veterinárias - FCAV - Unesp - Jaboticabal, Jaboticabal, ³Instituto de Saúde e Produção Animal, Universidade Federal Rural da Amazônia, Belém, Brazil

Objectives: The present study aims to assess the occurrence of endoparasites and rotavirus in fecal samples from a dairy property of Murrah buffalo calves from different ages, and assess the presence of rotavirus in those animals.

Materials and Methods: There were collected fecal samples from ninety one Murrah buffalo calves distributed in the following groups: G1: 0-30 days old (n=7); G2: 31-60 days old (n=14); G3: 61-90 days old (n=4); G4: 91-120 days old (n=6); G5: 121-150 days old (n=9); G6: 151-180 days old (n=9); G7: 181-210 days old (n=15); G8: 211-240 days old (n=15); G9: 241-270 days old (n=7); G10: 271-300 days old (n=5). All fecal samples were inspected to determine the absence or presence of diarrhea. The research was made in a dairy farm located in the city of Alambari located in the State of São Paulo, Brazil. The samples were collected directly from the rectum using plastic hand gloves and identified with the animal number and age, then they were preserved at 4°C until the analysis. The parasitological analysis were made according to the Gordon &

Whitlock modified technique and the identification of rotavirus by polyacrylamide gel electrophoresis (PAGE) technique following silver nitrate stain.

Results: Twenty calves of the total examined (21.98%) had diarrheal feces. Seventy eight of the ninety one samples (85.71%) were positive for *Eimeria* sp., with more prevalence in G2 and G6. Sixty six of the total samples (72.57%) were found positive for Strongylida, with only one positive animal in G2 and the higher infestations on the G5 (average value of 1,083 EPG count). Three samples were positive for *Moniezia* sp. (3.30%), one belonging from the G4 (91-120 days old) and two others belonging to the G5 (121-150 days old). Only two of the ninety one samples (2.20%), those belonging to the G2 (31-60 days old), were positive for *Neoscaris* sp. None of the samples was positive to rotavirus in PAGE technique.

Conclusions: The more frequent enteropathogens observed in buffalo calves were *Eimeria* sp., Strongylida, *Moniezia* sp., and *Neoscaris* sp., with *Eimeria* sp. being the most occurrent of the studied enteropathogens in the calf phase.

Lasalocid supplementation and its effect on the control of *Eimeria* spp. parasitism in naturally infected Nellore calves in a tropical area of Brasil

Leonardo B. Cruvinel¹Luri Vladimir Pioly Marmitt^{2,7}Andressa L. Ranieri³Fernando A. Borges⁴Welber D. Z. Lopes¹Antonio R. Pacheco⁵Samuel R. Félix²Sergio S. Silva²Elio Moro³

¹Faculdade de Veterinária, Federal University of Goiás, Goiania, ²LADOPAR, Federal University of Pelotas, Pelotas, ³Zoetis Animal Health, São Paulo, ⁴Federal University of Mato Grosso do Sul, Campo Grande, ⁵Field Veterinary, Goiania, Brazil

Objectives: The aim of this study was to assess the efficacy of lasalocid (1mg.kg⁻¹) administered over four months along with the protein and energy supplementation of calves, in a creep-feeding system, in the control of asymptomatic *Eimeria* spp. parasitism. This work also evaluated animal weight gain under the different treatment schemes.

Materials and Methods: Two hundred and eighty Nellore calves of both sexes, aging from four to six months, were randomly divided in two groups. Group one (T01) was comprised of 138 calves, and had a mean *Eimeria* oocyst count per gram of feces (OoPG) of 690.9 per animal. Group two (T02) was comprised of 142 animals, with a mean oocyst count of 692.2 OoPG. Both groups were supplemented in a creep-feeding scheme with a protein and energy concentrate. While animals in T01 had no further supplementation, those in T02 received 1.3 grams of lasalocid, mixed in the concentrate feed, for every 200 Kg body weight. Treatment begun two months prior to weaning, and continued for two months after weaning, during this period animals were assessed monthly through fecal oocyst counts (McMaster method), and weighed, to assess weight gain. To minimize competing effects from gastrointestinal nematodes, all calves were treated with moxidectin (200µg/kg) every 45 days. Mixed model procedure was used for the statistical analysis

Results: Regardless of the age of the animals, the calves of T02 (treated with lasalocid 1mg.kg⁻¹), showed a significant (P<0.05) reduction of oocyst shedding per gram of feces in comparison to the control group, as early as one month after treatment started. This reduction, compared to the control, continued in all dates post-treatment. The efficacy rate above 95% (arithmetic means) was observed up to the 60th day after weaning. Furthermore, animals belonging to the T02 had an increase in weight gain throughout the period of 7.2 kg (p<0.05), in comparison with the control animals (T01).

Conclusions: In conclusion, lasalocid (1mg.Kg⁻¹) administered during one month was enough to reduce significantly (p<0.05) the number of oocysts dispersing to environment. The four months addition of lasalocid was able to maintain the reduction of oocyst shedding per gram of feces. The control of these protozoan infections provides a significant increase in weight gain in comparison to untreated animals. This protocol could be recommended as a management tool to reduce the environmental dispersion of oocysts of *Eimeria* spp. minimising risks of reinfection, promoting an increase of health pattern.

Fipronil and Fluzuron: efficacy of a novel combination against *Dermatobia hominis* and *Cochliomyia hominivorax* in naturally infested cattle

Welber D. Z. Lopes^{1,1}Rafael M. Chiummo²Emerson M. Botelho²Luis F. Vettorato²

¹Instituto de Patologia Tropical e Saúde Pública, Universidade Federal de Goiás, Goiânia, GO, ²MSD Saúde Animal, São Paulo, Brazil

Objectives: The efficacy of a new pour-on formulation comprising the anti-Parasiticides Fipronil (1.25 mg/ kg) + Fluzuron (2.5 mg/ kg) was evaluated in two field studies against *Dermatobia hominis* (Experiment 1) and *Cochliomyia hominivorax* (Experiment 2) in naturally infested cattle.

Materials and Methods: Experiment 1 was held on a farm in the municipality of São João da Boa Vista, São Paulo State, Brasil. In this study, 20 Canchim animals, naturally infested with *D. hominis* larvae (grubs) were randomly allocated into two groups of 10 animals each, based on nodule counts containing live larvae in the body of each animal on Day -1 pre-treatment: T01: Fipronil (1.25 mg/ kg) + Fluzuron (2.5 mg/ kg); T02: Saline 0.9% Control. After treatment, counts were carried on days 3, 7, 14, 21, 28, 35, 42 and 49 post-treatment.

Experiment 2 involved 12 calves divided into 2 groups of 6 animals. T01 was treated with Fipronil + Fluzuron and T02 was the control. Animals were randomly assigned to treatment groups, based on the individual weight measured at D-7. On day 0 (before treatment), each animal was subjected to two circular 4 cm skin incisions (one on each side of the body), between the infra-spinal cavity and the dorsal scapula border. This was done after sedation (dihydrotiiazine hydrochloride) and local anesthesia (lidocaine 2%). Right after the surgery, treatment from T01 was carried out. Immediately after treatments, the 2 groups were kept in separate adjacent pastures, allowing natural exposure to *C. hominivorax* infestations. To evaluate the preventive efficacy of the new formulation, the 24 incisions were examined daily from the 1st - 10th DPT. The larvae in the lesions were classified as active (at least one live *C. hominivorax* larvae / lesion), and identified by a specific record with digit 1 (active) or digit 0, (not active, no live larvae in the lesion).

Results: The combination of Fipronil and Fluzuron in experiment 1 demonstrated efficacy higher than 90% from the 7th to the 35th day post-treatment (DPT), showing 99.5% of efficacy on 21 and 28 DPT. In all post-treatment dates, the *D. hominis* larvae counts were statistically lower (p ≤ 0.05) in the animals from T01 when compared to the control animals (T02).

In experiment 2, from the 1st -10th DPT, the Fipronil + Fluzuron reached 100% of preventive effectiveness, preventing T01 animals to develop active myiasis in all lesions. The animals in the control group showed

active myiasis from the 2nd to the 5th DPT, after which they had to be treated for animal welfare reasons (using a commercially available topical organophosphate).

Conclusions: With the results of these two studies it is possible to infer that the new formulation containing Fipronil (1.25 mg / kg) + Fluzuron (2.5mg / kg), in the dose and route employed, proved high efficacy against *Dermatobia hominis* larvae and preventive efficacy against *Cochliomyia hominivorax* in naturally infested cattle.

Evaluation of the persistence of *Trypanosoma vivax* DNA after treatment with isometamidium hydrochloride

Paulo H. Sampaio¹* Otavio L. Fidelis Junior¹ Priscila P. Pereira¹ Kayo J. G. D. A. Castilho Neto¹ Marcos R. André¹ Rosangenla Z. Machado¹ Fabiano A. Cadioli¹

¹Faculdade de Ciências Agrárias e Veterinárias - UNESP/Jaboticabal, Jaboticabal, Brazil

Objectives: *Trypanosoma vivax* affects ruminants and equines in Africa, Central and South Americas, causing vast economic losses in affected herds. Clinical signs are unspecific and there are often aparasitemic periods that complicate diagnosis and treatment of affected animals. Treatment of ruminants infected with *T. vivax* is commonly performed with diminazene diaceturate (DM) and isometamidium hydrochloride (ISM), although resistance to both chemotherapy has been reported. This study aimed to evaluate the persistence of parasite DNA after treatment with ISM.

Materials and Methods: Three male goat (C1 to C3) experimentally infected with 2x10⁶ trypomastigotes of *T. vivax* were used. Blood collection was performed daily in D-2 and D-1 (pre-infection; PI), D1 to D14 (infected – Pretreatment; PRE) and D15 (treatment day) to D26 (infected – Post-treatment; POS). DNA extraction was performed using QIAamp DNAeasy Kit (Qiagen®), according to manufacturer's instructions and DNA stored at -20° C until use. Samples were subjected to cPCR that targets the gene cathepsin L-like enzyme (CatL) of *T. vivax* (Cortez et al., 2009) and to cPCR for the endogenous gene GAPDH (Birkenheuer et al., 2003).

Results: All samples were positive for cPCR to endogenous gene GAPDH, demonstrating the absence of reaction inhibitors and good quality of extracted DNA. On the other hand all PI samples were negative for cPCR to *T. vivax*. All PRE samples were positive for cPCR to *T. vivax*, confirming the infection. Parasite DNA was detected up to D24 (POS; nine days), but in alternate days and samples, being positive the C3 D16, C2 D17, C1 D18, C2 D18, C1 D21 and C2 D24 samples, other samples were negative for this test.

Conclusions: Our results indicate that the chemotherapy action on *T. vivax* is not immediate or that this hemoparasite may be resistant to this drug, which could favor the infection of others animals during this period.

Comments: We thank the São Paulo Research Foundation (FAPESP) for financial support - Process number - 2014/11600-1

Prevalence of *Tritrichomonas foetus* in bulls in The State of Chihuahua Mexico Tested with VetMAX™-Gold Trich Detection Kit

Everardo Gonzalez-Rodriguez¹ Alejandro Ramirez-Godinez¹ Beatriz A. Leal-Tarin¹ Cathia Lastra-González¹ Perla L. Ordoñez-Baquera¹ Jorge A. Álvarez-García¹ Eduardo Santellano-Estrada¹ Mario E. Esparza-Vela¹ Jeff Baxter² Ivan Leyva Baca^{2,*}

¹Facultad de Zootecnia y Ecología, Universidad Autonoma de Chihuahua, Chihuahua, Mexico, ²Animal Health, Thermo Fisher Scientific, Austin, United States

Objectives: The aim of this study was to perform a pilot study in collaboration with the Facultad de Zootecnia from the Universidad Autonoma de Chihuahua Mexico with the implementation of the MagMAX™ sample preparation system and the USDA licensed VetMAX™-Gold Trich Detection Kit to investigate the prevalence and risk factors of *T. foetus* in the State of Chihuahua.

Materials and Methods: Four hundred and fifty breeding bulls from the state of Chihuahua Mexico were sampled with the TrichIT pipette by gently rasping the bull's prepuce. Inoculation of InPouch™ Biomed with smegma samples was carried over with an incubation time of 24 hours at 37°C. Nucleic acid extraction and purification was performed using the 5X pathogen DNA/RNA extraction and purification kit from Thermo Fisher Scientific as outlined by the kit manufacturer, utilizing a magnetic particle processor. Three hundred µl of sample was used in the extraction process. Their PEC, which also served as an IPC, was implemented by spiking 20,000 copies per extraction with Xeno DNA^c into the lysis/binding solution used with each sample. Duplicates of a mock-purified sample referred to as the Xeno extraction control (XEC) were included in each plate processed. The XEC consisted of 300 µl of PBS processed in the same manner as the test samples. Final diagnostic calls were performed with the USDA licensed real-time PCR VetMAX-Gold Trich Detection Kit from Thermo Fisher Scientific.

Results: Results showed that from the 450 beef bulls tested, 113 were positive, which shows a prevalence of 25%. The high prevalence of *T. foetus* in the state of Chihuahua is similar to that reported in the mountains of Asturias in Spain (32%) in which cattle are managed in extensive pastoral systems where less than 2% of the matings are with artificial insemination (Mendoza-Ibarra et al., 2012). Differences of prevalence of *T. foetus* between the tested beef cattle breeds in this study were observed and may indicate possible resistant differences to the protozoa. In this sense several studies have shown that *Bos taurus* (beef) breeds have an increased risk to get infected when exposed to *T. foetus*, since they are up to six times more likely to get infected than *Bos indicus* breeds. The observed differences may be explained by the greater number of mounts performed by *Bos taurus* compared to *Bos indicus* in a similar time period, thus increasing the exposure of bulls to infected cows (Rae et al. 2004; Bondurant et al., 1990; Ortega-Mora et al., 1998). In addition we analyze age as a risk factor for the disease through the X² test, with an age range of 2-10 years. The data show that the differences observed in the presence of *T. foetus* and age was statistically significant (X² test, p < 0.001), in which bulls aged 10 years showed the highest percentage of parasite infection (78%).

Conclusions: The workflow of sample preparation with 5X MagMAX™ Pathogen RNA / DNA kit and real-time PCR-Gold VetMAX™ Trich Detection Kit, enabled the rapid and sensitive diagnosis of *T. foetus*. Its application allowed us to identify an important prevalence of the parasite (25%) in a population of beef bulls in the State of Chihuahua. Our data is consistent with others observed in similar beef production systems, where abortion control diseases through molecular diagnosis

is very limited or null. The urge to expand the diagnosis to control of *T. foetus* in the State of Chihuahua Mexico is demonstrated.

Assessment of *Theileria* infections in ticks collected from the field by staining with methyl green Pyronin and Azure methods

Ahmad Nematollahi¹*Saeed Rezaii¹

¹Pathobiology, University of Tabriz, Tabriz, Iran, Islamic Republic Of

Objectives: Ovine theileriosis is an important hemoprotozoal disease of sheep and goats in tropical and subtropical regions that leads to economic losses in these animals. A rapid method is described for preparing and staining salivary glands of ticks infected with *Theileria lestoquardi*. This study was carried out to comparing between two staining methods for detecting of theileriosis in salivary glands of ticks.

Materials and Methods: A total of 200 suspected cases of ovine theileriosis were clinically examined in Tabriz in northwest of Iran. The sheep were investigated for the presence of *Theileria lestoquardi* in appropriate blood smears and any ticks species on body of sheep. Blood smears were stained by Giemsa method. Totally 240 adult ticks were collected from sheep. In laboratory *Hyalomma anatolicum*, *H. marginatum* and *Rhipicephalus sanguineus* were diagnosed. These ticks were examined for infection with *Theileria* by two staining methods. Whole salivary glands were stained with methyl green pyronin and Azure methods.

Results: In this study, 42(21%) of sheep were infected to *T. lestoquardi*. Infection in male sheep was higher than female. The examination of tick salivary glands showed that (7.5%) of salivary glands of ticks were positive to *Theileria* sporoblasts in methyl green pyronin staining method and this rate in Azure staining method was (6.66%). The prevalence rate of *Theileria* infection was higher in female ticks than in males but the difference was not significant ($P < 0.05$) probably because of smaller sample size.

Conclusions: The results of this study observed that is not significant differences between two methods of staining of salivary glands in ticks for detecting of infection to theileriosis. Base on the results of this study other staining method for diagnosing of theileriosis in ticks such as molecular procedures are recommended.

Comments: Base on the results of this study other staining method for diagnosing of theileriosis in ticks such as molecular procedures are recommended.

Longitudinal survey of gastrointestinal parasitism in native cattle in the Central Dry Zone of Myanmar

Angus Campbell¹*, Jenny Hanks¹, Elsa Glanville¹, Thiri Zaw², Thae N. Nway³, Win M. Thein⁴, Yin Y. Myint⁵, Zin M. Latt³, Simon Quigley⁶, Soe M. Thein², Lwin N. Oo², Aung Aung², Kyaw N. Oo³, Dennis Poppi⁶

¹Mackinnon Project, Faculty of Veterinary & Agricultural Sciences, University of Melbourne, Werribee, Australia, ²University of Veterinary Science, Yezin, ³Livestock Breeding & Veterinary Department, Ministry of Livestock, Fisheries & Rural Development, Nay Pyi Taw, ⁴Livestock Breeding & Veterinary Department, Ministry of Livestock, Fisheries & Rural Development, Meiktila, ⁵Livestock Breeding & Veterinary Department, Ministry of Livestock, Fisheries & Rural Development, Myingyan, Myanmar, ⁶School of Agriculture & Food Science, University of Queensland, Gatton, Australia

Objectives: Myanmar is undergoing rapid social and economic change. It is very reliant on agriculture, and agricultural development offers pathways for rural poverty alleviation. Many households own cattle, typically for draught, but which could provide meat and/or milk to regional markets. Little is known of cattle endemic disease, particularly those with subclinical effects, such as gastrointestinal parasitism. This study observed seasonal patterns of gastrointestinal parasitism in cows and calves in two villages in the Central Dry Zone (CDZ), and engaged local animal health workers in an example of a routine health and production monitoring program.

Materials and Methods: Longitudinal faecal sampling of cows and calves was performed in two villages—Kyauk Aoe ('KT', 20.80°N 95.59°E) and Ya Thar ('YT', 21.63°N 95.48°E)—representative of typical CDZ cattle production systems. The CDZ has a semi-arid tropical climate, with a long-term annual average rainfall of approximately 1000 mm that falls mainly between June and October, inclusive. November to January are cooler months of the year, with average daily temperatures rising to above 40°C in April prior to the onset of the monsoon in June.

Faecal samples were collected in September and December 2014, and January, March, July and October 2015, each time from approximately 30 cows (≥ 2 years old) and 20 calves (< 1 year old). These animals were randomly selected on each sampling occasion from 200–300 animals in each village enrolled in a larger study recording bi-monthly bodyweight and reproduction. Research project team members and community animal health workers recorded observations of animal health from ten broad syndromic categories, such as diarrhoea, lameness and mortality, each month.

Faecal samples were mixed with 3% formalin, equal to approximately 20% of the faecal sample volume, before transport to a government laboratory. Quantitative faecal flotation using the McMaster method was used to identify strongyle, ascarid and cestode eggs plus oocysts, and faecal sedimentation was performed to identify trematode eggs. Strongyle worm egg counts (WEC) were log-transformed and compared between months within villages using Student's t-test.

Results: Strongyle eggs and oocysts occurred at all sampling times. Trematode eggs occurred at all times except January (YT) and March (KA and YT). However, they were generally in $\leq 10\%$ of cow samples, except in YT in October (end of the rainy season) when 30% of cows were positive. Cestodes eggs occurred infrequently in low numbers.

Strongyle WECs were the most clinically important findings. Average cow WEC varied throughout the year but was similar in both villages within sampling months ($P \geq 0.09$). WEC was least in both villages in January in the early dry season (66 ± 25 (SEM) and 40 ± 14 eggs per gram (epg) in KA and YT, respectively). In KA, WEC in other months was significantly greater than in January (range 75–135 epg; $P \leq 0.045$). By contrast, in YT only March differed significantly from January (63 ± 12 epg; $P = 0.02$); WECs in other months were similar (range 41–87 epg; $P = 0.07$ – 0.99). Overall, 27–73% of cows had positive WECs at any sampling time. The top 25% of individual WECs were ≥ 100 epg at all times, except September–January in YT (75th percentiles of 88, 50 and 50 epg, respectively). Two preliminary larval cultures suggested the main species present were *Cooperia* and *Trichostrongylus*.

Average calf WEC and seasonal pattern were similar to cows, with average WEC lowest in January. However, fewer calves were sampled and there were fewer statistically significant differences between months, compared to cows.

Syndromic health records were generally inadequate although, anecdotally, signs that could be associated with gastrointestinal parasitism, such as diarrhoea, occurred infrequently.

Conclusions: This preliminary study's most striking finding was the relatively high strongyle WECs, despite the few signs of gastrointestinal parasitism. In cattle generally, nematode burdens with WECs less than those seen here may reduce growth rates or body condition scores. Thus, parasitism may be contributing to poor calf growth rates and/or cow condition scores, widely observed problems in the CDZ. Managing parasitism may help improve growth or cow reproductive efficiency, through improved condition score, and hence farmer incomes. However, more research is needed to identify efficient parasite management strategies and the size of treatment effects.

Parasitology

P04-004-078

Comparison between cPCR and qPCR for *Trypanosoma vivax* detection in cattle

Otavio L. Fidelis Junior ¹ Paulo H. Sampaio ¹ Kayo J. G. A. Castilho Neto ¹ Rosangela Z. Machado ¹ Marcos R. Andre ¹ Luiz C. Marques ¹ Fabiano A. Cadioli ²

¹Faculdade Ciências Agrárias Veterinárias - Univ Estadual Paulista, Jaboticabal, ²Faculdade Medicina Veterinária - Univ Estadual Paulista, Aracatuba, Brazil

Objectives: *Trypanosoma vivax* is a hemoprotozoan that infects a wide range of ungulates, both wild and domestic animals and causes significant economic losses in cattle herds in tropical regions of Africa and Central and South Americas. The disease diagnosis is complicated by nonspecific symptoms such as anemia, abortion, diarrhea and weight loss. In this paper we compare the cPCR and qPCR for *T. vivax* DNA detection in three experimentally infected cattle (E1 to E3) with 2.0 x 10⁷ trypomastigotes of *T. vivax*.

Materials and Methods: Three milliliters of whole blood was collected in 10% EDTA solution on -7, 0, 1, 7, 14, 21, 28, 35, 42, 49, 56, 63, 70, 77, 84, 91, 98, 105, 112 and 120 days after infection (DAI). The DNA extraction was performed with the QIAamp DNAeasy Kit (Qiagen®), according to the manufacturer's recommendations. The extracted DNA was stored at -20°C until the moment of the use. cPCR was performed using a set of primers from the DNA sequence of the gene encoding for the cathepsin L-like enzyme (CatL) of *T. vivax* that had been described previously by Cortez et al. (2009). qPCR was performed using a set of primers from the DNA sequence of the gene encoding for the internal transcribed spacer 1 (ITS1) of *Trypanosoma* sp. and a specific probe for *T. vivax* that had been described previously by Silbermayr et al. (2013).

Results: Both techniques were able to detect the parasite DNA on 1 DAI. cPCR was able to detect 58.93% (33/56) of positive samples, detecting *T. vivax* DNA at 1, 7, 14, 21, 28, 35, 42, 49, 56, 63, 77 and 84 DAI for E1 bovine; at 1, 7, 14, 21, 28, 35, 42, 49, 56 and 63 DAI for E2 bovine; and at 1, 7, 14, 21, 28, 35, 42, 49, 56, 70 and 91 DAI for E3 bovine. Already the qPCR was able to detect 57.14% (32/56) of positive samples, detecting the parasite's DNA at 1, 7, 14, 21, 28, 35, 42, 49, 63, 77 and 84 DAI for E1 bovine; at 1, 7, 14, 21, 28, 35, 42, 49,

56 and 63 DAI for E2 bovine; and at 1, 7, 14, 21, 28, 35, 42, 56, 63, 70 and 91 DAI for E3 bovine. Furthermore Kappa coefficient was calculated between the two techniques, obtaining a value of 0.90, indicating an almost perfect agreement.

Conclusions: The use of qPCR for *T. vivax* detection is a recent technique and the results showed to be a useful tool for early diagnosis of trypanosomiasis. It is noteworthy the advantage of perform the absolute quantitation of parasitemia, obtaining the number of copies of the target gene.

Comments: We thank the São Paulo Research Foundation (FAPESP) for financial support - Process number - 2014/10572-4.

P04-004-079

Comparison Of Syringeability Of 3 Different Injectable Endectocides (Eprinomectin 20Mg/ML, Doramectin 10Mg/ML, Ivermectin 10Mg/ML)

Sandrine Lacoste ¹ Juan Munoz- Bielsa ¹ Stephane Trotebas ¹

¹Ceva Animal Health, 33500 Libourne, France

Objectives: Compliance in the use of an injectable product relies on different factors being one of them the syringeability. High fluidity allows fast injection which mitigates the risk of insufficient volume administration, needle breakage, spillage of product or injury of the user.

The aim of this study is to compare the ease of injection of 3 commercial endectocide injectables from the point of view of assessing their syringeability.

Materials and Methods: Three commercial endectocide injectables have been used in this trial: "Ivomec®" (Merial, Ivermectine 10 mg/ml), "Dectomax®" (Zoetis, Doramectine 10 mg/ml) and "Eprecis®" (Ceva, Eprinomectine 20 mg/ml). A volume of 15 ml of the tested product is withdrawn in a 20 ml glass syringe set up with a 1,2 mm or 0,8 mm diameter steel needles. A mass of 1 kg (equivalent to 1 Newton force) is applied on the piston and the time needed to empty the last 10 ml of solution is recorded.

This method is repeated 6 times for each solution at ambient temperature (20°C). Results provided are the average +/- standard deviation and statistical analysis.

Results: For the 1,2 needle, the times needed to empty the syringe were: "Ivomec®" (Merial, Ivermectine 10 mg/ml): 16,83 seconds +/- 0,75, "Dectomax®" (Zoetis, Doramectine 10 mg/ml): 22,83 seconds +/- 0,75, "Eprecis®" (Ceva, Eprinomectine 20 mg/ml): 12,2 seconds +/- 0,9. All these differences are significant (p > 0,05).

For the 0,8 needle, the times needed to empty the syringe were: "Ivomec®" (Merial, Ivermectine 10 mg/ml): 81,17 seconds +/- 3,76, "Dectomax®" (Zoetis, Doramectine 10 mg/ml): 115,83 seconds +/- 1,72, "Eprecis®" (Ceva, Eprinomectine 20 mg/ml): 52,7 seconds +/- 0,75. All these differences are significant (p > 0,05).

Conclusions: Good syringeability is important to facilitate the use of injectable products in the field and to ensure compliance. "Eprecis®" (Ceva, Eprinomectine 20 mg/ml) was demonstrated to have a significant better syringeability than the other two products tested with the two different needles tested. The superior performance can be explained by the active ingredient and the different excipients used in their formulation. This high fluidity strongly increases the comfort and convenience of use in the field.

Parasitology

P04-004-080

Use of thermographic images to detect external parasite load in cattlePaulo R. Dall' Cortivo¹Eduardo A. Dias¹Julio Otávio J. Barcellos¹Vanessa Peripolli²Concepta McManus²¹Animal Science, Federal University of Rio Grande do Sul, Porto Alegre, ²University of Brasília, Brasília, Brazil

Objectives: The aim of this study was to compare standard visual methods with infrared thermography combined with image analysis for automatic counting of ectoparasites (ticks and horn flies) in cattle under pasture conditions in Rio Grande do Sul state, southern Brazil.

Materials and Methods: Twenty Holstein cows, 10 Devon cows and 10 Braford bulls were used. Ectoparasites (ticks: *Boophilus microplus* and horn flies: *Haematobia irritans*) were counted visually and the animals were then photographed using an infrared camera (FLIR@ T300). This camera took simultaneous digital and infrared photographs so the accuracy of visual and thermographic methods were compared. A 1 cm metal object was placed on the side of the animal as a size reference. Photographs were taken from each animal at regions where the greatest number of ectoparasites were observed such as scrotum, flank, shoulder, face and perineum regions. The method used for counting ticks was based on the count of engorged females sized between 4.5 and 8.0 mm long by palpation on one side of the animal and the value was extrapolated to the other side of multiplying by two. For counting horn flies the methodology employed was visual counting one side of the animal and multiplied by two to obtain the total value. Three thermographic images and visual counts were obtained per animal. Images were first analyzed using standard Quick report® tools. This program also was used to alter the color palette from "rainbow" (camera default) to "inverted grey" to improve the image definition for counting parasites and then the program ImageJ® was used to automatically count the external parasites. Correlations between thermographic images and visual counts were calculated.

Results: Ectoparasites were cooler than the body of the animals in the thermographic images and therefore were easily highlighted by Quick report® program. In the case of ticks, they were especially visible when gravid female ticks were engorged. When small, they were frequently hidden under the animal hair, but in other regions, such as the face, they were easily seen. Horn flies stood out perfectly on thermographic images and were seen down to 3 mm in length. The correlation between visual and thermographic counts was 0.82 and increased to 0.90 when ImageJ® was adjusted to remove small dirt particles. Repeatability of measurements on the same animal was 0.87. No significant differences were seen between breeds of cattle for the ability to count horn flies using this method.

Conclusions: The use of thermographic images coupled with a software that contrasted points in the images was a useful tool and more accurate than the standard visual methods for counting external ectoparasites in cattle.

P04-004-081

Strategic Rhipicephalus microplus control through fluzuron associations reduces environmental and animal infestationIuri Vladimir Pioly Marmitt¹Samuel R. Félix¹Fabiane Niedermeyer¹Artur G. Nunes¹Bruno C. Chagas¹Elio Moro²Rogério Gama²Fernando Braga²Sergio S. D. Silva¹¹LADOPAR, Federal University of Pelotas, Pelotas, ²Zoetis Brasil, São Paulo, Brazil

Objectives: The aim of this study was to assess the parasite control program proposed by Zoetis™, comprised of an association of benzoylphenyl ureas (fluzuron) and systemic macrocyclic lactones (ivermectin doramectin) or (milbemycin moxidectin), against the tick *Rhipicephalus microplus*, compared to the lone, traditional tactical interventions of topical organophosphates and synthetic pyrethroids (Cipermetrin and Clorpirifos). Furthermore, we assess the reduction in environmental infestation; cattle infestation; and the number of tactical interventions throughout the year.

Materials and Methods: The present study was conducted in Piratini (31 °S), Rio Grande do Sul state, Brazil; from November 2013 to October 2014. Cattle included were 13 month old females, weighing 265Kg (±19Kg), all of Angus breed. These heifers were maintained under the same conditions, in a region of high environmental concentrations of *R. microplus*. Seventy eight heifers were randomized according to tick counts and live weight, and assigned to one of three treatment groups (N=26 per group). These groups were further split in two (n=13), and assigned to six independent pasture areas, to account for field variation. The groups were treated with either a combination of topical Fluzuron and subcutaneous Moxidectin (FLU+MOX); or Topical Fluzuron and subcutaneous Doramectin (FLU+DOR); and an untreated control group. Groups FLU+MOX and FLU+DOR were treated according to the manufacturer's instructions. Every 14 days the cattle were submitted to a tick count of the entire left side of the body. Whenever the mean count for a group was over 30 ticks/heifer, that group was pulverized with Cipermetrin and Clorpirifos (as instructed), called as tactical intervention. The environmental infestation was assessed through the total number of ticks counted in each group after the Fluzuron residual effect had expired (day 185). Likewise, individual animal infestation was considered every 14 days, and a mean was generated for each group. The third parameter considered was the number of tactical interventions necessary, for each group, throughout the year. Data were compared using Statistix 9.0 or EpiInfo 7.

Results: Environmental infestation was regarded as the tick count after the residual Fluzuron effect (day 185). Mean Tick counts per animal for the period from day 185 to day 364 were, for group FLU+MOX = 137.6 (±42.1); FLU+DOR = 196.2 (±61.6); and Control = 218.7 (±92.6). The pastures where the animals treated with FLU+MOX were kept were statistically less infested, when compared to the other groups (p<0.01), the other groups did not differ among themselves (Kruskall-Wallis test). Two different parameters were considered to assess animal infestation: Mean tick count per animal throughout the year; and best performance in each individual assessment. Group FLU+MOX had the lowest overall mean tick count, at an average of 8.7 ticks/animal/assessment (p<0.01). Group FLU+DOR had a count of 13.6, which was a performance better than the control, at 40.6 (p<0.01) (Tukey test). Furthermore, animals in group FLU+MOX had a statistically lower (p<0.01) tick count on 16 (of 28) assessments, compared to the control, and 10 times was it better than the FLU+DOR group. Conversely, FLU+DOR had lower counts (p<0.01) on 17 and 5 occasions when compared to the Control and FLU+MOX, respectively (Tukey test). The number of tactical interventions necessary

was greatly reduced in the Fluzuron treated groups, using FLU+MOX requiring two interventions and FLU+DOR requiring eight, while the control had 16. In this analysis FLU+MOX performed better than the control, representing a protection factor (OR=0.093, 0.02-0.43) ($p<0.01$).

Conclusions: Topical Fluzuron based treatments promote a sharp reduction in the environmental infestation of *R. microplus*; nonetheless, in the period assessed, they are not able to fully eliminate the tick from the environment. The association of Fluzuron and Moxidectin is the most efficient for environmental tick control. This association is also more efficient in reducing tick populations on the animal. Both Fluzuron based treatments outperform the control group in all parameters. Furthermore, the association of topical Fluzuron and Moxidectin reduces the need for tactical interventions, when compared to the control (OR 0.093).

P04-004-082

Prevalence of paramphistomosis in cattle slaughtered at São Miguel Island abattoir, Azores, Portugal

Carlos Pinto¹·Andreia C. Medeiros¹·Ricardo B. Barbosa¹

¹Serviço Desenvolvimento Agrário São Miguel, Portugal, Ponta Delgada, Portugal

Objectives: The aim of this work was to calculate the rumen fluke prevalence at slaughtered cattle, the geographical distribution of these parasites by herd and county in order to identify the most affected areas of SMI and investigate if *Paramphistomum* sp. and *Fasciola hepatica* share the same intermediate host, *Lymnaea truncatula*.

Materials and Methods: São Miguel Island (SMI) is the largest of the nine islands that composed the Azores archipelago, which is located in the North Atlantic Ocean (36 to 39°N, 25 to 31°W). The climate is oceanic, with 900 to 3000 mm of rain annually, and mild (17°C, range 9 to 26°C), with small temperature differences between summer and winter, and no frosts below 600 m altitude. There are about 108,000 cattle on SMI of which 52,000 are dairy cows, almost all being of Holstein-Friesians. There are 1400 dairy herds with an average of 37 cows per farm. It was possible, during meat inspection at the sole SMIA, to identify the presence of *Paramphistomum* adult forms in the rumen mucosa of 608 cattle of a total of 54144 bovines slaughtered from April 2014 to September 2015 (18 months). The geographical distribution was based on the bovine identification ear tag and two databases sources: National System of Identification and Animal Record (SNIRA) and the Information System of Agricultural Farms of the Azores (SIARA). The output cartograms were developed using Geographic Information System (GIS) and ArcGIS Desktop-ArcMAP softwares.

Results: Rumen fluke was unknown in cattle reared at the Azores archipelago until April 2014. At this time adult forms of parasite were recognized in the ruminal mucosa for the first time at SMI abattoir. Of the 608 diagnosed cases, 542 were seen in females (89.1%) and 66 males (10.85%). The prevalence of rumen flukes on cattle slaughtered population on SMIA was 1.12% being 2.77% in females and 0.19% in males. Most of rumen flukes cases were observed in females from three to nine years old and from six months to two years old in males. It was also noted that prevalence has seasonal variations, reaching high levels on summer months. The counties with the highest prevalence rates were those located in the eastern half of SMI and more than 30% of dairy herds located in these areas are affected by rumen fluke.

The geographical distribution of rumen flukes and liver flukes cases indicates that these parasites can share the same intermediate host, *Lymnaea truncatula*, at the eastern side of the Island. However, there are more cases of rumen fluke than liver fluke on the western half of SMI, where *Lymnaea truncatula* was never identified. This fact implies that exist another intermediate hosts, not yet identified, for rumen fluke. Females are more affected than males because they live more years and spend more time grazing. Most of males are reared in feedlots and are slaughtered before two years old.

Conclusions: In spite of low prevalence of rumen fluke on SMI cattle population, farmers and veterinarians should be aware of this disease, especially in areas where fasciolosis is more prevalent. The weather conditions, grazing on waterlogged pastures and areas prone to flooding, and lack of deworming practices appropriate for rumen flukes are significant risks factors for the development and spread of rumen flukes in SMI cattle.

First Report of Paramphistomum Leydeni in Irish Sheep Flocks

Ana Maria Martinez Ibeas¹·Maria Munita-Corbalan¹·Noel Byrne¹·Riona G. Sayers¹

¹TEAGASC, Fermoy, Co. Cork, Ireland

Objectives: Paramphistomosis is an important parasitic disease of ruminants caused by different species of Paramphistomidae family, which can result in decreased production and even death. Previous studies suggested that *Calicophoron daubneyi* is the predominant species affecting cattle in Europe, including Ireland. Data are limited, however. Increasing our knowledge of trematode species is essential for epidemiological surveys, as different species may have different host ranges, variable pathogenicity and anthelmintic resistance. The aim of this study was to characterise the species of rumen fluke in Irish sheep flocks using isolated eggs.

Materials and Methods: A subset of 14 Irish sheep flocks recruited to a rumen fluke prevalence study was identified for further investigation. These commercial farms recorded the highest faecal egg counts of over 250 flocks examined. Each of the 14 farmers submitted 20 catch samples from mature ewes in February 2015. These samples were subsequently pooled into four composite samples, each composite representing five individual samples. Samples were concentrated by sedimentation with eggs subsequently washed in distilled water. Rumen fluke eggs were individually collected under stereomicroscope using a modified Pasteur pipette. Samples were subjected to 3 freeze-thaw cycles at -80°C for 30 minutes followed by boiling at 100°C for 10 minutes. DNA was extracted from eggs using the QIAamp® DNA stool mini kit (Qiagen, Hilden, Germany) and quantified spectrophotometrically at 260nm. DNA samples were stored at -80°C until further analysis.

Species identification was completed by molecular analysis of 54 individually frozen eggs randomly selected from 14 different farms. The ITS-2 nuclear region was amplified by PCR using the following primers; forward 5-TGCATACTGCTTTGAACATCG-3 and reverse: 5-GTTCAGCGGGTATTACGTC-3. Amplified products were separated electrophoretically in an agarose gel and purified using a Qiaquick Gel extraction kit (Qiagen, Hilden, Germany). Purified products were forward and reverse sequenced by the Sanger method

using the same PCR primers. Sequences were compared to those available in GenbankTM, using the BLASTn (NCBI) algorithm for specific identification.

Results: The average concentration of DNA isolated from an individual egg was 3.5ng/μl (range 1.1-12.3ng/μl). The PCR technique allowed the identification of eggs individually isolated from faecal samples. All amplified PCR products were approximately 400bp in size.

All samples sequenced contained the complete ITS-2 region plus flanking 5.8S rRNA and 28S rRNA partial sequences. Of the 54 samples analysed, 52 (96.29%) were identified as *C. daubneyi*. All had identical sequences and showed 100% homology with region ITS-2 of *C. daubneyi* (GenBank accession no. KP201674.1). The remaining two samples were identified as *Paramphistomum leydeyni*. The primers used produced a fragment of 402 pb which showed 100% homology to previously published sequences of the ITS-2 region of *P. leydeni* from northern Uruguay (GenBank accession no. KJ995529.1, gb|KJ995526.1, KJ995527.1) and Argentina (GenBank accession no. HM209064.1). All *P. leydeni* sequences were identical and displayed no intraspecific variation.

Conclusions: This study constitutes the first report of *P. leydeni* infecting sheep in Ireland. The implication of this unexpected outcome remains unclear, however. Further studies are required to elucidate if this is an incidental finding of no clinical significance, or whether both *P. leydeni* and *C. daubneyi* are fluke species common in Irish flocks.

Dynamic anaplasmosis in dairy calves in intensive farming system

Letícia C. Vespasiano^{1,*}, Júlia Angélica G. Silveira², Filipe Lucas M. Mendonça¹, Elias Jorge Facury Filho¹

¹Clinical and surgery veterinary, ²Veterinary Parasitology, Federal University of Minas Gerais, Belo Horizonte, Brazil

Objectives: The Complex Bovine Parasitic Sadness annually causes great economic losses, anaplasmosis is the main pathology responsible for these losses. The aim of this study was to evaluate the dynamics of anti-*Anaplasma marginale* antibodies in different age groups cattle.

Materials and Methods: This study was conducted in a specialized intensive dairy farm. The blood of 221 Holstein animals divided into seven groups was collected by puncturing the jugular vein, 42 younger calves in the suckler group, 31 older calves in the suckler group, 27 post-weaning, 31 calves risk group, 30 calves at the stage where they get sick, 30 animals in the stable group and 30 cows in the pre-partum period. Indirect fluorescent antibody test was performed using the serum obtained to detect anti-*Anaplasma marginale* antibodies.

Results: On evaluation in epifluorescein microscope, in the objective lens of 20X and 40X increase, in indirect fluorescent antibody test for *Anaplasma marginale* in dilution 1:40 were detected 72 % in younger calves in the suckler group, 58 % in older calves in suckler group, 59 % in the post-weaning group, 39 % in the risk animals group, 27 % in the group of sick animals, 83 % in the stable animals group and 86 % in the group of pre-partum cows.

Samples were considered negative when they have not fluorescence in dilution 1:40.

Conclusions: The study demonstrates the dynamics of anti-*Anaplasma*

marginale antibodies and contain the newborn animals still passive immunity via colostrum received and the age increase these antibodies are decreasing reaching the window period. The risk groups and sick, antibodies are very low, further increasing the stable animals group, thus indicating the formation of active immunity.

P04-004-085

Survey of endoparasites and their control on goat farms in Ireland

Theo De Waal^{1,*}, Cian Codon², Laura Rinaldi³

¹School of Veterinary Medicine, University College Dublin, Dublin, ²Teagasc, Kells, Ireland, ³Department of Veterinary Medicine and Animal Productions, University of Naples Federico II, Naples, Italy

Objectives: The Irish goat industry is quite small – only about 1,014 goat keepers with a total of 15,638 goats (December 2014 census). Parasite and parasite control therefore receive very little attention within this sector. As with all grazing ruminant, gastrointestinal nematodes (GIN) remain one of the main constraints to production. The purpose of this study was to examine worm control practices and use of antiparasitic drugs in goats. A second aim was also to determine the main nematode parasite groups infecting Irish goats.

Materials and Methods: A short questionnaire survey with standard questions relating to the characteristics of the farm, the management of goats, the worm control practices and the anthelmintics used were distributed to goat farmers. Farmers were requested to complete the survey and submit faecal samples from 15 adult (> 12 months) and 5 juvenile (4-12 months) goats for analysis. Faecal worm egg counts (FEC) were performed on pooled faecal samples (5 animals per group) using the FLOTAC technique having an analytic sensitivity of 6 eggs per gram of faeces (epg).

Results: Questionnaires were sent to 64 goat farmers and 11 (17%) returned completed questionnaires with faecal samples. The majority of respondents (n=6; 55%) indicated that the main farming enterprise was dairy/cheese production. Not surprisingly, on 45% of farms, goats were kept indoors all the time. Anthelmintics were used on 72% (n=8) of farms but on the majority of farms no predetermined drenching programme were followed. Only 50% of farms used average weight of the group to determine the anthelmintic dose, which in the majority of cases (n=6) was 1.25-2x the recommended sheep dose. Overall 91% (n=10) of the farms were positive for strongyle eggs with a range of 24-1050 epg. All farms sampled (n=11) were positive for coccidial oocysts (range = 12-6480 oocysts per gram). Only 1 farm was positive for *Fasciola hepatica* and 3 farms for rumen fluke -eggs (range 18-264 epg).

Conclusions: These results indicate that exposure to nematodes and coccidia is high in Irish goat farms despite the fact that 45% of the goats are kept indoors all the time. Furthermore there is a high risk of under-dosing of anthelmintic drugs due to inaccurate weight calculation to determine the amount of drug to use. Thus the danger for the development of anthelmintic resistance exists and needs further investigation and farmers need more information on appropriate parasite control practices.

Paratuberculosis

P04-004-086

Post-mortem evaluation of fourteen adult cattle with suspected Johne’s disease based on herd disease status and/or suggestive clinical signs

Louise Britton ¹Conor McAloon ¹Aideen Kennedy ²Riona Sayers ²Joseph Cassidy ¹Jim O’Donovan ³Nola Leonard ¹Stephen V. Gordon ¹Bryan Markey ¹

¹School of Veterinary Medicine, University College Dublin, Dublin,
²Animal and Grassland Research and Innovation Centre, Teagasc,
³Department of Agriculture, Food and the Marine , Regional Veterinary Laboratory, Cork, Ireland

Objectives: Johne’s disease is caused by infection with Mycobacterium avium subspecies paratuberculosis (MAP) and leads to a chronic wasting condition in adult cattle. The immune response to MAP infection is not fully understood, which limits the performance of currently available diagnostic tests. Only a small proportion of MAP-infected cattle are thought to become clinically affected and factors which may predispose to the advancement of clinical signs remain unknown. Post-mortem investigation of naturally infected animals informs both individual diagnosis and on-farm management policies.

Materials and Methods: Between 2013-2015, fourteen adult cattle (thirteen dairy animals [nine Holstein-Friesians, two Jerseys and two Holstein-Friesian/Jerseys] and one beef bull [Simmental]) with suspected MAP infection presented to University College Dublin (UCD) for post-mortem evaluation. The cattle came from six different herds, five of which had a history of Johne’s disease. Some of the animals had been screened for MAP using various tests; six had evidence of MAP antibodies in serum or milk samples, four were MAP faecal culture positive and three were MAP faecal PCR positive. Nine animals had developed clinical signs consistent with MAP infection. The cattle were euthanized and underwent immediate post-mortem examination. Tissue samples from the ileocaecal valve and ileocaecal lymph node of all animals were processed for histopathology and stained using both haematoxylin and eosin (H&E) and the Ziehl Neelsen (ZN) method. Faecal samples from all animals were cultured for MAP (TREK ESP® para-JEM® system).

Results: Seven cattle were diagnosed with clinical Johne’s disease based on the presence of characteristic gross pathological and histopathological lesions within the ileum and MAP faecal culture results; five of these also showed evidence of moderate to severe abomasal damage caused by the parasite *Ostertagia ostertagi*. The gross and histopathological lesions within the ileum of another animal were highly unusual; although the positive faecal culture result indicated that the animal was probably MAP infected, an underlying neoplastic or immune-mediated cause of the lesions could not be discounted. This animal also had evidence of severe Type II ostertagiasis within the abomasum. One animal was diagnosed with lymphocytic-plasmacytic enteritis. Two animals were diagnosed with traumatic reticulo-peritonitis (‘hardware disease’), one of which had evidence of mild Type II ostertagiasis within the abomasum. No diagnosis could be reached for three animals.

Conclusions: These case reports illustrate that the ante-mortem diagnosis of Johne’s disease in cattle remains challenging. Clinical signs caused by MAP are relatively non-specific and may be due to other disease states; it remains important to consider all differential diagnoses. MAP may exist on farms concurrently with other herd health problems that require management; further study is necessary to elucidate potential connections between MAP and other factors, such as parasitism. Ultimately, there is an urgent requirement for the development of improved diagnostic tests for the identification of MAP infection in cattle.

Paratuberculosis

P04-004-087

Comparison of Johne’s disease prevalence on organic and conventional dairy farms in Pennsylvania.

Marie-Eve Fecteau ¹Terry L. Fyock ¹Helen W. Aceto ¹Hubert Karremann ²Raymond W. Sweeney ¹

¹Clinical Studies-New Bolton Center, University of Pennsylvania, School of Veterinary Medicine, Kennett Square, ²Rodale Institute, Kutztown, United States

Objectives: To determine is Johne’s disease (JD) prevalence on Pennsylvania (PA) organic dairy farms is different than that of conventional dairy farms. To identify differences in management practices between organic and conventional farms. To identify risk factors associated with a high prevalence of JD on organic farms, compared with organic farms that have low prevalence, and to make similar comparisons for conventional farms.

Materials and Methods: Fifty PA dairy farms (26 certified organic, 24 conventional) were enrolled. Individual milk samples were collected as part of the monthly somatic cell count testing. Milk was tested for Mycobacterium avium subsp. paratuberculosis (MAP) antibodies using a commercially available ELISA kit. Information regarding pertinent management practices was gathered during a farm visit conducted by a single trained observer. Basic statistics were used for farm demographics. Overall herd prevalence and within-herd prevalence were compared between groups. Multivariate analysis was employed to look for risk factors and associations.

Results: A total of 2,739 cows were included in the study. Organic herds had a median of 39 lactating cows (range, 20-211 cows); while conventional herds had a median of 58 lactating cows (range, 20-114 cows). Total herd size was significantly higher in the conventional group (median, 128 heads of cow) versus organic group (median, 78 heads) (p=0.018). Average daily milk production was significantly higher in the conventional group (mean, 71 lbs/day) versus the organic group (mean, 49 lbs/day)(p=0.051).

Between-herd prevalence was not statistically different between herd types with 13/26 (50%) positive organic herds versus 14/24 (58%) positive conventional herd. Among positive herds, the proportion of JD positive cows tended to be higher (yet, not statistically significant) in organic herds (2.3%) than in conventional herds (1.6%).

Risk factors associated with increased prevalence on organic farms included sharing of pasture and water source between replacement stock and adult cattle, the lack of use of bedding in replacement stock, and the lack of routine vaccination. Risk factors associated with increased prevalence on conventional farms included purchasing of animals, sharing of pasture or water source between replacement stock and adult cattle, feeding of whole milk, and the use of group maternity pens.

Conclusions: The prevalence of JD on PA organic farms is no different than that of conventional farms matched by size. The differences in management practices between organic and conventional dairy farms do not appear to influence JD prevalence within the herds.

Paratuberculosis

P04-004-088

Circulating MiRNAs In Bovine Serum and their Potential Use as Novel Biomarkers of Early Mycobacterium avium subsp paratuberculosis Infection

Ronan G. Shaughnessy ^{1*} Damien Farrell ¹ Karel Riepema ² Louise Britton ¹ David E. MacHugh ³ Bryan Markey ¹ Douwe Bakker ² Stephen V. Gordon ¹

¹School of Veterinary Medicine, University College Dublin, Dublin, Ireland, ²Department of Bacteriology and TSEs, Central Veterinary Institute of Wageningen University, Lelystad, Netherlands, ³School of Agriculture and Food Science, University College Dublin, Dublin, Ireland

Objectives: Johne's disease is a chronic enteritis of ruminants caused by *Mycobacterium avium* subspecies paratuberculosis (MAP). New disease control tools are needed as current strategies are hampered by the lack of sensitive and specific diagnostic modalities. Circulating microRNAs (miRNAs) have been shown to have potential as novel biomarkers for various human diseases, but their potential application in the veterinary sphere has not been explored. The aim of this study was to use RNA-sequencing to assess the potential of miRNAs as biomarkers for JD disease progression.

Materials and Methods: Sera from a six month experimental infection conducted at UCD consisting of MAP-challenged calves (n=6) and age-matched controls (n=6) was used. We also analysed sera that had been stored at -20°C for over a decade from a four year MAP infection model performed by the Central Veterinary Institute (CVI) of Wageningen University. Cattle defined as seropositive for anti-MAP antibodies (n=5) were compared against sero-negative cattle (n=7). Comparison of UCD and CVI samples also enabled us to assess the stability of miRNA profiles in biobanked sera. The animal work was approved by the Animal Research Ethics Committee of each university and experimental procedures were performed according to appropriate animal welfare legislation.

Results: From the UCD samples, we identified 100-200 known miRNAs with multiple isomiRs and 30 novel miRNAs. Surprisingly, the small RNA profile was highly similar to that of the biobanked CVI samples. No significant differential miRNA expression was detected between MAP-infected and their age-matched controls in either experiment. In contrast, comparing pre-infection sera of young calves to the 6 month interval of each experiment revealed miR-29a, miR-92b and miR-205 increases (2-fold) that may be due to blood-cell population changes during calf maturation (P<0.001).

Conclusions: Our study has demonstrated the stability of miRNA in serum, identified a range of novel miRNA in bovine serum, and shown the utility of small RNA sequencing approaches to explore the potential of miRNA as novel biomarkers for infectious disease in cattle.

Paratuberculosis

Genetic Markers of Resistance to Johne's Disease: Their Validation and Functional Assessment

Sanjay Mallikarjunappa ¹ Sanjay Mallikarjunappa ^{1*} and N.A.Karrow, J.Chesnais and K.G.Meade

¹University of Guelph, Guelph, Canada

Objectives: Johne's disease (JD) is a bacterial disease of ruminants, caused by *Mycobacterium avium* subsp. paratuberculosis. Resistance to JD has been shown to be heritable and many candidate gene and GWAS have identified QTLs and SNPs associated with resistance or susceptibility to JD in cattle. However, validation of these markers takes precedence prior to their inclusion in genetic selection indices to breed for JD resistance. Therefore, the objective of this study is to validate previously associated genetic markers in a new resource population, and functionally characterize their biological significance in vitro using a bovine macrophage cell line.

Materials and Methods: A total of 1000 cows from Johne's positive herds will be genotyped using the Geneseek GGD panel that contains 33,000 SNPs plus additional SNPs that were previously associated with JD. Further associations with milk somatic cell score (SCS), protein and yield, as well as fertility traits will also be assessed. To validate the biological significance of SNPs in vitro, a bovine macrophage (BOMAC) cell line will be genome edited using CRISPR/cas9 to incorporate individual SNPs in genes of interest (i.e. IL10RA), previously associated with JD resistance. Functional assessment of SNPs will be determined by characterizing their BOMAC phagocytic activity and cell signalling in response to *Mycobacterium avium* subsp. paratuberculosis and other immunostimulants (i.e. MDP or PMA + ionomycin). Total RNA will be extracted from stimulated and gene-edited BOMACs over time to profile gene expression by next-generation sequencing.

Results: The resource population for the genetic association study is currently being established based on serum ELISA, fecal PCR and/or fecal culture testing. Crispr/cas9 gene editing methodology has been used to insert a SNP in the IL10RA gene (633C>A) into the BOMAC cell line and the insertion has been validated by sequencing. Infection studies to test the biological significance of these SNPs are currently underway. Other genes of interest for genome editing of BOMACs by Crispr/cas9 include TLR4, IL23R and IL12R.

Conclusions: Johne's disease is implicated with severe economic losses to dairy industry and is also attracting significant public health concern. The disease is distributed worldwide and a possible way of its control is through breeding animals for enhanced resistance. Currently there is a knowledge gap concerned with the validation of previously associated genetic markers before they could be incorporated in genetic selection. Validation and assessment of biological significance of these markers will provide evidence that could aid in their inclusion in future dairy breeding programmes.

Paratuberculosis

P04-004-090

Prevalence of Mycobacterium avium subs. paratuberculosis in Portuguese dairy herds

Elisabete Martins ^{1,2,3*} Joao Niza-Ribeiro ¹ Pedro Oliveira ¹ Eva Lemos ¹ Bruno Oliveira ⁴

¹Instituto de Ciências Biomédicas Abel Salazar, ²Instituto de Saúde Pública da Universidade do Porto (ISPUP), Oporto, ³Department of Veterinary Medicine, Escola Universitaria Vasco da Gama, Coimbra, ⁴Department of Computers Science, Faculdade de Ciências, Universidade do Porto, Oporto, Portugal

Objectives: To establish the proportion of dairy herds (members of the Portuguese Dairy Record Association ANABLE) infected by *Mycobacterium avium* subsp paratuberculosis (MAP) and its distribution at municipality level.

Materials and Methods: From the total of 1263 farms registered in ANABLE data base (ADB), 222 (DB) were classified according to MAP infection status. In these herds all cows aged over 30 months, were MAP tested by indirect biphasic ELISA. Individual results were negative (NEG), positive (POS) or dubious (DUB). Farm level of infection was defined based on all adult cows test as Negative (NEG) if all cows were negative, and Positive (POS) if otherwise. Farms from ADB were plotted in ArcGIS Vs10 at the municipality level, and proportion of infected herds was determined and represented at the same level. The sampling fraction was determined and used to correct the potential sampling bias.

Results: Our sample comprised 18% (222) of the ADB farms and 43.2% (48) municipalities (Mnc). The 48 municipalities comprise 1074 (85%) of the total 1263 farms in ADB. The global proportion of infection was 58% (CI 95%:±3). Prevalence at municipality level ranged from 0 to 100%. The proportion of positive farms was zero in 25% of the Mnc. Positive Mnc had a proportion of infected samples that ranged from 1% to <33% in 50% of the Mnc; 33% to <67% in 18.7% of the Mnc and >67% in the remaining 6,3%.

Maps representing the sampling fraction and proportion of infected farms were produced for the municipalities and districts levels. Inferences for prevalence distribution of MAP in dairy herds in Portugal are presented. Previous studies reported in 2004 49.5% of MAP herd prevalence in the north of Portugal. This is the first effort to assess the continental prevalence of MAP in the country.

Conclusions: This study supports a high global level of MAP infection in Portuguese dairy herds, but important heterogeneity at the municipality level. Compared to previous reported prevalence, this study suggests the possibility of a higher national prevalence.

Evaluation of the diagnostic value of colostrum antibody ELISA for early detection of Mycobacterium avium subsp. paratuberculosis in dairy cattle

Kristina R. Mueller¹, Richard Laven¹ and Jenny Nixey

¹IVABS, Massey University, Palmerston North 4442, New Zealand

Objectives: Early diagnosis of subclinical Mycobacterium avium subsp. paratuberculosis (MAP) infected animals is important to control and monitor paratuberculosis in dairy herds; however, there is a lack of reliable diagnostic tests for early detection of MAP.

The objectives of this study are to evaluate the performance of a commercial milk MAP antibody ELISA in first day colostrum and to compare the diagnostic value of milk MAP antibody ELISA in colostrum to that of standard serum antibody ELISA in early detection of MAP infection in cattle.

Materials and Methods: Colostrum samples were taken between 0 and 4 days-in-milk (DIM), and serum samples were collected during the spring calving period in 2015 from 377 mixed-parity cows in a MAP positive commercial Jersey dairy herd. Lactation and body weight records were obtained during the trial period to match them with results of individual animal diagnostic testing for MAP. Sample analysis is still ongoing at this point. The odds for colostrum samples testing positive in a MAP-specific Immunoglobulin G (IgG) ELISA as a function of covariates parity and

DIM will be evaluated using logistic regression. Sensitivity and specificity of the colostrum-based ELISA will be determined using serum ELISA results and information from individual cow performance as references.

Results: The apparent seroprevalence in the herd was 4.77%. The majority (78%) of seropositive animals were four years of age or older. Two seropositive animals and one animal with an equivocal test result were two years of age, indicating high levels of exposure within the herd. The average body condition score of seropositive cows was 4.44 out of 10 which was above the herd average of 4.39 out of 10. Sample and data analysis are not completed at this point; further results will be presented at the congress.

Conclusions: First day colostrum samples are easily obtained and may provide a promising alternative to serum antibody ELISA for early individual animal testing if the test sensitivity and specificity are acceptable.

Paratuberculosis

Long term survival of animals positive to MAP diagnostic tests in Ireland

Peter Mullaney¹, Kevin Kenny², Margaret Good³, John Egan⁴

¹Department of Agriculture, Kildare Street, Dublin 2, ²Central Veterinary Research Laboratory, Department of Agriculture, Fisheries and Food Laboratories Complex, Backweston Campus, Stacummy Lane, Celbridge, Co. Kildare, ³Department of Agriculture, Kildare Street, Dublin 2, ⁴Veterinary Research Laboratory, Department of Agriculture, Fisheries and Food Laboratories Complex, Backweston Campus, Stacummy Lane, Celbridge, Co. Kildare, Ireland, Ireland

Objectives: To determine longevity of animals positive on a seroprevalence survey for Mycobacterium avium paratuberculosis and of animals positive on a faecal test submitted on clinical animals to the Regional Veterinary Laboratories.

Materials and Methods:

Three groups of animals were included in the survival analysis.

1. Animals positive on the 2005 seroprevalence survey (Good et al., 2009)
2. Animals positive on a faecal test submitted on clinical animals to the Regional Veterinary Laboratories in 2005.
3. Two control animals were matched with each positive animal. These animals were picked from herds that had been tested negative on the prevalence survey and were matched on enterprise type, herd size and age of animal.

Three groups of animals were included in the survival analysis.

1. Animals positive on the 2005 seroprevalence survey (Good et al., 2009)
2. Animals positive on a faecal test submitted on clinical animals to the Regional Veterinary Laboratories in 2005.
3. Two control animals were matched with each positive animal. These animals were picked from herds that had been tested negative on the prevalence survey and were matched on enterprise type, herd size and age of animal.

Results: 201 animals were positive on the prevalence survey. 8 were still alive eight years later. Of the 192 animals that were dead, one had been exported, 13% had died on the farm and 85% were sent for slaughter. Of the 400 control animals twenty five animals were still alive 8 years later. Of the 375 animals that were dead, three had been exported, 13% had died on the farm and 85% were sent for slaughter.

Animals positive on a faecal test.20% had been sold. 20 were sent to the slaughterhouse, 18 died on the farm and one animal was exported. Animals survived from 1 to 1056 days after a positive faecal test.Of the 80 control animals 5.7% were still alive 8 years later. Of the 74 animals that were dead, one had been exported, 16% had died on the farm and 84% were sent for slaughter.

201 animals were positive on the prevalence survey. 8 were still alive eight years later. Of the 192 animals that were dead, one had been exported, 13% had died on the farm and 85% were sent for slaughter. Of the 400 control animals twenty five animals were still alive 8 years later. Of the 375 animals that were dead, three had been exported, 13% had died on the farm and 85% were sent for slaughter. Animals positive on a faecal test.20% had been sold. 20 were sent to the slaughterhouse, 18 died on the farm and one animal was exported. Animals survived from 1 to 1056 days after a positive faecal test.Of the 80 control animals 5.7% were still alive 8 years later. Of the 74 animals that were dead, one had been exported, 16% had died on the farm and 84% were sent for slaughter.

Conclusions: The survival of positive animals on the prevalence survey compared with controls shows that on average positive animals died a year sooner than controls. Of the 40 animals positive on the faecal sample, the great majority were dead within 250 days of the sample being taken whereas 5.7% of the control animals were still alive five years later.

Paratuberculosis

P04-004-095

Applying Sociology to the control and prevention of Paratuberculosis

Aine Macken-Walsh¹Conor McAloon² Lisa Moran³Anne Byrne³Michael Doherty²Paul Whyte²

¹Rural Economy Development Programme, Teagasc, Galway, ²School of Veterinary Science, UCD, Dublin, ³School of Political Science and Sociology, NUI, Galway, Galway, Ireland

Objectives: This paper presents the framework and indicative outcomes of an interdisciplinary project involving veterinarians and sociologists. Responding to the ongoing challenge of improving the uptake and effective implementation of herd health programmes at farm-level, the paper utilises social science to investigate farmer behavioural factors. The paper identifies key categories of sociological data that are directly relevant to informing a HACCP-based herd health programme for the control and prevention of bovine paratuberculosis.

Materials and Methods: We used in-depth qualitative methodologies to identify farmers' values and knowledges relevant to animal disease. The utility of such a methodological approach has been established in research that has analysed implementers' engagement with HACCP (Lowe and Taylor, 2013) and the social and cultural aspects of herd health management at farm level (Vanclay and Enticott, 2011). Qualitative methodologies, rather than eliciting interviewees' self reported data, involve the researcher uncovering values, beliefs and practices

and analysing them. In this study we used the Biographic Narrative Interpretive Method (BNIM) (Wengraf, 2001) to undertake twelve case studies that represent a wide range of farm holders (with and without a prior diagnosis of paratuberculosis). In addition, ethnographic research was undertaken, which involved observing farmers' implementation of herd health measures in practice on farms known to be currently infected with paratuberculosis. The data were transcribed and analysed using a framework of values and knowledges concepts

Results: Animal disease such as paratuberculosis, has cultural (pride), social (relationship) and economic (monetary) costs for farmers. On the other hand, optimal animal health gives rise to social, cultural and economic benefits. Thus, farmers, can be diversely motivated to implement herd health programmes. Effective promotion of these requires communicating not only the economic but also the cultural and social benefits of effective implementation (and costs of non-implementation). Furthermore, farmers' knowledge constructs (claims, lore/scripts and practices/practical consciousness) in relation to animal disease are identified. Farmers have professionally or scientifically derived information (claims) in relation to animal disease, which they believe is factual. In addition, lore and myths (scripts) can circulate within the farming community in relation to animal disease. Also, farmers have habits or pragmatic constraints (practical consciousness) that impact their management of herd health measures. We argue that in order to address barriers and exploit opportunities for successful implementation, the design of herd health measures and veterinary advice must engage with knowledge constructs (claims, scripts and practical consciousness) in a targeted way. Some knowledge constructs are obstructive to effective herd health management and thus must be challenged by policy makers and veterinary practitioners. Others are supportive to herd health and can be strategically promoted within the farming community.

Conclusions: This paper has introduced an extended suite of sociological concepts and methodologies that, to the authors' knowledge, have not been utilised in the literature on farm-level herd health heretofore. Informed by the sociology, herd health and food safety literature, our framework can be applied to inform the design of wide-ranging herd health and HACCP-based programmes. Areas for further work include broadening the research focus to include the knowledge constructs of other key stakeholders in animal health, including veterinary scientists/practitioners and policy-makers and examining the intersections between them.

Bayesian estimation of prevalence of paratuberculosis in dairy herds enrolled in a voluntary Johne's Disease Control Programme in Ireland

Conor G. McAloon¹Michael L. Doherty¹Paul Whyte¹Luke O'Grady¹Locksley L. M. Messam¹Simon More¹Margaret Good²Peter Mullaney²Sam Strain³Martin J. Green⁴

¹Section of Herd Health and Animal Husbandry, School of Veterinary Medicine, University College Dublin, ²Department of Agriculture, Food and the Marine, Dublin, Ireland, ³Animal Health and Welfare Northern Ireland, Dungannon, Co. Tyrone, ⁴School of Veterinary Medicine and Science, University of Nottingham, Sutton Bonington, United Kingdom

Objectives: Bovine paratuberculosis is a disease characterised by chronic granulomatous enteritis which manifests clinically as a protein-losing enteropathy causing diarrhoea, hypoproteinaemia, emaciation and, eventually death. Some evidence exists to suggest a possible

zoonotic link. A national voluntary Johne's Disease Control Programme was initiated by Animal Health Ireland in 2013. The objective of this study was to use Bayesian methodology to estimate herd level prevalence of paratuberculosis in Irish herds enrolled in the national voluntary JD control programme during 2013-14.

Materials and Methods: Two datasets were analysed in this prevalence study. An initial analysis utilised data that had been collected in Ireland during 2005 (including 5822 test results from 119 herds), and was used to construct model priors. Model priors were updated in a Bayesian model with data from a primary (2013-14) dataset. The primary dataset was generated as part of the Animal Health Ireland voluntary Johne's Disease Control Programme and included test records from 99101 animals across 1039 Irish dairy herds.

Results: Overall, 57% of herds in the primary dataset had at least 1 positive test result. Preliminary analyses suggest a median posterior estimate (95% credible interval) for herd prevalence of approximately 0.28 (0.23, 0.34), 10th, 20th, 75th and 90th percentiles were 0.25, 0.26, 0.30 and 0.32 respectively. Across all herds the average within herd prevalence was found to be 0.043 (0.037, 0.050). A sensitivity analysis demonstrated that the final estimate was most sensitive to the prior for the prevalence within infected herds.

Conclusions: This study represents the first use of Bayesian methodology to estimate the prevalence of paratuberculosis in Irish dairy herds. Analyses are ongoing, however, preliminary results suggest that the herd level prevalence estimate for dairy herds enrolled in the voluntary national Johne's Disease Control Programme is higher than previous Irish national estimates, but still lower than estimates from other major dairy producing countries.

Paratuberculosis

Control of *Mycobacterium avium* subspecies paratuberculosis (MAP) in an Irish context

Aideen E. Kennedy¹, Jim O'Mahony², Jim O'Donovan³, Bryan Markey⁴, Louise Britton⁴, Kevin Kenny⁵, Noel Byrne¹, Riona Sayers¹

¹Animal & Biosciences, Teagasc, Moorepark, Fermoy, Co. Cork, ²Biological Sciences, Cork Institute of Technology, Cork, ³Department of Agriculture, Food and the Marine, Regional Veterinary Laboratory, Model Farm Road, ⁴UCD School of Veterinary Medicine, University College Dublin, Belfield, Dublin 4, ⁵Department of Agriculture, Food and the Marine, Central Veterinary Research Laboratory, Backweston Campus, Co.Kildare, Ireland

Objectives: Johne's disease (JD), caused by *Mycobacterium avium* subspecies paratuberculosis (MAP), continues to present diagnostic difficulties, thereby hampering on-farm control programmes. Although the prevalence of JD has increased in Ireland, it is not a recognised clinical entity on the majority of Irish farms. The objective of the current study was to complete a longitudinal study in a MAP seropositive dairy herd to investigate the success of culling and calf management in controlling MAP in an Irish context. A secondary objective was to identify if consistent MAP ELISA positive results provided a reliable indicator of JD gross pathology.

Materials and Methods: A 139 cow dairy research herd was recruited to the study. Prior to study commencement, no clinical cases of JD had been reported in the herd. Monthly collection of blood samples for ELISA testing began in May 2012. This continued until December 2014, at

which point sampling continued on a quarterly basis. All samples were tested using the ID Screen Paratuberculosis Indirect Screening Test. Results were reported as S/P%, a positive ELISA reported at readings of greater than 70S/P%. Faecal samples from ELISA positive cows were collected weekly from September to December 2012 and tested by PCR. Faecal samples were also submitted for faecal culture on an intermittent basis. ELISA positive cows were subject to veterinary examinations throughout the testing period.

In 2013, a single cow (Cow A) was selected for pathological examination (PE) on the basis of repeatedly recording ELISA readings greater than 150S/P%. Cow A also yielded multiple positive PCR results and a single faecal culture positive result. In winter 2013 and winter 2015, a number of additional cows were selected for PE (12 in total). In 2013 the selection criteria for culling was a minimum of 6 ELISA positive results over a 12 month period. The final cow was selected based on 2 positive tests and age.

Cows which recorded at least one ELISA positive result were calved in isolation and returned to the herd post-calving. Colostrum from these cows was discarded and their calves fed colostrum from a consistently ELISA negative dam. All other calves only received colostrum from their own dam.

Results: At the first sampling in May 2012, 10 of the 139 cows tested ELISA positive. The highest number of ELISA positives recorded over the testing period was in July 2013, when 16 cows were categorised as positive. These results exclude the three month period after the statutory annual test for bovine tuberculosis. A total of 12 cows yielded greater than six ELISA positive results over the duration of the study. Veterinary examination did not detect any clinical signs of JD in these animals.

Pathological examination of Cow A revealed severe gross changes consistent with JD (July 2013). The remaining cows were chosen for culling based on consistent ELISA positive readings only. None were faecal culture positive. No cow showed gross lesions of JD on PE. Following the culling exercise, 9 cows remained in the herd which had intermittently generated ELISA positive results. Within three months of the final cull, these cows recorded negative ELISA results and remained negative along with the remainder of the herd until August 2015. A total of five cows were categorised as ELISA positive in August. A single cow (Cow B) recorded an S/P% of 254 and, as she was due for culling due to her age, and had previously tested ELISA positive in January 2014, was subjected to PE in November 2015. Clinical veterinary examination prior to culling yielded no abnormalities and no gross lesions were identified on PE. Histological test results are imminent.

Animals reared using JD management protocols are due to enter the milking herd in spring 2016.

Conclusions: Culling programmes when combined with appropriate management have the potential to reduce the herd prevalence of MAP ELISA positive results. Based on the results of this study, consistently positive MAP ELISA results are not a reliable indicator of the presence of pathological lesions associated with JD. Use of additional tests (faecal culture or PCR) is likely to increase confidence in determining cow selection for culling.

Paratuberculosis

P04-004-098

Proteomic analysis of *Mycobacterium avium* subspecies paratuberculosis in vitro and the identification of seroreactive antigens

Stephen Hyland¹, Jarlath E. Nally², Kieran E. Meade³, Stephen V. Gordon⁴

¹UCD School of Veterinary Medicine, University College Dublin, Dublin, Ireland, ²Bacterial Diseases of Livestock Research Unit, National Animal Disease Center, Agricultural Research Service, United States Department of Agriculture, Ames, United States, ³Animal & Grassland Research and Innovation Centre, Teagasc, Meath, ⁴UCD Conway Institute of Biomolecular and Biomedical Research, University College Dublin, Dublin, Ireland

Objectives: Johne's disease (JD) is a chronic infectious disease of ruminants. The control of Johne's disease is severely hampered by the lack of sensitive and specific diagnostic tests in the sub-clinical stage of the disease. The causative agent of Johne's disease is *Mycobacterium avium* subspecies paratuberculosis (MAP). We postulate that one route to new diagnostics is through the identification of novel antigens from the pathogen. We aim to achieve this through detailed proteomic analysis of MAP and using these proteins to identify novel seroreactive antigens in sera from infected cattle.

Materials and Methods: In this study, MAP CIT003 was cultured until it reached log phase of the growth cycle at which time it was harvested for analysis by 2-D Gel Electrophoresis. Immunoblot analysis was conducted using pooled serum samples from 9 infected cattle of known Johne's disease status, confirmed using multiple diagnostics. A total of 15 protein spots were identified as seroreactive antigens. Protein spots were extracted and prepared for mass spectrometry analysis using a tryptic digest. Protein identification and bioinformatics analysis was then conducted using Peaks, BLAST and Interpro software.

Results: The MAP K10 proteome was used as a reference proteome for protein identification as MAP CIT003 is at present incompletely characterised. All 15 seroreactive antigens were identified as being present in MAP K10. While some of the antigens have previously been identified as seroreactive (e.g. LprG), 7 were previously uncharacterized and annotated as hypothetical proteins. These latter protein sequences were analysed using BLAST and Interpro to determine similarities in corresponding species of other *Mycobacteria* as well as to identify potential protein functions. A novel seroreactive protein (Q740L1) was predicted to function in response to stress, while another (Q73V64) was predicted to function in metal ion binding. Results suggest potential roles for these novel seroreactive proteins in response to the immune response of the host. The analysis of the function of other identified and previously uncharacterised proteins is currently on-going.

Conclusions: Characterisation of proteins expressed by MAP have the potential to give new insights into the pathogenicity of this important causative agent of disease. Furthermore, the seroreactivity of these proteins may ultimately aid improved diagnosis of JD by means of inclusion into a novel antigen cocktail for JD detection. Confirmation of seroreactivity of identified novel proteins is currently being conducted.

Presence of *Mycobacterium Avium* Subs. Paratuberculosis Dna in Milk used to Feed Calves in Portugal

Célia Leão ¹Ana Botelho ¹Carla Aguiar ²Elisabete Martins ²Inês Rebelo ³Telmo P. Nunes ³Ricardo Bexiga ^{3,*}

¹Instituto Nacional de Investigação Agrária e Veterinária, Lisboa, ²InVivoNSA Portugal SA, Cantanhede, ³Centro de Investigação Interdisciplinar em Sanidade Animal, Faculdade de Medicina Veterinária, Universidade de Lisboa, Lisboa, Portugal

Objectives: Dairy farmers often feed waste milk to calves, milk that cannot be used for human consumption, including colostrum, high cell count milk or milk with antimicrobials from animals under treatment. *Mycobacterium avium* subsp. paratuberculosis (Map), the causal agent of paratuberculosis is transmitted more frequently through the fecal-oral route, with evidence that calves under 6 months of age are the most susceptible to infection. Rearing calves with waste milk may thus increase the risk of transmission of paratuberculosis on farm.

Materials and Methods: This study aimed at detecting the presence of Map on milk fed to calves, and to address possible risk factors for that presence. A questionnaire was performed on 37 commercial dairy farms in Portugal, and waste milk samples were collected on 3 different occasions separated by a minimum of one week. In case of farms not feeding waste milk to calves, bulk tank milk samples were collected instead. A nested real time PCR for the detection of the IS900 sequence was performed for the detection of Map.

Results: A majority of farms (89.2%) fed waste milk to calves. From the 33 farms that fed waste milk to calves, only one pasteurized the milk before feeding it to calves. Results of the IS900 nested real time PCR showed that 51.5% of the farms that were feeding waste milk to calves had a positive result for Map on that milk. None of the studied risk factors were significantly associated with the presence of Map in milk samples, however the risk of having a sample positive for Map on PCR was 3.5 times higher for farms that bought in animals from a single origin and 1.9 times higher for farms that bought from multiple farms, when compared with closed farms. Having a calving area for multiple cows also increased the risk of a positive Map result by 1.5 when compared with single pens for calving. The risk of having a positive Map result on waste milk was 1.6 times higher for farms feeding that milk to male calves and 1.4 for farms feeding to both male and female calves, when compared with farms not feeding waste milk.

Conclusions: This study highlights paratuberculosis as one of the potential risks of feeding waste milk to calves, and the need for mitigations strategies to be in place to avoid unnecessary disease transmission.

Paratuberculosis

P04-004-100

The use of web based economic Health Evaluator to increase farmer engagement with Johne's control

Peter Orpin ^{1,2,*}Richard J. Sibley ³

¹Park Vet Group, Leicester, ²Special Lecturer, Nottingham University, Nottingham, United Kingdom, ³Westridge Veterinary Group, Witheridge, Tiverton

Objectives: The economic impact of Johne's Disease (JD) is traditionally divided between direct losses (milk loss, culling) and indirect losses and associations (e.g. udder health).

However, JD costs are often expressed as an average cost across all herds, for example, £27/ cow using direct costs only which often underestimate the true impact of JD.

Higher prevalence herds however incur substantively higher costs due to consequential losses of increased JD related culling and retention of cows with low fertility and health potential. The correct estimation of JD costs using farm specific health evaluation can help improve engagement in JD control.

Materials and Methods: In 2007 a Health Evaluator was developed

within a web based Health Planning tool (www.myhealthyherd.com) allowing both the vet and farmer to enter their own targets and costs for all the key health areas (fertility, udder health, lameness, sick cows/metabolic, culling and youngstock). The program was populated with default incidence and cost targets for 29 health values and this allows for farm specific overall losses for health areas to be calculated. The economic benefit between the target for the herd and the actual performance is expressed as a "profit opportunity" which can be achieved by improving performance in that particular area.

The whole herd economic evaluation was combined with outputs from the Disease manager module that used the risk and test prevalence data to predict the estimated future true JD herd prevalence for the herd. The program allowed for an agreed economic evaluation of the estimated impact of diseases and culling losses, which is used to help motivate engagement with veterinary led control programs. The graphical outputs were used within veterinary practices and within commercial and regional control schemes in the UK to help engage over 2000 dairy farmers with effective JD risk assessments with a proportion using health evaluations to support their management plans.

Results: Analysis of 833 UK dairy herds (30,820 culls) within the myhealthyherd program revealed that 23% of all cows culled were culled due to sickness, death or casualty. Within the program the culling reasons and costs are defined and split into losses due to no value culls/deaths (£3,499), emergency culls (£2,182) and culls sold live at the end of lactation (£1,238). The proportion of the herd culled within these categories was further subdivided according to culling reason. 2915 cows were culled due to health problems with a lower, median and upper quartile incidence of 0%, 1.5% and 2.5%. The wide variation between herds clearly illustrates that poor health is not inevitable and can be controlled. The farmer may not be aware of this opportunity unless this is clearly illustrated.

In the authors experience practical on farm health evaluation typically reveals that in herds with high prevalences of Johne's disease the economic impact can be in excess of 1-3 pence per litre due to JD with these losses continuing (at a lower level) for several years before the disease is fully controlled. The economic impact is reflected in consequential losses due to fertility and wider disease issues (due to retention of cows with poor fertility and health potential due to accelerated JD culling). Typically udder health may also be jeopardised as insufficient replacements may be available with penalties for poor milk quality and escalating clinical incidence of mastitis.

Conclusions: The true impact of JD is often underestimated. To fully engage farmers with Johne's control programme a full economic health evaluation can be used to simply illustrate the profit opportunities that can be achieved through effective control. If the audit is performed using agreed targets and costs, which are specific to the farm this will produce a credible figure that the farmer is more likely to comprehend

The use of a farm specific Health Evaluator that illustrates direct, indirect and consequential losses using simple inputs with credible outputs is a useful method of motivating farmers to commit to long term JD control programs.

Paratuberculosis

The effects of subclinical *M. avium* ssp. paratuberculosis infection on the health and production parameters of dairy cows

Viktor Jurkovich ¹ Barbara Bognar ¹ Krisztian Balogh ² Maria Kovacs-

Weber ³Rubina Tunde Szabo ³Peter Kovacs ¹Laszlo Konyves ¹Kinga Fornoyos ⁴Miklos Mezes ²

¹Department of Animal Hygiene, Herd Health and Veterinary Ethology, Szent Istvan University Faculty of Veterinary Science, Budapest, ²Department of Animal Nutrition, ³Institute for Animal Breeding Science, Szent Istvan University Faculty of Agricultural and Environmental Sciences, Godollo, ⁴Vet-Controll Ltd., Budapest, Hungary

Objectives: Paratuberculosis (also called Johne's disease) is a chronic disease caused by *Mycobacterium avium* ssp. paratuberculosis (MAP). This incurable illness is clinically manifested at 3 or 4 years of age, usually after the 2nd lactation period. It occurs worldwide and it is one of the most economically important infectious diseases of ruminants.

Materials and Methods: The effect of subclinical paratuberculosis infection on the health and production parameters of cows was studied in a Hungarian dairy herd. Fifteen infected (no clinical signs, but faeces PCR positive; MAP+) and 15 healthy (faeces PCR negative; CO) dairy cows were involved in the study. The age of the cows (MAP+: 5.5±1.6, CO: 5.2±2.8 years) and the number of lactations (MAP+: 3.5±1.4, CO: 3.4±2.2) did not differ at the start of the experiment. During the study housing and feeding conditions were the same in both groups.

Blood and urine samples were taken for major biochemical parameters, from 2 weeks prepartum to 120 days postpartum (d -10-14, 2-5, 10, 20, 30, 40, 50, 60, 80, 100, 120) and production data were also collected.

Results: No statistically significant difference was observed between groups regarding blood plasma total protein, albumin, total cholesterol, triglyceride, beta-hydroxybutyrate, non-esterified fatty acid and urea concentrations, and aspartate aminotransferase and gamma-glutamyl transpeptidase activity. Urine net acid-base excretion was higher - but within the physiological range in the infected group. The body condition of infected animals was significantly worse than that of healthy ones, and there was negative correlation between body condition score (-0.53, p<0.0001), the faeces score (-0.37, p<0.0001) and the rumen fill score (-0.22, p<0.001). The milk yield tended to be lower (47.4±12.1 vs. 51.9±13.1, p=0.0632) in the infected group. Other health and reproductive parameters (number of mastitis treatments [2.8±1.3 vs. 0.5±3.2, p=0.002], number of treatments due to reproductive tract problems [6.4±4.6 vs. 2.4±1.8, p=0.0004], length of service period [169.7±70.7 vs. 84.6±33.0, p=0.0001]) were significantly worse in MAP+ cows compared to the control group. First service conception rate was considerably lower in the infected cows.

Conclusions: The subclinically infected cows are more susceptible to other diseases and the latency period of the disease is long, which urges more attention to be paid to the prevention and eradication of paratuberculosis.

Acknowledgement: The study was financially supported by the grant No. KMR_12-1-2012-0161.

P04-004-103

Associations between Johne's disease and productivity in UK dairy herds

Jessica Reynolds ¹Chris Hudson ^{1*}

¹Nottingham Vet School, Loughborough, United Kingdom

Objectives: The objective of this study was to quantify the type and magnitude of association between paratuberculosis antibody status and milk yield and fertility parameters in UK dairy cows. A large pre-existing dataset was used to explore associations between MAP antibody status and milk yield and reproductive performance. Quantification of the size of MAP productivity associations in the UK herd was extremely justifiable, given the lack of UK based research and much disparity between production loss estimates from other non-UK studies. This quantification could be further rationalised considering the obvious economic implications of the disease.

Materials and Methods: After data quality analysis; milk recording, fertility and serological data collected from a major milk quality laboratory was retained for 73 herds. Paratuberculosis status was categorised at lactation level via use of the last status per lactation. By definition, each category allocated at the last recording reflected the MAP antibody status of the individual from several preceding measurements. A continuous response multilevel linear regression model was constructed to examine the association between paratuberculosis milk ELISA status and 305 day yield. Two logistic regression models were used to evaluate the association between ELISA status and odds of pregnancy by 100 DIM and ELISA status and odds of service by 80 DIM respectively. Model assumptions and fit were tested and verified in all models.

Results: The following provisional results were derived from this initial analysis. Positive MAP status was associated with a decrease of 366 litres per 305 day lactation compared to lactations with a negative MAP status. A 25% reduction in the odds of service by 80 DIM was also found associated with this status. Furthermore, positive MAP status was associated with a 79% reduction in the odds of pregnancy by 100 DIM. Uncertain MAP status was not significantly associated with 305 day yield and provisionally positive MAP status was not significantly associated with odds of service by 80 DIM.

Conclusions: Positive MAP status clearly has a negative association with milk production in the UK dairy cow. The magnitude of this association however appears less than documented previously, thus an investigation re-evaluating this in the UK dairy herd could be justified. A very large negative association was also observed between positive MAP status and odds of pregnancy by 100 DIM. This provisionally suggests that MAP infection is negatively associated with establishment of pregnancy and to a lesser extent with oestrus expression or post-partum anoestrus. It is important however to note that producer bias may be linked to these negative associations.

Social network analysis of cattle positive for Johne's disease by faecal culture from submissions to the Regional Veterinary Laboratories in Ireland.

Cosme Sanchez-Miguel¹, James Crilly², John F. Mee³, Niamh Casey⁴

¹Cork Regional Veterinary Laboratory, Dept. of Agriculture, Food and the Marine, Cork, Ireland, ²SECID, Tirana, Albania, ³Animal and Bioscience Research Department, Teagasc, Moorepark, Co. Cork, ⁴Veterinary College, UCD, Dublin, Ireland

Objectives: National risk-based surveillance programmes for paratuberculosis (JD) can be hampered by the difficulty in networking disparate databases across organisations. This is particularly important when attempting to track the movement of *Mycobacterium avium*

subspecies paratuberculosis (MAP)-positive animals between herds. This study reports the use of social network analysis (SNA) in the epidemiology of JD. The aim of the study was to describe the network of confirmed (faecal culture) MAP-positive animals in Ireland by linking their movements through different premises.

Materials and Methods: Networks were constructed by linking a dataset of laboratory records of MAP culture-positive animals obtained by passive surveillance over an 11-year period (2005-2015) with the national Animal Identification and Movement System (AIMS) database. The dataset was exported to UCINET v.6 and Pajek32 v.3.01 and organised in an adjacency matrix consisting of a collection of nodes (premises) and an array of arcs (directed movements) linking the nodes (network). Movements to a factory or knackery were excluded and, due to the epidemiology of JD, a movement through a mart from premises A to B was represented as a movement from A to B. The nodes were categorised (attributes) and graphed in an arbitrary space for visual assessment. Networks represent patterns of connectivity of populations and describe aspects of disease transmission. The centrality value (a structural attribute that represents the node's importance within the network) was calculated for each node to determine its relative potential for MAP spread.

Results: In total there were 1062 confirmed (faecal culture) MAP-positive animals with a total of 898 movements. The network was organised in an adjacency matrix consisting of a collection of nodes (n=990 premises; 489 MAP-positive, 501 MAP-unknown status) and an array of directed movements or arcs (n=658) linking the nodes. The network was fragmented into 219 components (sub-networks where nodes are connected within but do not have ties with other sub-networks) ranging from 1 to 81 nodes; 64 (29%) components had two or more MAP-positive herds (nodes) linked by movement of MAP-positive animals. MAP-positive animals were moved once (56.9%), twice (24.4%), thrice (9.8%) or more times (8.9%) between nodes.

Conclusions: Social network analysis (SNA) is a formal methodology for the analysis and illustration of the relationship between movements of animals and transmission of contagious pathogens associated with those movements. This study addresses the relationship between animal movements and disease detection. It identified connectivity between those premises most likely to facilitate the transmission of MAP via animal movements which was not apparent from either the laboratory records or AIMS databases. Thus SNA provides a novel approach to the development of risk-based surveillance for MAP and potentially for other veterinary disease prevention programs.

Strategic options for the management of Johne's Disease in UK dairy herds

Richard Sibley¹, Peter Orpin²

¹West Ridge Veterinary Practice, Witheridge, ²Park Vet Group, Leicester, United Kingdom

Objectives: This paper will demonstrate the variety of strategic options used by dairy farmers throughout the United Kingdom for the prevention and control of Johne's Disease in dairy herds, and explain how the most appropriate option can be selected and then tailored to the needs and aspirations of the farmer.

Materials and Methods: Management programmes for the prevention and control of Johne's Disease in dairy herds have been initiated in parts

of the United Kingdom after a major engagement campaign to encourage farmers to determine the risk of Johnes disease to their dairy herds and the current disease status of their herds. Six strategic control options were offered to farmers using a web based herd health management tool (myhealthyherd.com) to help farmers and their veterinary surgeons decide on the most appropriate course of action to manage Johnes Disease in their herds. Once the risks of disease entering the herd and spreading within the herd were established, the current prevalence of Johnes infection was estimated and an appropriate control strategy planned. The risks, prevalence and control option were recorded on a central database and analysed for the purposes of this paper.

Results: Of the herds that were found to be significantly infected with MAP and which selected one of the six options for control, 50% opted to use quarterly milk testing and a risk based control strategy to manage the disease, 20% opted to improve farm management and use single annual testing to identify and manage high risk cows, and 18% chose to improve farm management for all cows without any testing. 8% opted for a traditional test and immediate cull policy. Only 2% decided to vaccinate, and only a few farms used terminal sires and the purchase of replacements to manage the disease.

Conclusions: The study demonstrates that no single management or control strategy suits all dairy herds in all circumstances. Limitations of resources, and differences in aspirations between farms and farmers suggests that different strategic options must be offered for the prevention, control and management of Johnes Disease in dairy herds. The most popular strategic option selected by veterinary surgeons and dairy farmers involved the quarterly testing of all cows and the management of high risk cows to prevent new infections.

Public Health

P02-002-165

Prevalence and characterization of Verocytotoxin-producing *Escherichia coli* (VTEC) in cattle of Northern Italy

Valentina Bianchini¹Anna Zugnoni¹Gianluigi Ardissino²Stefano Morabito³Gaia Scavia³Francesca Tel²Mario Vittorio Luini^{1*}

¹Istituto Zooprofilattico Sperimentale della Lombardia e dell'Emilia Romagna - Sezione di Lodi, Lodi, ²Centro per la Cura e lo Studio della Sindrome Emolitico Uremica, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, ³Istituto Superiore di Sanità, National Reference Laboratory for *E. coli*, Rome, Italy

Objectives: VTEC are agents of diarrhea and hemorrhagic colitis in humans, which can result in a hemolytic uremic syndrome (HUS). Serogroups more frequently associated with human infections are O157, O26, O111, O103, O145 (top-5). Ruminants are the natural reservoir of VTEC. The shedding of VTEC in cattle appears to be influenced by age of the animals, season, diet, housing and stress.

Aims of the study were to a) determine the prevalence of VTEC in feces of cattle of different age and attitude of Northern Italy; b) investigate the characteristics of the strains in term of virulence traits (vtx, eae) and serogroups.

Materials and Methods: Fecal samples were collected between June and October 2015 in 43 dairy herds and 19 beef farms of the Lombardy Region. In each dairy herd 6 calves (less than 30 days), 6 heifers and 6 milking cows were individually sampled. In beef farms feces of 6 fattening veals or 6 fattening bulls were collected. Analysis were performed in pools of 3 animals of the same class for a total of 82, 86, 87, 12 and 26 samples respectively in dairy calves, heifers or cows and fattening veals or bulls. Feces were directly plated onto MacConkey agar and enriched in 0.1% peptone water (PW) and plated onto TBX agar. DNA was extracted from PW and positive signals for vtx1, vtx2 and eae genes, as well as for the top-five serogroups were demonstrated with a Real-Time PCR. VTEC isolation from vtx-positive samples was attempted by analyzing 50 colonies from MacConkey agar and from TBX agar plates. Results were expressed as in the ISO13136/2012 as "presumptive presence" in case of positivity for vtx genes without isolation and "presence" in case of successful isolation. 13 serogroups more frequently associated with human infection were searched on isolated strains. Chi-square test was applied to compare the prevalence of VTEC isolation in different classes of animals.

Results: In all the farms the presumptive presence of VTEC was recorded and VTEC were isolated from 53 out of 62 herds, for a total of 157 strains. Overall, the herd prevalence of VTEC (presence confirmed by isolation) was 95.2% (CI95%: 88.8-100%) and 68.4% (CI95%: 47.5-89.3%) in dairy and beef herds, respectively. The genes associated with the top-5 serogroups was frequently detected in fecal samples (in all the herds at least one sample showed a positive PCR signal for at least one of the top-5 serogroup). However, the majority of the isolates did not belong to serogroups commonly found in humans and only 17 strains were positive for the presence of eae and vtx2 or eae, vtx1 and vtx2, gene combinations associated to more severe illness. In 9 herds VTEC of top-five serogroups were isolated, but only in 3 of them the strains were positive for the presence of vtx2 or vtx1 and vtx2 and in particular they belonged to the O157 serogroup.

Prevalence of VTEC (confirmed by isolation) was 42.6% in calves, 60.5% in heifers, 21.8% in cows, 8.3% in fattening veals and 69.2% in fattening bulls. The frequency of VTEC isolation resulted significantly higher in heifers than in calves or cows ($p < 0.05$), as well as in fattening bulls than in fattening veals ($p < 0.01$). VTEC carrying eae gene was isolated in 23

samples from calves, 8 from heifers, 6 from cows, 4 from fattening bulls and no one from fattening veals. The frequency of isolation of VTEC eae-positive was significantly higher in calves than in heifers or cows ($p < 0.01$) and this is mainly associated with the isolation of eae-vtx1 strains.

Conclusions: Differences among class/age of animals in term of VTEC prevalence and strains characteristics were observed. Our results confirm a large presence of VTEC in cattle, but a low presence of strains positive for eae and vtx2 or eae, vtx1 and vtx2 or belonging to the "top five" serogroups, which are more often associated with cases of severe human illness. Genotyping of the strains, including the analysis of additional virulence factors, is in progress and the comparison with human isolates collected in the same area and period will be performed to better understand the possible link with human infections.

Public Health

P02-002-166

Serological survey for porcine cysticercosis and associated risk factors in pigs slaughtered at Ndumbuini abattoir in Nairobi, Kenya

James Akoko^{1,1*}Ewan T. MacLeod²Pablo L. Alarcon³Eric M. Fevre⁴

¹Biosciences, International Livestock Research Institute, Nairobi, Kenya, ²Biological sciences, International Animal Health, University of Edinburgh, Edinburgh, ³Veterinary epidemiology, economics and public health, The Royal Veterinary College, University of London, London, ⁴Veterinary Infectious Diseases, University of Liverpool, Liverpool, United Kingdom

Objectives: Cysticercosis is a serious public health risk in both rural and urban areas. Eastern and southern Africa has experienced a recent rapid growth in pig production, with increasing number of cysticercosis reports. But Cysticercosis is neglected in Kenya, with scarce data. The objectives of the project were to: estimate the seroprevalence of cysticercosis; map the value chains associated with the abattoir; and assess the risk of cysticercosis-infected pork entering Nairobi food system.

Materials and Methods: This study was conducted at Ndumbuini, the main abattoir supplying pork to middle-low income consumers in Nairobi. Blood samples were obtained from 700 pigs selected by systematic random sampling. Antigen ELISA was used to detect *T. solium* secretory antigen. Focus group discussions and individual interviews were conducted to get information for value chain analysis and understand the risk of cysticercosis-infected pork getting into the Nairobi food system. A total of 60 Pork butcheries in Nairobi were also visited and a structured questionnaire administered to understand how pork is handled at the butchery and the preferred cooking methods.

Results: The overall sero-prevalence of cysticercosis was estimated at 8.5% (95% CI: 6.4-10.7%). Pigs originated from 11 different counties. The prevalence rates ranged between 0-36%. Seven counties had seropositive pigs, four showed no positives. There was significant differences between sex ($p=1$) or age ($p=0.13$) of the pigs sampled. No positive cases were detected by post-mortem meat inspection. Therefore, all the carcasses were passed for human consumption. The abattoir had no facilities for treating *Cysticercus solium* infected carcasses.

Pork is mainly transported from the abattoir at room temperature (97%), majority of retailer (87%) keep pork at room temperature and cysticercosis awareness level is very low (10%).

The highest risk of consuming infected pork from Ndumbuini is in Nairobi County, which receives the largest percentage of pork (69.43%), Kiambu (14.22%), Nakuru (8.87%) and Kajiado (6.59%).

Conclusions: This study highlights that *T. solium* is a public health risk to consumers of pork from Ndumbuini abattoir. We therefore recommend that meat inspection by palpation and incision to be complemented with rapid tests. A multi-sectorial, One Health Approach should be conducted to sensitize communities on control strategies like proper cooking methods, improved food hygiene and sanitation, accompanied with studies to determine the risk factors of *T. solium* transmission in both pigs and people.

P02-002-167

Use of mycotoxin binders and aflatoxin M1 detection in raw milk

Raul Ortiz-Martinez^{1*} Claudia Miranda-Castañeda¹ Arturo Valdivia-Flores¹ Teodulo Quezada-Tristan¹ Ma Carolina De Luna-Lopez¹

¹Universidad autonoma de Aguascalientes, AGUASCALIENTES. AGS, Mexico

Objectives: Aflatoxins are toxic secondary metabolites produced by species of *Aspergillus*. The most extensively investigated aflatoxins are aflatoxin B1 and aflatoxin M₁, because according with the IARC they are carcinogenic and potentially carcinogenic for humans, respectively. Since the AFM₁ is a metabolite of AFB₁ eliminated through milk, AFM₁ levels in milk are an excellent biomarker to AFB₁ consumption.

In order to determine if mycotoxin binders added to feed cattle could reduce AFM1 in field conditions, a descriptive and longitudinal study was performed in three dairy farms.

Materials and Methods: The cattle feed in the dairy farms was naturally contaminated with aflatoxins. Five mycotoxin binders called "broad spectrum binders (bentonite, montmorillonite, aluminosilicate, clay and glucomannans) were used during 24 months. The dairy farms owners gave their consent to sampling the milk twice a month.

The milk samples were preserved in refrigerated storage and analyzed in The Research Laboratory of Universidad Autonoma de Aguascalientes, Mexico. To determinate AFM1 concentration in milk samples, competitive ELISA kits were used.

Results: The results show that 54.16% of all milk samples had detectable AFM1 levels. No sample exceeded the maximum allowed limit (0.5 mg / L) established by the Norma Oficial Mexicana but 27.31% exceeded the maximum allowed limit (0.05 µg/L) set by European Union.

The results show that binders were effective to maintain the AFM1 levels below of Norma Oficial Mexicana but not for more strict regulations such as the one set by the European Union. These results apply to the three dairy farms. The dairy farms used mycotoxin binder according to labeled directions, showed a tendency to diminish AFM1 level.

Conclusions: According to results, milk or milk products consumers are in potential risk due to AFM1 is not being denaturalized by pasteurization or boiling. None of the process reach a high temperature to destroy AFM1.

P02-002-169

Bioaccumulation of Cd and Pb in plant tissues (root, stem and leaves) of grassland in oil producing region of Magdalena Medio, Colombia.

Manuel Pelaez-Pelaez¹ Amanda Chaparro-García² Jhon J Bustamante-Cano³ Pilar Alonso⁴ Jose Ramiro Gonzalez-Montaña^{5*}

¹Agronomic Engineering Program, National University, Palmira,

²Department of Biology - Chemistry, ³Department of Veterinary

Medicine and Animal Science, University of Pamplona, Pamplona,

Colombia, ⁴University of León, Spain, León, Spain, ⁵Department of

Veterinary Medicine and Animal Science, University of León, Spain,

León, Spain

Objectives: The aim is to estimate the frequency of plants in tropical grassland of the region of Magdalena Medio (Colombia) there are two economic activities: intensive livestock and a consolidated petrochemical industry. These activities thrown into the environment large amounts of toxic metals: such as lead and cadmium, which pollute soils and grassland. We try to establish the relationship between the presence of heavy metals (Cd and Pb) in topsoil, and the response of these plants to the accumulation of heavy metals. Finally we determine the contents of cadmium and lead in different plant tissues settled in the area.

Materials and Methods: It has been done an inventory of soil and pastures to distances of 100, 500, 2500 and 5000 m, from the sources of pollution (oil wells of Yondo-Antioquia, crude oil refinery of Barrancabermeja and Campus of the University La Paz, Barrancabermeja-Santander). Other aspects: such as soil depth (5 to 30 cm), type of grass, part of the plant (root, stem and leaves) and distance from the source of contamination were taken into account.

Plant and soil samples were conducted during the dry season in June 2013. Samples were processed by atomic absorption spectrophotometer (Varian Spectra AA 20FS) used for the determination of metals, equipped with a lamp hollow cathode appropriate for each element, and a deuterium lamp for background correction.

Results: Seven species of *Brachiaria* have been detected. They are tropical grasses adapted to soils with heavy metals such as Cd and Pb. In the area of refinery B. decumbens were detected, alternating with B. humidicola and B. brizantha. In the area of oil wells and the area control they presented more often other species. Both the distance to the emitting source, such as the sampled area showed a statistically significant effect on the bioaccumulation of Pb. This metal bioaccumulates at very high concentrations, preferably in the roots, and then the stems.

In coming to the oil refinery fields and in transects of 100 and 500 m, it was where the greatest gradients of Pb contamination occurred. In the case of Cd on stalks as bioconcentration it involves both refining zones and in oil wells, and especially in the roots. In the bioaccumulation of Cd no noticeable decrease due to the distance to the emitting source.

Conclusions: It has demonstrated the adaptation of *Brachiaria* to soils with high persistence of heavy metals, especially in their first 5 cm, with great bioaccumulation of Cd and Pb, and especially their root systems.

P02-002-170

Selective Androgen Receptor Modulators (Sarms): Zootechnical Effects And Analytical Strategies To Detect Their Administration In Calves

Nora Cesbron^{1,*} Gaud Dervilly-Pinel¹ Cédric Vernet¹ Alexandre Sydor¹ Mylène Penot¹ Audrey Gicqiau¹ Stéphanie Prévost¹ Bruno Le Bizec¹

¹LABERCA, 44307 Nantes Cedex 03, France, France

Objectives: Selective androgen receptor modulators (SARMs) are a novel class of androgen receptor ligands. They are intended to exhibit the same kind of effect as androgenic drugs but be much more selective in their action. They will also have a high potential for misuse in breeding practice. In order to guaranty the consumers with food from animal origin free from any residues, studies about SARMs and analytical strategies are required to ensure safe food. Two objectives will be carried out: 1- to investigate SARMs zootechnical performances in calves, 2- to study SARMs kinetic of elimination and metabolism in calves urine and feces.

Materials and Methods: An animal trial was carried on under approval of the French Ethical Committee at the Center of Research and Preclinical Investigation (CRIP of Oniris). Twelve Prim'Holstein entire male weaned calves were purchased to establish a protocol for assessing the repeatability of seven parameters to allow describing and quantifying their growth and development (live weight gain, growth rate, intake efficiency, width of hips, girth circumference, pelvis muscle depth, size and Body Condition Score). Five measurements per parameters were realized/repeated. All animals were followed clinically every day, urines and feces collected by the same operator. Among these twelve calves, ten of them have been selected to create a "treated" group (n = 5) and a "control" group (n = 5) to study the zootechnical effects after an oral administration of enobosarm. In the same time, the kinetic of enobosarm elimination was established and the metabolism investigated after oral administration at either a concentration of 1 mg/kg (1 ppm "low dose") or with a calf orally "treated" once with 200 mg on one-shot ("high dose"). Liquid chromatography hyphenated to a tandem mass spectrometry (LC-MS/MS) was conducted using a ultra-high pressure liquid chromatography (UHPLC) on reversed-phase separation equipped with an Acquity UPLC BEH C18 column and connected with a mass spectrometry detection in electrospray ionization (ESI) negative mode with a triple quadrupole (QqQ) Xevo TQ-S.

Results: Beside the physiological growth of calves, measures of body weight (BW), growth rate (ADG) and feed efficiency (FC) showed no significant difference in growth between treated and control groups. Similarly, no significant stature growth difference between treated group and control group could be observed on others measurements performed. In urine and feces, the drug could be identified very shortly after oral administration. At the "high dose", the urine concentration of free form of enobosarm was between 0,24 and 38 ng/mL with a maximum at D+5H. After 5 days, enobosarm could not be detected anymore. The concentration of the total forms of enobosarm was detected between 0,25 and 155 ng/mL with a maximum at D1. After deconjugation, enobosarm could be detected with a low level until nine days. During the 21 days of treatment at the "low dose" the average level of free form of enobosarm was between 0,18 and 1,2 ng/mL. And the total forms of enobosarm was detected with an average concentration between 0,4 and 2,8 ng/mL. In feces, with the "high dose", only free form of enobosarm was always and very comfortably identifiable and quantifiable during the 21 days of the experiment. Concentrations ranging from about 50 000 ng/g to 20 ng/g never dropped below the limits of detection and quantification. With the "low dose", the free form of enobosarm was also identifiable and quantifiable in feces throughout the 21 days of the experiment. The fecal

concentration of enobosarm increased the first three days up to 1800 ng/g and then stabilized from D4 to a plateau of about 1200 ng/g.

Conclusions: Results obtained by analytical strategies allowed to demonstrate a strong fecal excretion of enobosarm, the concentrations are higher in the feces compared to urine samples. Such results are particularly promising in the objective of setting up an analytical strategy and a target matrix to highlight SARMs abuse in livestock animals. Next step is to develop an analytical strategy with a LC-MS based metabolomics approach to allow profiling biological matrices, to reveal biological effects for implementing a robust statistical model to predict illegal use of this novel class of anabolic agents in calves.

P02-002-171

Awareness, Attitude and Practices towards Brucellosis among the community in Kiptome location, Kericho District, Kenya

Edinah Cherotich^{1,*}

¹Ministry of Agriculture, Livestock and Fisheries, Kenya, Nairobi, Kenya

Objectives:

1. To determine the awareness of brucellosis among the community members within the study area
2. To determine the attitude of the community members towards brucellosis within the study area
3. To determine the practices of the community members towards brucellosis within the study area

Materials and Methods: This study was conducted among the household heads in Kiptome Location, Kericho District, Kenya. Descriptive cross sectional study design was employed. A systematic random sampling method was used to identify 423 household heads for the study. Information on personal data, awareness, attitude and practices towards management of brucellosis was collected using a questionnaire. The data was analysed using Statistical Package for Social Sciences (SPSS) version 17. Ninety five percent confidence intervals (95% CI) and two-tailed p-value was calculated to assess significance of results.

Results: The results showed that (303) 71.6% of the respondents had adequate awareness of brucellosis. There was a high rate of 'positive' attitude towards brucellosis with (315) 74.5% of the respondents having positive attitude and (264) 64.8% of the respondents had good practices in regard to the management of brucellosis. Level of education positively affected awareness, attitude and practice of the community towards brucellosis (p< 0.05). Primary level of education was significantly associated with good practice with respect to brucellosis (p=0.005).

Conclusions: There was adequate awareness of brucellosis, high rate of positive attitude and good practices towards the management of brucellosis among the respondents. The non-sanitary practices like the lack of use of protective devises while handling aborted fetuses and the non-use of parturition pens for livestock, in regard to the control of brucellosis can predispose the community members to the disease. This study recommends that education and awareness of brucellosis should particularly focus on the improvement of the use of parturition pens and handling of aborted fetuses and other materials from pregnant animals.

Reproduction

Comparison Between Techniques By Per Rectal Palpation For Pregnancy Diagnosis On Pregnancy Loss, Calving Rates And Abnormalities In Newborn Calves

Juan Romano^{1,2,3,*} and Pablo Pinedo², Kelsey Bryan², Roney S. Ramos², Karol G. Solano³, Daniel Merchan³, Juan Velez³

¹Large Animal Clinical Sciences, College of Veterinary Medicine & Biomedical Sciences - Texas A&M University, College Station, Texas 77843-4475, ²Texas A&M AgriLife Research, 6500 Amarillo Blvd West, Amarillo, TX 79106, ³Aurora Organic Dairy, Cold Water Farm, 5490 County Road Y, Startford, TX 79084, United States

Objectives: The objectives of the present investigation were to evaluate the pregnancy diagnosis by detection of either the allantochorion membrane (FMS) or amniotic sac (ASP) by per rectum palpation (PRP) during late embryonic or early fetal period on pregnancy loss (PRL) at reexamination, calving rates, and abnormalities in newborn calves

Materials and Methods: A controlled randomized blind design with 800 lactating dairy pregnant cows diagnosed by transrectal ultrasonography (TRUS) between days 35 and 57 of gestation from one dairy farm were included. The cows were randomly divided according to detection of allantochorion membrane (FMS group; n= 264), detection of amniotic sac (ASP group; n= 266), and TRUS (control [CON] group; n=270). TRUS was considered as the criterion standard method of comparison. The entire PRP was performed by one experienced veterinarian. Then, all the cows were reexamined only by TRUS between 2 and 4 weeks later by two independent veterinarians to assess PRL. The calving rate one (number of cows calved/number of cows initially pregnant) and calving rate two (number of cows calved/number of cows pregnant at reexamination) for each group was calculated. All abortions and stillborn were necropsied, and calves alive were followed for 5 days.

Results: The overall initial PRL (between initial pregnant cows and reexamination) for FMS, ASP, and CON groups was 7.4% (19/258), 8.8% (23/262), and 9.2% (24/260), respectively (P=0.75). The number of missing animals between initial pregnancy diagnosis and reexamination from groups FMS, ASP, and CON was 6, 4, and 10, respectively (P=0.25). The overall late PRL (between reexamination and calving) for FMS, ASP, and CON groups was 4.2% (9/213), 5.7% (12/209), and 4.2% (9/216), respectively (P=0.71). The number of missing animals from reexamination to calving from groups FMS, ASP, and CON was 26, 30, and 20, respectively (P=0.43). The calving rate one for FMS, ASP, and TRUS groups was 79.1% (204/258), 75.2% (197/262), and 79.6% (207/260), respectively (P=0.63). The calving rate two for the same groups was 85.4% (204/239), 82.4% (197/239), and 87.7% (207/236), respectively (P=0.27). The number of fetuses aborted late, premature, and mature dead from FMS, ASP and CON groups was 6, 4, and 5, respectively (P=0.85), and no abnormalities at necropsy were detected. One stillborn male calf with atresia coli after 281 d of gestation from a cow examined by ASP at day 51 was diagnosed.

Conclusions: It was concluded that the use of either FMS or ASP for pregnancy diagnosis during late embryonic or early fetal period did not increase the PRL, affect calving rates, or produce calves with congenital abnormalities.

Effect on pregnancy rate and association between CL and follicle sizes and fertility in beef cows subjected to a timed AI protocol, Shortsynch

Hisashi Funakura¹ Takeshi Osawa^{1,2,*} Yuji Tsubakishita² Ayumi Shiki² Takashi Ekawa² Koichiro Hemmi³ Ikuo Kobayashi³ Mizuho Uematsu⁴ Shogo Mido¹ Hiromu Katamoto^{1,2} Go Kitahara²

¹Graduate School of Medicine and Veterinary Medicine, ²Department of Veterinary Sciences, ³Field Science Center, University of Miyazaki, ⁴Department of Production Medicine, Nosai Miyazaki, Miyazaki, Japan

Objectives: Although prostaglandin F2a (PG) has been widely used for induction of estrus in beef as well as dairy cows, treated animals are often not inseminated because induced estrus is not detected. Shortsynch is a protocol that includes injection of PG to the animals having a corpus luteum (CL) (day 0) and GnRH injection 48-56 h later (day 2) followed by timed artificial insemination (TAI) 16-20 h later (day 3). The objective of the study was to elucidate effect of Shortsynch on pregnancy rate (PR = CR x estrus detection rate) and association between CL and follicle sizes and conception rate (CR) in Japanese Black cows subjected to the protocol.

Materials and Methods: Experiment 1: A total of 272 postpartum Japanese Black cows having a CL 18 mm or greater in diameter were randomly divided into two groups; those subjected to Shortsynch and TAI (SSTAI, n = 134) and those injected with PG and inseminated after estrus detection (PGAI, n = 138). Size of CL was evaluated by ultrasonography with a linear probe of 10.0 MHz. Pregnancy diagnosis was made by ultrasonography 30 to 50 days after AI. CR and PR were compared between the two groups. Experiment 2: A total of 38 postpartum Japanese Black cows having a CL 18 mm or greater in diameter were subjected to Shortsynch and TAI. Diameters (average of the major and minor axes) of CL and the largest follicle and volume calculated by a formula for ellipsoid volume were recorded and plasma samples were collected on days 0, 2 and 9. Plasma progesterone concentrations were determined with a validated enzyme-linked fluorescent assay (miniVIDAS; bioMerieux, Marcy l'Etoile, France). CL and follicular sizes and progesterone levels were compared between subsequently pregnant and non-pregnant cows. Receiver operating curve was used to identify the optimal cutoff point of CL size for fertility.

Results: Experiment 1: While no difference was found in CR between SSTAI (81/134, 60.4%) and PGAI (71/120, 59.2%), PR in SSTAI (60.4%) tended to be higher than that in PGAI (71/120, 51.4%) (P = 0.09). Experiment 2: Progesterone concentrations on day 0 were 9.7 ± 3.0 ng/ml, and higher than 1.0 ng/ml in all of the animals. CR (PR) was 60.5% (23/38). Diameter of CL on day 0 in pregnant cows (20.8 ± 1.4 mm) was greater (P < 0.05) than that in non-pregnant cows (19.8 ± 1.6 mm). Volume of CL on day 0 in pregnant cows (4.11 ± 0.77 cm³) was also greater (P < 0.01) than that in non-pregnant cows (3.24 ± 0.80 cm³). The optimal cutoff points of CL diameter and CL volume for fertility were 19.8 mm and 3.61 cm³, respectively. Diameter of the largest follicle in pregnant cows (10.0 ± 2.5 mm) was similar to that in non-pregnant cows (9.1 ± 1.7 mm) on day 0. On day 2, however, the diameter in pregnant cows (12.4 ± 1.8 mm) was larger (P < 0.05) than that in non-pregnant cows (11.1 ± 2.1 mm). Progesterone concentrations on day 9 in pregnant cows were higher (P < 0.05) than those in non-pregnant cows.

Conclusions: In conclusion, application of Shortsynch is effective in improving PR, and use of ultrasonography for accurate evaluation of CL and follicle sizes during the protocol process could help to increase CR in cows with a functional CL.

Detection of bovine leukemia virus antibodies in receptive cows

Edviges M. Pituco¹, Eliana De Stefano^{2,3}, Líria H. Okuda³, Adriana N. Romaldini³, Cláudia P. Ribeiro³

¹Laboratório de viroses de bovídeos, Instituto Biológico, São Paulo,

²Laboratório de viroses de bovídeos, ³Laboratory of Bovine viruses, Instituto Biológico, São Paulo/São Paulo, Brazil

Objectives: The causative agent of enzootic bovine leukosis (EBL) is the Bovine leukemia virus (BLV) a retrovirus that infects beef and dairy cattle. It is a major animal health problem worldwide causing important economic losses and this agent is able to cross transplacental barrier. Enzootic bovine leukosis can lead to losses as inability to export cattle, semen and embryos to countries that maintain BLV control programs. Further losses may include reduced reproductive efficiency and decreased milk production. The aim of this study was to select bovine receptive for embryo BLV negatives.

Materials and Methods: The serum samples were of receptive cows from an embryo transfer program in order to establish performance standards for the embryo transfer industry to ensure the accuracy and completeness of all records pertaining to the parentage of resulting offspring. A total of 3895 serum samples of cows above 24 months, mixed breed cattle, were analyzed with the aim to select the BLV negative for the program. Samples were analyzed by AGID in accordance to OIE, at Bovid Viruses Laboratory of Instituto Biológico, São Paulo.

Results: The frequency of BLV positives by AGID were 5,8% (226/3895). None of the animals showed clinical signs indicating that were asymptomatic carriers of the virus. Only BLV negative cows were selected to embryo transfer program. In Brazil, the frequency of positive animals varies considerably between the states considering the breeding, dairy or beef cattle, and management. Sero-epidemiological surveys have been demonstrated rates between 9,0% and 54%, showing that BLV is widespread and measures to contain the infection need to be taken.

Conclusions: The sanitary control for BLV in embryo transfer program is important to mitigate the risk of spread and prevent the cycle of transmission of disease by transplacental and horizontal vials. So, to avoid losses caused by infection.

P02-002-176

Comparison of Carotenoid Contents in the Blood and Follicular Fluid of Japanese Brown Cattle During and After the Grazing Period

Chikako Tani¹, Takashi Maoka², Mineto Tani³, Yasuo Moritomo³, Toru Okada⁴, Go Kitahara¹, Hiromu Katamoto¹

¹University of Miyazaki, Miyazaki, ²Research Institute for Production Development, Kyoto, ³Tokai University, Kumamoto, ⁴ASKA Animal Health Co., Ltd., Tokyo, Japan

Objectives: Carotenoids are important nutrients not only for humans, but also for animals. Carotenoids enhance immunity and reproductive

performance for livestock. Fat soluble vitamins and β -carotene enhance bovine ovarian function, follicles and embryos. Carotenoids show excellent singlet oxygen quenching activity, and have a protective effect against UV light. However the function of carotenoids in cattle is not clear enough. The aim of the present study was to investigate comparison of carotenoid contents during and after the grazing period.

Materials and Methods: Three Japanese Brown cattle, which were born on the farm of the Faculty of Agriculture at Tokai University, were used in this study. The test period was divided into two periods, based on the grazing seasons (During: during the grazing season in October of 2014, n=5; After: after the grazing season in November of 2014, n=6). Cattle were fed 10 kg of green grass dry matter (DM) per day per head on grasslands in the Aso region during the grazing period, and 8 kg of silage DM per day per head in the barn after the grazing period. An investigation into the accumulation of carotenoids from feed was carried out. The accumulated carotenoid contents at the estrous period in the blood and follicular fluid were observed. Blood estradiol level (E_2) and progesterone level (P_4) was measured.

Results: Among the accumulated carotenoid contents in the blood and follicular fluid at the estrous period, β -carotene was presented as a major component along with lutein. In the blood, the lower β -carotene level in the After period was observed as (918.7 ± 290.3 ng/mL) compared with that in the During period as (4325.4 ± 1000.9 ng/mL, $P < 0.01$). In addition a lower lutein level was observed in the After period as (15.1 ± 7.6 ng/mL) compared with that in the During period as (189.0 ± 41.7 ng/mL, $P < 0.01$). Although there is no statistical significance, a lower β -carotene level of the follicular fluid was observed in the After period as (968.5 ng/mL \pm 162.8 ng/mL) compared with in the During period as (1493.0 ng/mL \pm 681.3 ng/mL, $P = 0.10$). However a lower lutein level was observed in the After period as (11.4 ± 5.7 ng/mL) compared with that in the During period as (63.9 ± 40.2 ng/mL, $P < 0.05$). Moreover in estimating follicular accumulated concentration, a lower lutein level in the After period was calculated compared with that in the During period (16.0 ± 13.2 μ g vs. 77.2 ± 62.5 μ g, $P < 0.05$). The β -carotene concentration included in the silage is one-seventh to one-twelfth that of fresh green grass and the lutein concentration was one-fifth to one-tenth. Moreover a small amount of β -cryptoxanthin was detected in the corn, and a small amount of zeaxanthin was detected in the silage. Although there was no difference in blood E_2 and P_4 levels between the two periods, β -carotene and lutein levels were lower after the grazing period than during it.

Conclusions: These studies indicate that carotenoids concentration of blood and follicular fluid is dependent on the carotenoids concentration in the feed. It was found that in the grazing periods (from April to October) grazing cattle took in carotenoids (β -carotene 2g/day, lutein 0.5g/day). The ideal calving season in Japan is in April. Cattle which deliver in April can eat a sufficient amount of fresh green grass for six months. Carotenoids might be especially necessary for bovine calving, milk secretion, conception and maintaining pregnancy. Therefore more carotenoids might be necessary for breeding cattle which cannot be fed enough fresh green grass.

Bovine Obstetric Events attended by New Zealand Veterinarians and Risk Factors Associated with Method of Calf Delivery

Jaimie Hunnam¹, Ray Castle², Scott McDougall³

¹Biosecurity, Agriculture, Energy and Resources, Department of Economic Development, Jobs, Transport and Resources, Attwood,

Australia, ²Bayer Animal Health, Bayer New Zealand, Auckland, ³Cognosco, AnexaFVC, Morrinsville, New Zealand

Objectives: Approximately 4.8 million dairy cows calve annually in New Zealand (NZ). Anecdotally, veterinarians are called to assist in a significant number of these calving events. To date little data has been published on neither the types of dystocia for which veterinary assistance is sought, nor the treatment protocols chosen by veterinarians. The objectives of this study were to:

1. Describe, at a national level, the relative frequency of different types of dystocia for which veterinary assistance is sought.
2. Describe the relative frequency of, and risk factors associated with, the use of each type of calf delivery method by veterinarians in NZ.

Materials and Methods: Data on calving and uterine prolapse events was entered on a voluntary basis by veterinarians (vet) into an online reporting system (www.calvingcup.bayer.co.nz) from the 10th June 2014 to the 31st October 2014.

A calving event occurred if one or more calves were delivered by the vet. The vet recorded the obstetric situation they were presented with, the method used to deliver the calf, the date, and the regional location of the event. The country and year of vet graduation, and whether that vet was a new graduate were also listed. The number and percentage of vets or events, by each risk factor, were described.

Each method of delivery (correction/traction, foetotomy or caesarean) was dichotomized into whether the method was used or not used, with a separate model run for each outcome. Non-normally distributed risk factors were summarized using the mean and standard deviation. Risk factors were screened using a t-test, Chi-squared test, or Fisher's exact test and those associated ($p < 0.2$) were included in multivariable regression analysis.

A backwards stepwise model-building process was used to develop mixed effect logistic regression models, with vet included as a random effect. Variables were retained if they were associated with $p < 0.05$, derived from a likelihood-ratio test. Biologically plausible interaction terms between main-effects variables were considered for inclusion in each model.

Results: 9792 events were recorded as a "calving" by 371 dairy vets. The most common causes of veterinary attendance were a foetal head or leg(s) back, foeto-pelvic disproportion, and lack of vaginal/cervical dilatation +/- uterine inertia. Foeto-pelvic disproportion and maternal pelvic deformity/fracture occurred significantly later in the season compared to foetal head back presentation. Over 80% of cases of posterior presentation, hydroallantois/hydrops, multiple pregnancy, failure of cervical/vaginal dilatation +/- uterine inertia, breech presentation, or twisted uterus were rectified via correction of malpresentation +/- traction. The presentations for which caesarean section was most commonly used were shistosoma reflexus (caesareans performed in 20.5% of events), maternal pelvic deformity/fracture (19.6%) or foeto-pelvic disproportion (12.4%). Relative to foetal head back, (the most common dystocia recorded), shistosoma reflexus (OR = 30.64), maternal pelvic deformity/fracture (OR = 30.18), foeto-pelvic disproportion (OR = 17.67), and twisted uterus (OR = 15.70) were significantly more likely to be delivered via caesarean. Foetotomies were significantly more likely to be performed in the South Island regions (OR = 2.54 - 3.86) relative to the reference category of the Waikato/Bay of Plenty Region (Central North Island). Relative to new graduates, more experienced vets (except those graduated prior to 1979 and between 1990-1994), were significantly more likely to perform a caesarean (OR = 1.66 - 2.80).

Conclusions: This report describes a substantial dataset on veterinary assisted dystocia events in NZ. The type of dystocia, regional location, the country of the vet's training, and the vet's level of experience were

all significantly associated with which method was chosen to deliver the calf. This study also introduces a novel on-line technique for collecting large volumes of clinical data.

Comparative global gene expression profile of developmental related genes in parthenogenetic and in-vitro fertilized caprine embryos

Sadhan Bag ¹, Renu Sing ¹, Kuldeep Kumar ¹, Puspendra Mohapatra ¹, Pranjali Agarwal ¹, Bikash C. Das ¹

¹ICAR-IVRI, Bareilly, India

Objectives: To examine the global gene expression profile to search differentially expressed genes between parthenogenetic and in-vitro fertilized (IVF) morula by using microarray analysis and validated by relative real time PCR (qPCR) in caprine species

Materials and Methods: Production of parthenogenetic and IVF embryos.

Parthenogenetic and IVF embryos were produced as per the method described by Singh et al, (2013).

Microarray analysis

For microarray analysis, diploid parthenogenetic and IVF embryos of morula (50 pooled embryos) stage were picked up from the culture medium separately and washed with 1X PBS. Two replicates of each group were taken for microarray study. Microarray data were normalized across arrays to perform direct comparisons of probe set values between samples. GeneSpring GX 11.5 microarray data analysis tool was used to identify differentially expressed transcripts. For a given comparison, IVF derived embryos was selected as the baseline reference, and transcripts that exhibited various fold change relative to the baseline were considered differentially expressed. The unpaired t-test method was applied and p-value cut off 0.05 was considered statistically significant. Some of the genes were validated using real time PCR. For comparison of gene expression of diploid parthenogenetic embryos with IVF embryos, the relative expression of data was analyzed using SPSS software and P-value < 0.05 was considered significant.

Results: According to the microarray analysis, the total number of up regulated (UR) and downregulated (DR) genes was 613 and 220, respectively in diploid parthenogenetic morula as compared with IVF morula. The number of genes showing about two-, two- to five-, five- to 10-, 10- to 20-, and above 20-fold UR and DR genes was 147, 229, 122, 59, and 56 and 94, 73, 18, 13, and 22, respectively. Five UR genes validated (PTEN, PHF3, CTNNB1, SELK, and NPDC1) and all of them were significantly higher in parthenotes, which was in accordance with microarray results, whereas the expression of DR (AURKC and KLF15) genes were downregulated in parthenotes as observed in microarray results but the difference was not significant ($P < 0.05$).

Conclusions: In conclusion, our findings demonstrate differential expression of a large number of genes in parthenotes compared with IVF embryos, which may be the reason for aberrant parthenogenetic embryo development in caprine species.

Absence of association between pre and post partum energy status and genital tract inflammation in dairy cows

Louise Gros¹ Lucile Peuch² Christian Engel³ Jantijn Swinkels⁴ Pierre-Hugues Pitel⁵ Sylvie Chastant-Maillard^{1,*}

¹UMR INRA/ENVN, Toulouse, France, ²Reproduction, UMR INRA/ENVN, Toulouse, ³Clinique vétérinaire de la Rance, Broons, France, ⁴MSD Animal Health, Boxmeer, Netherlands, ⁵LABEO Franck Duncombe, Caen, France

Objectives: Inflammation of the genital tract, i.e. persistent inflammation of the uterus and/or the cervix is one major limiting factors of reproduction in dairy cows. Negative energy balance, both pre- and post-partum, belongs to the main risk factors for genital inflammation. Its early diagnosis could allow at the individual level, an early detection of at-risk cows together with, at the herd level, the evaluation of the quality of the transition period management. The objective of the study was to evaluate the value of several markers of negative energy balance, for the prediction of genital inflammation.

Materials and Methods: Markers of energy balance were selected based on their applicability whereas genital tract inflammation was diagnosed and quantified using uterine and cervical cytology. Samples and data were collected over a 3-months period from 133 cows from 10 herds (Brittany, France). 14 to 3 days before calving, body condition was scored (0-5 scale; BCS) and blood was collected on dry tubes from the coccygeal vein for non esterified fatty acids (NEFA) measurement. Between 3-14 days after calving, BCS and blood (NEFA measurement) were collected and beta hydroxybutyrate (BHB) assayed with a cow-side strip test (Optium Xceed, Abbott, Rungis, France). Blood was stored at -4°C until centrifugation, and serum frozen at -20°C until analysis. NEFA were assayed by spectrophotometry (Diaglobal, Berlin, Germany). With this method, the blood NEFA concentration threshold for genital health is 0.17 mmol/l before calving, 0.35 mmol/L 3-14 days after calving. For BHB, the genital health threshold is 1.1 mmol/l (Dubuc et al, 2010).

At 21-35 d after calving, BCS and vaginal content were collected. Endometrial and cervical smears were performed (cells being collected with a cytobrush). After smear staining (555 staining, RAL, Libourne, France), the proportion of neutrophils >200 cells was counted. Cows with more than 6% neutrophils on uterine smears were considered affected by endometritis, whereas those with more than 5% on cervical smears were defined as a cervicitis. A cow was defined affected by genital inflammation when the uterus and/or the cervix was found inflamed.

Results: Prevalence of cytological cervicitis was 23%, and 47% for endometritis. In total, 53% of the cows were affected by genital inflammation, but only 17% had both compartments simultaneously inflamed. Median body condition score was 3.5 [2.5-4.5] [min-max] before calving, 2.75 [2-4] at 3-14 days after calving and 2.5 [1.5-3.5] at 21-35 days after calving. NEFA blood concentration was above threshold in 40% of the cows before calving and in 50% of the cows at 3-14 days after calving. BHB was above the threshold in 51% of the cows.

No correlation was found between the proportion of cervical or uterine neutrophils and any risk factor tested (BCS before and after calving, BCS variation, NEFA concentration after and after calving, variation in NEFA concentration, BHB concentration). From a qualitative point of view (cow affected or not), the presence of inflammation was not associated with any of the tested risk factors, neither for cervicitis, nor for endometritis or genital inflammation.

Conclusions: BCS, BHB and NEFA concentrations were not associated with the risk of cervical, uterine or genital inflammation and not linked

to inflammation severity. Our results suggest the impairment of reproduction associated with negative energy balance is not mediated by an inadequate uterine microenvironment. One alternative hypothesis is the alteration of oocyte quality.

At the herd level, showing negative energy balance allows to correct transition feeding; when a cow is identified as having a severe negative energy balance, further research is needed to evaluate the impact of a corrective supplementation (e.g. propylene glycol) on reproduction.

Leptine, Transferrine and α 1-Acid glycoprotein correlations in goats fed with different fat sources and submitted to laparoscopic ovum pick-up

Ricardo P. Nociti¹ Priscila Silva¹ Ricardo R. Uscategui¹ Luciana P. Nakaghi¹ Felipe Barros¹ Guilherme A. Motta¹ Renata S. G. Mariano¹ Leandro N. Coutinho¹ Victor C. Santos¹ Marcus A. R. Feliciano¹ Wilter R. R. Vicente¹ Maria Emilia F. Oliveira¹ José J. Fagliari¹ Vera Hossepian¹

¹Universidade Estadual Paulista Júlio de Mesquita Filho, Jaboticabal, Brazil

Objectives: The aim of the present study was evaluate the acute phase proteins (APP) profile and their correlation with plasma leptin levels in eighteen goats fed with different fat sources and submitted to twice-laparoscopic ovum pick-up (LOPU).

Materials and Methods: Eighteen Anglo-Nubian goats were randomly divided into 3 groups based on their diets with different fat sources [soy oil (S, n=6), linseed (L, n=6) and Megalac® (M, n=6)], formulated with 40% concentrate, 60% corn silage and 4% ether extract (in dry matter) from the fat source. The animals were submitted to 15 days adaptation period and, then, an experimental period of 77 days. The LOPU was performed after 36 hours of an ovarian superstimulation protocol [FSH (80mg) + eCG (300IU)], on Day 42 (LOPU1) and Day 70 (LOPU2) of the trial. The blood samples were taken just before each LOPU (D42 and D70), 24 hours (D43 and D71), and seven days (D77) after the second LOPU. The fraction of proteins were obtained by SDS-PAGE and leptin levels were obtained by radio immune assay. Data were analyzed by ANOVA for repeated measures with Tukey post-hoc test ($p \leq 0.05$) and the correlations by Pearson correlation test using software R. There were no interaction between groups and time; furthermore, the results are expressed in principal components by means \pm sd with capitl letters denoting statistical difference.

Results: Were found between 16 to 18 proteins and for this study transferrine (TRANS, mg/dL) and α 1-Acid glycoprotein (α 1-AGP, mg/dL) were elected as relevant. Leptine was similar between groups (S (2.02 \pm 0.83), L (1.85 \pm 0.96), M (2.21 \pm 0.84)) and the mean of D42, D43, D70, D71 and D77 are 1.92 \pm 0.78ABC; 1.86 \pm 0.86BC; 1.54 \pm 0.55C; 2.28 \pm 0.77AB; 2.53 \pm 1.13A. TRANS means between groups are S (467.87 \pm 184.50); L (600.61 \pm 139.23) and M (548.93 \pm 171.62) and the mean of D42, D43, D70, D71 and D77 are respectively 489.06 \pm 176.91B; 476.88 \pm 127.5B; 574.83 \pm 202.49AB; 527.53 \pm 194.22AB and 627.38 \pm 119.95A. α 1-AGP means between groups are S (47.17 \pm 28.90); L (54.95 \pm 30.31) and M (53.09 \pm 33.52) and the mean of D42, D43, D70, D71 and D77 are respectively 54.71 \pm 38.53 ; 46.39 \pm 24.50; 53.48 \pm 31.69; 57.12 \pm 35.80 and 46.96 \pm 22.35. Both TRANS and α 1-AGP were positively correlated with leptine (R=0.32, $p=0.002$ and R=0.21, $p=0.04$; respectively) and positively correlatated with each other (R=0.28, $p=0.006$). TRANS and α 1-AGP was similar between groups and only TRANS demonstrate

moment effect with highest value of TRANS detected on D77 and the lowest on D43. TRANS is related with iron metabolism and a negative APP (decrease the serum values when a inflammatory process installs) in this study were noticed that serum levels of TRANS increased seven days after the second LOPU (D77). The lowest value of leptine were detected on D70 and highest on D77 (similar to TRANS).

Conclusions: According to these results Leptine, TRANS and α 1-AGP were not affected by fat source; despite what was reported in monogastric animals and humans the enrichment with polyunsaturated fat acids(PUFA). Leptine can be described as an adipocyte-derived cytokine and our results shows a low correlation with TRANS and α 1-AGP that should be more investigated.

The effects of varying levels of dietary starch on reproductive traits in lactating dairy cows

Abdulkadir Keskin ¹Hidir Gençoğlu ²Gulnaz Mecitoglu ¹Ismail Cetin ²Cagdas Kara ²Duygu U. Kucuksen ³Baris Guner ¹Abdulkadir Orman ⁴Merve Efil ²Ahmet Gumen ^{1*}

¹Department of Obstetrics and Gynecology, ²Department of Animal Nutrition and Nutritional Disease, ³Department of Biochemistry, ⁴Department of Zootechnics, ULUDAG UNIVERSITY, Gorukle Kampusu, 16059 Bursa, Turkey

Objectives: The aim of this study was to determine the effects of different dietary starch levels on a) postpartum ovarian follicular development, b) first postpartum ovulation day, c) involution of the genital tract, d) ovulation time and ovulatory follicle size after induced estrus, e) luteal size after ovulation, and f) the increase in progesterone levels 7 d after ovulation.

Materials and Methods: A total of 23 primiparous Holstein - Friesian cows were used in this study. They were fed three different diets that included different starch levels in milk on a dry matter basis from parturition until 80 d. Cows were randomly assigned into the three groups according to the starch levels of the diets: low (16%, LS group, n = 7), medium (20%, MS group, n = 8), and high (24%, HS group, n = 8). Milk yields were recorded daily, and body conditions (BCS) were scored every week. Transrectal ultrasonography was performed, and blood samples were taken three times each week to determine reproductive traits and blood metabolites.

Results: Although the milk yield was greater in the LS group compared to the other groups, BCS and blood metabolites did not differ between the groups. The mean size of the largest follicle during the first week postpartum (6 ± 1 d postpartum) was 9.6 ± 0.5 mm; this did not differ significantly (P > 0.05) among the groups. The times to the emergence of the first follicular wave after parturition (8.83 ± 1.0 d, 9.37 ± 0.95 d and 10.12 ± 0.95 d in the LS, MS, and HS groups, respectively) did not differ significantly (P > 0.05) between the groups. The postpartum follicular patterns, times of first postpartum ovulation, and involution processes did not differ among the groups. In addition, the ovulatory follicle and corpus luteum sizes and the progesterone levels after induced estrus were found to be numerically greater in cows fed with high starch levels than in other cows.

Conclusions: In this study, different dietary starch levels did not affect blood metabolites or early or late postpartum reproductive traits. However, milk yield was found to be higher in the LS group than in other groups

Equine Chorionic Gonadotropin Use in Fixed-Time Artificial Insemination Protocols in Non-Cyclic Cows

Ana Cristina Silva de Figueiredo ¹Carlos Antônio de Carvalho Fernandes ²Henderson Ayres ³João Paulo Barbuio ³Rafael Marin Chiummo ³Denis Barbosa Alves Antonio ³

¹Animal Reproduction, University of Alfenas, and Biotran LTDA, ²Animal Reproduction, University of Alfenas and Biotran LTDA, Alfenas, ³MSD Animal Health, Sao Paulo, Brazil

Objectives: In Brazil, about 11% of the 65.5 million female cattle, eligible for breeding, are artificially inseminated. 70% of them have zebu genetics and are beef breeds. Usually, estrus detection is difficult and zebu females show a long postpartum anestrus. Beef cattle are raised extensively, making conventional insemination impossible. Hormonal protocols allowing Fixed-Time Artificial Insemination (FTAI), even in acyclic cows, have widely spread. The purpose of this study was to determine the efficacy of equine Chorionic Gonadotropin (eCG) in accelerating follicular growth rate, and in improving ovulation rate in a FTAI protocol in acyclic cows.

Materials and Methods: Forty crossbred cows were used (20 cows and 20 heifers) with an absence of a corpus luteum and the presence of at least one ≥7mm diameter follicle. The animals were submitted to the following protocol: D0: placing a progesterone implant and application of 2 mg estradiol benzoate; D8: removal of the implant and IM application of 0.5mg sodium cloprostenol (Ciosin® MSD Saúde Animal - Brazil). On this day, the ovaries were evaluated and the diameter of the largest follicle was measured. According to the diameter, females were divided evenly into two treatments, via IM, in D8 yet. T1 (n=20): 300 IU of eCG (Folligon® - MSD Animal Health - Brazil) T2 (n=20): 1.5 mL of saline. On D9, all animals received 1 mg of estradiol benzoate, via IM. Ultrasound was used (Mindray-M5) with 7.5 Mhz linear transducer for ovaries evaluation. Tests for detecting the largest follicle diameter were performed from D8 to D10 every 24 hours. From D11 to D12 the ovulation was observed, which was confirmed on D17. The average follicular diameter of each treatment on each day was compared by the Tukey test. The percentage of ovulation were compared using Fisher's exact test. Probability lower than 5% was considered significant. For analyzes it was used the SAS software version 9.3.

Results: In both categories alone (cows and heifers) and in all females together there were no differences (P>0.05) in the average follicular diameter at D8, i.e. on the day the animals were distributed within their treatments. This lack of difference shows that the animals were equally randomized in treatments and there was no effect of follicular size prior to the treatment. There was an increase in the rate of follicular development in animals treated with Folligon®. In cows under this treatment, the follicular development was faster, showing the tested product activity. The mean follicular diameter was as follows. D8: 8.9+2.3 vs. 9.0+3.1; D9: 10.0+3.7 vs. 9.2+3.4; D10: 11.0+2.7 vs. 9.1+4.1 for T1 and T2, respectively. In D9, 24 hours after product administration, there was a difference trend (P=0.09) among the average diameter. The next day, i.e., D10, the difference between treatments was significant (P<0.05). The percentage of cows that ovulated at the end of protocol between D11 and D12 was higher than T1 (95.0 vs. 30.0% - P<0.05). The number of females in this treatment that exhibited corpus luteum in D17 was higher (90.0 vs. 30.0% - P<0.05).

Conclusions: The conclusion of this study was that the use of equine Chorionic Gonadotropin accelerates follicular development and improves the ovulation rate in Fixed-Time Artificial Insemination protocols in acyclic cows.

P02-002-183

Incidence of luteal phase inseminations and fertility rates in indigenous Nigerian Bunaji cowsHassan Mai^{1,*} Ambose A. Voh² Mohammed Sanusi¹¹Animal Production, Abubakar Tafawa Balewa University, Bauchi, Nigeria, Bauchi, ²Artificial Insemination Unit, National Animal Production Research Institute ABU, Shika-Zaria, Nigeria

Objectives: There is a paucity of information on the extent to which Nigerian indigenous cows are inseminated when they are not in oestrus, resulting in dwindling conception rates. The present study was undertaken to investigate the incidence of luteal phase inseminations and fertility rates in artificially inseminated Nigerian Bunaji cows.

Materials and Methods: A total of 269 normally cycling Bunaji cows aged between 4 and 9 years were used for this study. Double injection of 25mg Prostaglandin F₂α (PGF₂α) analogue (Lutalyse® Upjohn Co. MI) at 13 days interval was used to synchronize oestrus (Voh, Jr. et al. 2004). Visual oestrus detection and oestrus detection aids, namely tail-painting, KaMar heat mount detectors and vasectomized bull harnessed with a chin-ball mating device were all applied at the time of second PGF₂α injection (Mai et al., 2002). Both natural and induced oestruses were studied. Peripheral serum progesterone concentrations (SPC) at insemination and day 21 post-insemination were determined by a solid phase non-extraction I¹²⁵-Radio immunoassay method. The SPC at insemination was used to determine LPI. Cows with P₄ levels equal to or greater than 1.0ng/ml were considered to be in the luteal phase during AI hence the insemination considered to be a LPI (Coppens et al., 1987). Pregnancy was determined by SPC at day 21 after insemination and confirmed by rectal palpation 35 – 40 days post-insemination.

Results: The results revealed that out of the 560 inseminations carried out, the incidence of luteal phase inseminations (LPI) was 126 (22.5%). Variations in the post-service interval spanned between 4 and 57 days. The oestrus detection rate (70%), overall conception rate (32.0%), first service conception rate (51.6%) and number of services per conception (3.13) were considered unsatisfactory. Five cows conceived to the luteal phase insemination. The interval from one oestrus to another oestrus exhibited or incorrectly identified during the luteal phase (LPI) ranged from 27 to 39 days. Those cows inseminated in the luteal phase returned to oestrus between 4 and 15 days period. However, cows that failed to conceive in the same group, in spite of detection of oestrus and AI, manifested oestrus 18 to 57 days later.

Conclusions: Some of the factors likely to be responsible for the LPI include "Phantom heat" and management errors in heat detection on the part of the herdsmen, incorrect identification of animals, breakdown in communication between farm staff and inseminator or inadequately marked cows where heat detection aids were used. The results of the study have confirmed the incidence of LPI in Bunaji cows and this may contribute to the reduced conception rates observed in AI programmes in Nigeria.

Investigation on mortality caused by calving disorders in cowsGiuseppe Martano^{1,*}¹Veterinary Service, ASL TO3, Vigone (TO), Italy

Objectives: the objective of this work was to evaluate the mortality prevalence due to calving disorders in bovine. there are several common problems that affect cows during calving: dystocia, laceration, rupture, uterine prolapses, retained placenta, which pose a great threat to production and reproduction efficiency of animals. In this study we considered two breeds : the Holstein and the Piemontese (an local italian breed).

Materials and Methods: We have studied a sample of 290 bovine herds located in northwest Italy. In these farms were raised 25800 bovine of different breeds. The length of this study was twelve months, from January to December and particularly they were examined calving data about 5629 holstein cows and 5410 Piemontese breeds cows. During the period under study were registered 4503 calvings in the Holstein cows and 4320 calvings in Piemontese breed cows. We collected data about age, breed, feeding, possibility of moving, management, staff experience.

Results: In this study we recorded 37 deaths caused by calving disorders in Holstein cows and 29 in Piemontese cows and we have examined data about age, breed, feeding and management. The mortality rate due by calving disorders was respectively 0,82 % in Holstein and 0,67 % in Piemontese cows. The risk of dystocia increased parity in Holstein and decreased in Piemontese breed. We have not found significant differences about season and feeding. We have found that a factor which was most decisive was the degree of readiness of farmer staff.

Conclusions: Risk factors for calving related disorders for dairy and breeding cows could be multiple and various. The relatively high mortality during calving found in this survey suggests a increased care in herd's management. The highest mortality rate was recorded in poorly managed herds.

Use of Different Protocols Combining GnRH and Prostaglandin Analogues for the Treatment of Ovarian Cysts in Dairy CowsAna Cristina Figueiredo^{1,*} Carlos Fernandes^{1,2} Joao Henrique Viana³ Mauricio R. Vieira⁴ Denis A. Antonio⁵ Henderson Ayres⁵ Joao Paulo Barbuio⁵¹Animal Reproduction, Biotran LTDA, ²Animal Reproduction, University of Alfenas, Alfenas, ³Animal Reproduction, Embrapa - Dairy Cattle, Juiz de Fora, ⁴Animal Reproduction, Consulte Consultoria, Governador Valadares, ⁵MSD Saúde Animal, São Paulo, Brazil

Objectives: Ovarian cysts are a frequent pathological condition in dairy cattle Two types of ovarian cysts were described, follicular and luteinized. As the degree of luteinization of ovarian cysts is variable, adding prostaglandin F₂α to GnRH treatment may results in better

treatment outcomes than GnRH treatment alone. The aims of this study were to determine the incidence of follicular and luteal cysts in dairy herds in Southwest Brazil, and to evaluate the effectiveness of different treatment protocols using a GnRH combined or not with prostaglandin F2alpha.

Materials and Methods: Holstein cows (N=1,100) from four dairy farms located in the Minas Gerais State, Brazil, were evaluated in the post-partum period (days 28 to 40 days) by ultrasonography (Mindray M5, Mindray, SP, Brazil; linear 7.5MHz transducer) to detect ovarian cysts, characterized as anechoic structures 20 mm or greater in diameter. The cysts with a thin wall were classified as follicular, while those with the presence of a thick wall with the characteristic echotexture of luteal tissue were classified as luteinized. The cows previously diagnosed as bearing follicular or luteinized ovarian cysts were allocated into five groups, balanced according the type of cysts and days post-partum: G1 (Control Group; n = 16), 2 mL of saline; G2 (n = 31), 0.5 mg of Gonadorelin (GO) (Fertagyl™ MSD Saúde Animal, São Paulo, Brazil); G3 (n = 28), 0.5 mg of GO and 0.53mg Sodium cloprostenol (SC) (Ciosin™ MSD Saúde Animal, São Paulo, Brazil) 10 days later; G4 (n = 29) 0.5mg GO and 0.53mg SC given at the same moment; and G5 (n = 32), 0.5mg GO and two SC (0.53mg) shots, the first given at the same moment of GO and the second one 10 days later. All treatments were injected im. All treated cows were re-evaluated between 7 and 10 days after the end of each treatment. The continuous value parameters were assessed for normality, evaluated by ANOVA, and differences among treatments compared with Tukey's test (SAS Software, version 9.3). Differences in the efficiency of treatments were compared by the Chi-squared method. A p-value of 0.05 indicated statistical significance.

Results: Treatment was defined as effective if, at 7-10 days after treatment, the ovarian cyst had disappeared and a corpus luteum had developed. There was no farm effect ($P>0.05$). Ovarian cysts were detected in 12.4% (136/1100) of the cows, from which 23.5% (32/136) were classified as luteinized. The effectiveness of the treatments were differed between groups (18.75%^a, 54.8%^b, 53.5%^b, 79.3%^c, and 81.3%^c, for G1, G2, G3, G4, and G5, respectively; $P<0.05$). The best treatments were those who initially using PGF and GnRH (G4 and G5). The interval treatment to the first service (61.2±17.9^a, 44.5±16.4^b, 30.9±12.6^c, 26.19±14.3^c and 18.3±10.2^d days) and treatment to conception (71.9±21.9^a, 60.8±19.4^b, 48.3±16.9^c, 46.1±15.6^c, and 35.1±14.3^d days for G1, G2, G3, G4, and G5; respectively) differed between groups ($P<0.05$). However, there was no difference in conception rates among groups ($P>0.05$). The use of SC in the beginning of the protocol resulted in the higher effectiveness of treatment in groups G4 and G5, probably because of its effects in luteinized cysts. Considering cows with only luteinized cysts the efficiency was 33.3^a, 42.9^a, 50.0^a, 87.5^b and 87.5^b – $P>0.05$, for G1, G2, G3, G4 and G5, respectively. However, when a second SC was included in the protocol (G5) there was a further reduction in the interval from treatment to conception, when compared to G4. This reduction occurred probably because the second SC injection promoted the lysis of corpora lutea eventually formed after the earlier GO injection.

Conclusions: The incidence of ovarian cysts in the 4 study herds is 12.4%. Combined treatment of ovarian cysts with cloprostenol and gonadorelin is effective especially if it is followed by a second cloprostenol injection 10 days later.

Estimating of Weight from the Coronet Width of the Bovine Fetus before Delivery by Ultrasound Images

Honami Tasaki¹·Chikako Tani²Sayuri Harumoto³Koichiro Hemmi⁴Yasuo Moritomo³Hiroomu Katamoto⁴Takeshi Osawa⁴Mineto Tani³

¹Tokai University, Nagasaki, ²University of Miyazaki, ³Tokai University, Kumamoto, ⁴University of Miyazaki, Miyazaki, Japan

Objectives: Dystocia is defined as delayed or difficult parturition. General causes are fetal-maternal size mismatch, fetal malpresentation and maternal-related causes such as uterine torsion. In particular, an excessive fetus causes a dangerous condition for both a cow and a calf. The size of the fetus has been estimated from the size of the hoof by rectal examination in clinical practice. However, this method was not effective due to lack of accuracy. The purpose of this study was to estimate the weight from the coronet width (hoof width) of the fetus just before delivery by ultrasound images.

Materials and Methods: A total of 78 calves, Jersey(male 12 female 6), Japanese Brown(male 12 female 8), Japanese Black(male 2 female 2) and Holstein (male 19 female 17), was used from 2013 to 2015. Experiment A: Measurement of the hoof crown width of fetal forelimb coronet width (hoof width) was measured using an ultrasonography (linear type 6-10MHz, Ezaote Inc.) per rectum from 10 days before the expected date of delivery. Gestation period of dairy and beef cattle were 280 and 285 days, respectively. Experiment B: The relationship between the hoof width and the body weight was measured by using an ultrasonography (the water immersion method: echo value) and a caliper (measured value) within 24 hours after delivery. Body weight of calves it was measured with a digital scale. (Minimum measured quantity: 50g). We have calculated the relationship between the hoof width (Echo value-measured value) and weight. It was applied to actual cases.

Results: Experiment A: The hoof width of the fetus was measured from the ultrasound image of the middle phalanx distal cross-section. Experiment B: Jersey, Holstein, Japanese brown cattle, Japanese black cattle of gestation days (mean ± SD) was 282.1 ± 4.5, 276.0 ± 5.4, 284.3 ± 3.8, 290.8 ± 2.6, each body weight (kg) was 28.4 ± 4.0, 40.0 ± 5.1, 34.6 ± 4.8, 27.3 ± 3.6, and each hoof width measured value (mm) was 53.9 ± 2.2, 57.4 ± 2.8, 56.7 ± 3.3, 52.0 ± 3.0, respectively. The relationship between the hoof width (Measured value) and hoof width (echo value) was $Y = 0.9933X + 1.1124$ ($R^2 = 0.9574$, $P < 0.001$). The relationship between the measured value of the hoof width [X] and the weight [Y] is, Holstein: $Y = 1.444X - 42.907$ ($R^2 = 0.627$, $P < 0.001$), Japanese brown cattle: $Y = 1.353X - 42.110$ ($R^2 = 0.860$, $P < 0.001$). By measuring the hoof width of fetus using ultrasonography, it was found to be about the same as the measured value. If the fetal weight would be estimated before birth using this formula, it is possible to treat to avoid dystocia. Exactly using the weight estimation for excessive fetal of Japanese brown cattle, it was found that this way was useful method. We want to strive to applications in calving management practices by increasing the number of examples.

Conclusions: The hoof width of the fetus could be accurately measured by ultrasound imaging. Strong correlation was observed between the hoof width and weight of the calf. This study suggested that it is possible to estimate the weight of the fetus by measuring the hoof width of the fetus in the ultrasound image.

The effect of feed on the postpartum ovarian dynamics and the body condition score of grazing breeding beef cattle

Kyoko Kawakami¹ Chikako Tani² Saki Tanabe¹ Norifumi Hattori¹ Masahiro Saneda¹ Takeshi Yamanaka¹ Yasuo Moritomo¹ Hiromu Katamoto² Mineto Tani¹

¹Tokai university, Kumamoto, ²University of Miyazaki, Miyazaki, Japan

Objectives: In previous studies, we reported that cows calving in January and February, compared with those calving in March and April, experienced delays in the recovery of their body condition score (BCS) and the start of their first ovulation after giving birth. These studies suggested the importance of energy intake before parturition in order to improve reproductive performance. The purpose of this study was to clarify if feeding supplementary concentrations to pregnant cows before calving would have an effect on their first ovulation and their body condition score (BCS) after parturition.

Materials and Methods: The Aso region is a highland (altitude 500 to 800m) located in the warm southwestern region of Japan but is relatively cool even in the summer. The average temperatures in February, March and April are 2.9 °C, 7.7 °C and 11.4 °C, respectively. The majority of Japanese beef cattle give birth seasonally, primarily in the spring, and breed in a pasture-based system in the Aso region. The study was conducted on 32 cattle (28 Japanese brown and 4 Japanese black) grazing on natural pastureland within Tokai University. Cattle were divided into the following 4 groups: W1, W2, S1 and S2 (W1: n=9, calving in 2012-2014. W2: n=5, calving in 2015. S1: n=14, calving in 2012-2014. S2: n=4, calving in 2015). W1 and W2 groups were delivered in January and February. S1 and S2 groups were delivered in March and April. Cows were kept in free grazing in grassland from April to October, eating about 10kg per head per day, and then in restricted feeding of 8kg per head per day of DMI grass silage from November to March. W2 and S2 were fed the supplementary concentrates from January to March. The ovaries and uterus were monitored by rectal palpation and ultrasonography from parturition to the next pregnancy; at 2 to 14 day intervals between January and August from 2012 to 2015. Evaluation of BCS using a 5-point scale with quarter-point divisions (Ferguson, 1994) was performed until confirmation of pregnancy.

Results: Feeding period (days, mean ± SD) of supplementary concentrates in W2 and S2 was 25.0±5.6 and 66.0±17.9, respectively. First ovulation days in postpartum in W1, S1, W2 and S2 was 67.4±16.1, 51.2±17.1, 63.0±17.3 and 34.3±11.5, respectively. The first ovulation of S2 was earlier than W1 (P<0.05). The BCS of S2 (3.25 ± 0.20) was higher than W1 (2.58 ± 0.35) and S1 (2.43 ± 0.36) at the time of delivery (P<0.05). It is thought that the lower BCS in the W2 group before and after parturition was due to a shorter feeding period of the supplementary concentrates. It is thought that ovulation could occur soon and the loss of BCS could be prevented in the W2 group if they are given the supplementary concentrates 2 months prior to delivery, as with the S2 group. The BCS of S2 (3.13 ± 0.14) was also higher than W1 (2.33 ± 0.28), S1 (2.46 ± 0.36), and W2 (2.40 ± 0.29) at the time of first ovulation (P<0.05), and was maintained the same level before and after parturition.

Conclusions: For preventing the loss of BCS, it was suggested that it would be effective to add supplementary concentrates from 2 months pre-birth. The present study indicated that it was important to prevent the loss of BCS before calving in reproductive management. In the future, it is necessary to examine the feeding amount and period of the supplementary concentrates.

The Effects of Salpingitis on Bovine Reproductive Success - New Concepts As Seen by Live Cell Imaging

Sabine Koelle¹ Deirdre Scully¹ Itagar Eseoghene¹

¹University College Dublin, Dublin, Ireland

Objectives: According to our studies, 30 -50 % of the cows slaughtered in European abattoirs reveal salpingitis. Inflammation of the oviduct is often associated with endometritis, but may also occur independently. As seen in our previous studies, salpingitis is a major cause for subfertility and idiopathic infertility. Therefore the aim of this study was to elucidate the effects of inflammation on sperm transport, sperm-oviduct interaction, oocyte transport, fertilization and early embryogenesis under near in vivo conditions.

Materials and Methods: For this purpose, oviducts revealing mild (n=35), moderate (n=30) and severe (n=22) inflammation were removed from cows immediately after slaughter. Oviducts with mild inflammation did not reveal macroscopic alterations, but showed increased vascularization in the stereomicroscopic investigation and an increased number of lymphocytes in the histomorphological analysis. Moderate inflammation was diagnosed by macroscopically visible increased vascularization whereas severe inflammation was associated with reddening of the tissue and visible amounts of secretion in the tubal lumen. Using a digital videomicroscopic live cell analysis system, which allows quantitative and qualitative assessment in real-time and under near in vivo conditions, the following parameters were investigated in the inflamed oviduct as compared to controls: a) mechanisms of transport of the oocyte and embryo, b) sperm-oviduct interaction and formation of the sperm reservoir, c) hyperactivation and detachment of sperm in the presence of the oocyte and d) fertilization and early embryogenesis. In addition to that, tissue samples with sperm and oocytes inside were analysed by stereomicroscopy, light microscopy, scanning electron microscopy and histochemistry.

Results: Our morphological investigations showed that inflammation in the oviduct was always correlated with increased numbers of lymphocytes being present in the epithelium and in the connective tissue. In addition to that, the capillaries in the mucosa were dilated and enlarged and increased secretory activity of the epithelium with accumulations of glycoproteins in the tubal lumen was seen. In severe inflammation, additionally increased apoptosis of the epithelial cells, loss of tight junctions, and shedding of epithelial cells into the lumen embedded in clumps of mucus were found. Live cell imaging revealed that particle transport speed (PTS) was significantly reduced resulting in retarded transport of the oocyte and the early embryo. Additionally ciliary beat frequency was decreased. In two individuals with moderate inflammation, cilia were immotile in specific regions of the epithelial folds. Accumulation of mucus resulted in sticking of the fertilized oocyte to the ampullar epithelium impairing timely transport of the early embryo in the oviduct. When huge accumulations of secretions were present sperm were stuck preventing them to form a sperm reservoir resulting in the loss of fertilizing capacity.

Conclusions: Our results imply that inflammation of the oviduct has a major negative impact on bovine reproductive success by compromising oocyte and embryo transport and by reducing survival time and fertilizing capacity of sperm. Thus, new diagnostic strategies such as the validation of a glycoprotein biomarker for salpingitis have to be developed. Furthermore new therapeutic concepts focusing on specific treatment of the oviduct, which aim to decrease secretory hyperactivity, would enable to further increase success rates of artificial insemination.

Serum paraoxonase-1 activity and nonesterified fatty acid concentration in relation to the resumption of ovarian activity in postpartum dairy cows

Ivan Folnožić¹ Marko Samardžija¹ Dražen Đuričić² Zlata Flegar-Meštrić³ Silvijo Vince¹ Romana Turk^{4,*}

¹Clinic for Obstetrics and Reproduction, Faculty of Veterinary Medicine University of Zagreb, Zagreb, ²Veterinary Practice Đurđevac, Đurđevac, ³Department of Medical Biochemistry and Laboratory Medicine, Merkur University Hospital, Zagreb, ⁴Department of Pathophysiology, Faculty of Veterinary Medicine University of Zagreb, Zagreb, Croatia

Objectives: The resumption of ovarian activity after calving is closely related to the severity of negative energy balance (NEB) and inflammatory response in the early lactation of dairy cows. Thus, the aim of the study was to evaluate nonesterified fatty acids (NEFA) concentration and paraoxonase-1 (PON1) activity related to the resumption of ovarian activity in postpartum dairy cows.

Materials and Methods: A total of 24 Holstein dairy cows were included in the study. The cows were assigned into two groups according to gynecological examination (rectal palpation and ultrasound examination) and progesterone (P₄) concentration: (1) ovulatory cows (n=11) which resumed ovarian activity within 60 days after calving; and (2) anovulatory cows (n=13) which did not resume ovarian activity during the same period. Blood samples were taken on days 5, 12, 19, 26 and 60 postpartum. Serum P₄ was measured by the immunoassay on Immulite 2000 analyzer (Siemens Healthcare Diagnostics, Germany); NEFA concentration was measured by Randox NEFA kit on biochemical analyzer SABA 18 (AMS, Rome, Italy) while high-density lipoprotein-cholesterol (HDL-C) concentration was assayed by the method based on selective inhibition of the non-HDL fractions by means of polyanions on Beckman Coulter AU 680 (Beckman Coulter Biomedical Ltd., Ireland). The PON1 activity was measured by the spectrophotometric assay using paraoxon as a substrate on Beckman Coulter AU 680. Statistical analysis was performed by SAS 9.3 Software. Results are shown as least squared means with 95% confidence interval.

Results: Serum NEFA concentration was significantly higher (P<0.05) in anovulatory cows postpartum (0.7 mmol/L) in comparison to the cows which resumed their ovarian activity within 60 days after calving (0.48 mmol/L). Anovulatory cows had significantly lower (P<0.05) PON1 activity after calving (228 U/L) than cows which resumed the ovarian activity postpartum (339 U/L). Accordingly, HDL-C concentration was significantly lower (P<0.05) in anovulatory cows after calving (1.8 mmol/L) compared to the cows which resumed the ovarian activity within 60 days postpartum (2.7 mmol/L).

Conclusions: Lower PON1 activity and higher NEFA concentration in anovulatory cows could indicate oxidative stress and inflammatory responses presenting a higher risk for decreased ovarian activity and thus lower reproductive efficiency of dairy cows after calving. Since serum PON1 is associated to HDL particle, lower HDL-C level in anovulatory cows might suggest the remodeling of HDL particle due to oxidative stress and inflammation. However, further studies are needed to elucidate the roles of PON1 and NEFA in decreased ovarian activity in postpartum dairy cows.

Survey on impact and effect of Caesarian section on postpartum fertility in Piedmontese beef cattle

Alessandro Ricci^{1,*} Matteo Gastaut¹ Marco Ribotta² Enrico Miglietti² Leila Vincenti¹

¹DPT Scienze Veterinarie, Università degli studi di Torino, ²Practitioner, Piemonte region, Italy, Grugliasco, Italy

Objectives: Piedmontese is a double muscle breed and then Cesarean section (C-section) is one of the most applied surgical techniques and is applied as routine field surgery, although complications during and after surgery are not unusual and should not be underestimated. This technique is believed to be associated with an increased risk of subsequent infertility and culling risk in cows. The objective of this study is to analyze indications and consequences of the C-section considering post surgery infections, therapy, resumption of ovarian cyclicity and partum to conception time.

Materials and Methods: Two skilled veterinary practitioners with homogeneous surgical protocols performed 174 C-sections on Piedmontese beef heifers and cattle, in 58 different farms, during a year of work. The data about farm, cause of the C-section, the surgical procedures, the subsequent pharmacological treatment were collected through within a few hours after surgery. As working procedure a check list of critical points was prepared in order to standardize the data collection. 154 cows were enrolled in the post surgical protocol and submitted to three or more postpartum clinical and ultrasound examination (1st visit 10-20 days/pp, 2nd visit 30-35 days/pp 3rd visit 90-100 days/pp, etc.) in order to collect all the information on post surgical complications and to evaluate the reproductive performances of cows.

Results: Collected data showed the incidence of different causes for surgery (calf macrosomia, 51.7%; dystocic parturition 16.1%; narrowness of the birth canal 10.9%). Partum season, geographical area and housing conditions have not affected post partum fertility (P>0.05). Neither suckling cows nor the presence of the calf twice a day show significant effect on fertility; all subjects showed resumption of ovarian cyclicity within 60 days postpartum (P<0.04). In accordance with the literature about beef cows these animals demonstrate partum to conception interval of 97 ± 30 days, compared with 157 ± 69 days of Friesian.

The differences in surgical protocol didn't affect the subsequent reproductive performances of cows, 62.3% subjects had a resumption ovarian cyclicity within 60 days postpartum, the 48.3% of cows conceive within 90 days postpartum and 82.8% within 120 days postpartum. The association of oxytetracycline hydrochloride systemic together with intrauterine administration greatly improves the reproductive performance in treated subjects, mainly in subjects with retained placenta, that show a resumption of ovarian cyclicity within 60 days post partum in a higher number of subjects (P = 0.03).

Conclusions: C-section has an average incidence of 10-15% within the Piedmontese cattle breed (heifers and cows) and is routinely applied on field with all the risks of an intervention carried out in non-sterile environment. Nevertheless a good practice, careful management and post surgery appropriate treatments are important to reduce detrimental effect on the reproductive career of submitted cows. Based on these considerations 88.5% of the cows undergoing cesarean section in this study have a chance to become pregnant within 120 days after surgery.

Testicular hemodynamic changes in ram according to the season of the yearMalgorzata Domino¹, K Borzyszkowski², Tomasz Jasinski³, Zdzislaw Gajewski¹¹Dep. of Animal Reprod, CBB, WCB, Warsaw University of Life Sciences, ²Dep. of Animal Reprod, CBB, WCB, Dep. of Animal reproduction, Warsaw University of Life Sciences, ³Dep. of Animal Reprod, CBB, WCB, FVM, WULS, Warsaw, Poland

Objectives: The numerous ram's reproductive parameters vary according to the season of the year. Nevertheless, the pattern of blood flow in the ram testis as well as the mean values for Doppler measures of blood flow in the testicular artery of the ram over the year were not yet to be estimated. The object of this study was to evaluate the testicular hemodynamic changes using pulsed wave Doppler sonography during and out of the breeding season.

Materials and Methods: Both testes from each of eighteen free of testicular pathology rams were examined using color and pulsed wave Doppler ultrasound with a linear array 3-13 MHz probe. Vessels of the epididymal edge of spermatic cord seen on two-dimensional ultrasound image were first detected with color Doppler and then blood flow of testicular artery was described with pulsed wave Doppler spectrum. Peak systolic velocity (PSV), end diastolic velocity (EDV), resistive index (RI), and pulsatility index (PI) of the testicular artery were measured in every examination both during and outside the breeding season.

Results: The parameters values (mean \pm SEM) were PSV (cm/s): 28.45 \pm 0.53, 33.78 \pm 1.24; EDV (cm/s): 7.96 \pm 0.26, 8.71 \pm 0.42; RI: 0.71 \pm 0.01, 0.71 \pm 0.01; PI: 11.38 \pm 0.37, 1.51 \pm 0.49 during and outside the breeding season respectively. We found that: (1) all measures were obtainable; (2) measures for left and right testes were comparable ($P > 0.10$); (3) PSV ($P < 0.0001$) as well as PI ($P = 0.039$) were statistically significantly higher out of the breeding season compared to breeding season; (4) there were no significant differences ($P > 0.05$) between EDV ($P = 0.165$) as well as RI ($P = 0.520$) measures during and outside the breeding season.

Conclusions: According to the season of the year, the differences in ram's testicular size, sperm production, and mating capacity have been reported, within significance increase during the normal fall breeding season. On the other hand significance decrease of blood flow in the testicular artery (PSV and PI) during breeding season were observed. Resulting measures from all free of testicular pathology rams may provide useful reference values for clinical evaluation.

Effect of shortening a synchronization protocol with a progesterone device (5d vs. 7d) for first AI in heifers on reproductive performance during the breeding seasonAlessio Valenza¹, E Hayes², K Timms³, A H Souza⁴¹Ceva Animal Health, Libourne, France, ²Synergy Farm Health, Evershot, ³Ceva Animal Health Ltd, Amersham, United Kingdom, ⁴University of California Co-operative Extension, Tulare CA, United States

Objectives: The objective of this study was to compare two different synchronization protocols for fixed timed-AI with a progesterone releasing intravaginal device (PRID 5d vs. PRID 7d) applied at the beginning of the breeding season on reproductive performance in Holstein dairy heifers.

Materials and Methods: A total of 434 New Zealand Friesian heifers, kept in 4 pasture based seasonal calving UK herds were randomized to receive two synchronization protocols for 1st AI: 1) PRID5d: D0-8:00 am = progesterone releasing intravaginal device (PRID[®] Delta, Ceva Animal Health) plus 100 mcg of GnRH (gonadorelin diacetate) i.m. (Ovarelin[®]/Cystoreline[®], Ceva Animal Health); D5-8:00 am = PRID[®] Delta removal and treatment with 25mg of PGF2a (dinoprost) i.m. (Enzaprost[®]T, Ceva Animal Health); D6-8:00 am = treatment with a second dose of 25mg of PGF2a i.m.; D8-8:00 am = 100 mcg of GnRH i.m. (Ovarelin[®]/Cystoreline[®], Ceva Animal Health) plus AI; and 2) PRID7d: D0-8:00 am = PRID[®] Delta; D6-8:00 am = treatment with 25mg of PGF2a (Enzaprost[®]T) i.m. ; D7-8:00 am = PRID[®] Delta removal; D9-4:00 pm = AI. After this first timed AI, heifers were placed on the same pasture with cleanup Holstein bulls in the estimated ratio of 1 bull to 25 non-pregnant heifers. Pregnancy diagnosis was performed by ultrasound at intervals of 30 days throughout the breeding season that lasted 12 weeks. Statistical analysis was performed with proc Glimmix and proc Lifetest of SAS.

Results: Overall, heifers that received the short synchronization protocol (PRID5d) for first AI had an increased proportion of pregnancies at week 3 (PRID5d = 69.9% vs. PRID7d = 57.8%; $P = 0.01$), 6 (PRID5d = 91.4% vs. PRID7d = 81.1%; $P = 0.10$), or 12 (PRID5d = 100.0% vs. PRID7d = 99.8%; $P > 0.10$) compare to the ones that received the standard synchronization protocol (PRID7d). The survival analysis indicated that heifers enrolled on the short progesterone-based timed AI protocol (PRID5d) attained the 75% pregnancy mark two weeks sooner than the ones receiving the 7 days progesterone-based protocol (PRID7d) during the breeding season.

Conclusions: In conclusion, heifers enrolled in the shorter progesterone-based timed AI protocol (PRID[®] Delta, Ceva Animal Health) for first artificial insemination (PRID5d) conceived faster during breeding season, anticipating calving and allowing heifers to start milking sooner.

Reproduction

P02-002-194

GnRH-induced LH profiles following Gonadorelin diacetate vs. Buserelin treatment in lactating dairy cows.Alessio Valenza¹, R Armengol-Gelonch², J M Mallo³, D Ponte², A Jimenez⁴, A H Souza⁵¹Ceva Animal Health, Libourne, France, ²Lleidavet, Lleida, Spain, ³Lleidavet, Lleida, , ⁴Ceva Salud Animal, A, , ⁵University of California Cooperative Extension, Tulare CA, United States

Objectives: The study was designed to characterize the GnRH-induced LH surge profile under high (Diestrus) or low (Pro-estrus) circulating progesterone in lactating dairy cows after treatment with two different types of GnRH products commonly used in breeding procedures of lactating dairy cows. The secondary objective was to investigate whether season (summer vs. winter) could alter LH surge profile.

Materials and Methods: Lactating Holstein cows at 108.2 \pm 2.3 days in milk (DIM), producing 41.5 \pm 0.3 kg/day were randomized to receive, during proestrus and diestrus (7 days after ovulation): 1)Cystoreline/Ovarelin[®] i.m. (n = 56; 2mL, 100 mg of Gonadorelin diacetate tetrahydrate;

Ceva Animal Health) or 2) Receptal® (n = 52; 2,5mL, 10 mcg of Buserelin diacetate; MSD). Data collection was done in two replicates (summer vs. winter) using different cows. Blood samples were collected at hour 0 (just before GnRH treatment), at 30min, 1h and then hourly until 5h post-GnRH treatment. Only cows having complete luteolysis (P4 1ng/mL) during diestrus were included in the analysis.

Results: Overall, There were no interactions between GnRH type and phase of the estrous cycle or season. Thus, peak LH concentrations (ng/mL) were not affected by type of GnRH (Cystoreline/Ovarelin® = 6.2±0.4 vs. Receptal® = 6.7±0.4; P=0.37) or season (winter = 6.8±0.4 vs. summer = 6.1±0.4; P=0.22), but were largely affected by phase of the cycle (proestrus = 8.2±0.4 vs. diestrus = 4.7±0.4; P

Conclusions: In conclusion, cows receiving Gonadorelin diacetate had greater circulating LH concentrations (ng/mL) at 1h after GnRH treatment than cows receiving Buserelin (4.2±0.3 vs. 3.1±0.3; P

¹Ceva Animal Health, Libourne, France, ²Department of Dairy Science, University of Wisconsin, Madison, ³Department of Dairy Science, University of Wisconsin, Madison, United States⁴Diessen Servicos Veterinarios Lda, Lisbon

Objectives: The objective of the study was to evaluate the effects of (1) decreasing the interval between the first GnRH (G1) and the PGF2 (PGF) treatment from 7 to 5 days, (2) adding a second PGF treatment 24 h after the first and (3) the degree of vaginal discharge at the time of the progesterone releasing intravaginal device (PRID® Delta, CEVA Animal Health) removal on P/AI during a resynchronization protocol for fixed timed artificial insemination (TAI) in lactating dairy cows.

Materials and Methods: Lactating Holstein cows (n = 821) were randomly assigned at a non pregnancy diagnosis (d 0) to one of three resynchronization protocols: 1) 7D1PGF: D0 = progesterone releasing intravaginal device (PRID® Delta) plus 100 mcg of GnRH (gonadorelin diacetate) i.m. (Ovarelin®/Cystoreline®, Ceva Animal Health); D7 = PRID® Delta removal and treatment with 25mg of PGF2 α (dinoprost) i.m. (Enzaprost®T, Ceva Animal Health); D9.5 = 100 mcg of GnRH i.m. (Ovarelin®/Cystoreline®); 2) 7D2PGF: D0 = PRID® Delta plus 100 mcg of GnRH (gonadorelin diacetate) i.m.; D=7 PRID® Delta removal and treatment with 25mg of PGF2α (dinoprost) i.m.; D8 = second PGF2α (dinoprost) treatment ; D9.5 = 100 mcg of GnRH (gonadorelin diacetate) i.m.; and 3) 5D2PGF: D2 = PRID® Delta plus 100 mcg of GnRH (gonadorelin diacetate); D=7 PRID® Delta removal and treatment with 25mg of PGF2α (dinoprost); D8 = second PGF2α (dinoprost) treatment ; D9.5 = 100 mcg of GnRH (gonaderlin diacetate) i.m. All cows received timed-AI approximately 16 h after the second GnRH treatment. The degree of vaginal discharge was evaluated at the time of PRID® Delta removal and blood samples were collected at the time of the last GnRH treatment and evaluated for progesterone concentrations. Pregnancy diagnosis was performed 32 ± 3 d and 60 ± 3 d after AI using a portable ultrasound scanner and statistical analysis was performed by logistic regression using the GLIMMIX procedure of SAS.

Results: Overall, cows receiving a second PGF2α treatment (7D2PGF + 5D2PGF) had more pregnancies per AI (P/AI) (42.6% vs. 35.7%) than cows receiving a single PGF2α treatment (7D1PGF). For cows treated with a second PGF2α treatment, decreasing the duration of the progesterone-based protocol did not increase P/AI (41.4% vs. 43.8% for 7D2PGF vs. 5D2PGF). In addition, neither the number of PGF2α treatments (8.5% vs. 10.6%, for 7D1PGF vs. 7D2PGF + 5D2PGF) nor the duration of the protocol (9.1% vs. 12.1%, for 7D2PGF vs. 5D2PGF) affected pregnancy loss from 32 to 60 d after TAI. The percentage of cows with incomplete luteal regression at the second GnRH treatment tended to be different among treatments and was least for 7D2PGF cows, intermediate for 5D2PGF cows and greatest for 7D1PGF cows (1.9% vs. 6.9% vs. 11.0%, respectively).

Conclusions: In conclusion, the addition of a second PGF treatment to a progesterone-based protocol increased the percentage of cows with complete luteal regression and P/AI (7D1PGF vs. 7D2PGF) and decreasing the interval between G1 and the PGF treatment from 7 to 5 days did not improve P/AI. The degree of vaginal discharge at the time of removal of the progesterone releasing intravaginal device (PRID® Delta, CEVA Santé Animale) did not affect P/AI.

Veterinary survey of the impacts of Mycotoxins in Cattle Food Production Systems

Katherine Lumb¹ on behalf of RAFT Solutions Ltd Jonathan Statham¹

¹RAFT Solutions Ltd, Ripon, United Kingdom

Objectives: This survey based review carried out as part of a collaborative AHDB supported project aimed to assess the impact of mycotoxin exposure on the livestock industry through collating information on the experiences of vets and farmers with mycotoxins. They were asked to comment on different clinical presentations seen, the uptake and benefits of available diagnostic services and methods used to mitigate mycotoxin exposure. They were also asked to evaluate their perceived significance of mycotoxins, their knowledge, the availability of scientific evidence and the routes of knowledge transfer within the industry.

Materials and Methods: The surveys were designed specifically for veterinary and farmer populations and included open and closed questions to provide consistency in results. Vets at Bishopton Veterinary Group, Synergy Farm Health and The University of Nottingham trialled the surveys to ensure an appropriate time frame was required to complete the survey and they were written in an appropriate manner. Paper and electronic copies of the surveys distributed through BCVA, PVS, SVS, BPEX and the XLVets network as well as directly to farmers from Bishopton Veterinary Group, North Yorkshire and Synergy Farm Health, Dorset. This aimed to improve compliance and increase responses by providing the most appropriate response form for different groups. It also tried to ensure that an appropriate geographical distribution was obtained to be representative and minimise bias. Surveys were however restricted geographically to the UK to comply with the project budget.

The surveys were split into sections to focus on;

Case experience and management. Including; clinical presentations, uptake and experience if diagnostic services, individual toxin identification

Mitigating practices. Including; rationale behind binder inclusion, time periods and duration of binder inclusion, observed responses and evidence to support binder inclusion, other recommended mitigating methods

Knowledge transfer. Including opinions on; significance of the impact of mycotoxins, availability of scientific evidence, level of knowledge, knowledge transfer streams.

Survey results were collected & analysed in Microsoft Excel.

Results: Responses demonstrated that vets had greater experience with mycotoxin exposure at both individual & herd level than farmers. Use of testing services was limited among vets (32%) & farmers (18%). Respondents reported sending forage/feed samples, blood, bile, tissue samples, gut contents & water. Aflatoxins were most commonly tested for in cattle (22%), but a limited number of respondents (17%) reported obtaining positive results.

A large proportion of vets clients (72%) & farmers (49%) were including mycotoxin binders, the majority (85%) in dairy herds. The most common rationale for inclusion was risk based, during the winter period/housing 17% or based on clinical presentation (15%). The most commonly reported method used to monitor binder inclusion response was the resolution of clinical signs. A large proportion of respondents (40%) reported seeing no response following inclusion & the most common rationale (60%) for this was that mycotoxins weren't the underlying problem. Hygiene of feed storage and ongoing monitoring of environmental conditions to limit the development of mycotoxins were the most commonly recommended mitigating practices.

The majority of vets & farmers were in agreement that they were unsure of the significance of the impact of mycotoxins on livestock production. Their opinions differed in the availability of scientific evidence. Vets perceived feed companies as the main route of knowledge transfer to farms, whereas farmers saw vets as the source. Overall farmers rated their knowledge of mycotoxins as average, vets rated their knowledge as poor.

Conclusions: The clinical signs observed by vets and farmers were similar but consistently vague and non-specific. The inclusion of mitigating products appears to be commonplace but it is often with little clinical or diagnostic evidence, and with limited positive responses. The results confirmed this, demonstrating limited uptake of testing services from both vets and farmers. The perceived lack of evidence available to vets, combined with farmer reliance on this knowledge transfer route highlights areas where more industry focus is required to encourage consistent knowledge transfer.

The Efficacy of a Single Dose of Equine Chorionic Gonadotropin for Superovulation of Cows

Carlos Antônio de Carvalho Fernandes¹; Ana Cristina Silva de Figueiredo¹; Henderson Ayres²; João Paulo Barbuio²; Rafael Marin Chiummo²; Denis Barbosa Alves Antonio²

¹Animal Reproduction, University of Alfenas and Biotran LTDA, Alfenas,

²MSD Animal Health, Sao Paulo, Brazil

Objectives: The Equine Chorionic Gonadotropin (eCG) is extracted from pregnant mares' serum. It is usually produced by the placenta of this species between 40 and 130 days of gestation. In bovines, it

can link to both FSH and LH receptors in the ovarian follicles. The main advantage of eCG is the induction of superovulation. Due to its extended half-life, we hypothesized eCG may need only one injection, without affecting efficacy, where other products need several applications to be effective. The objective was to verify the efficacy of one single dose of eCG (Folligon® MSD Animal Health - Brazil) for induction of super-ovulation of bovines.

Materials and Methods: Twenty cyclic crossbred females were used (10 cows and 10 heifers) randomly divided in crossover design. All females were submitted to two subsequent treatments that were repeated twice within a 40-day interval. The following protocol was used: D0: insertion of a progesterone implant plus application of 2mg estradiol benzoate; D4: 2,000IU (IM) of eCG (T1) or 10ml (IM) saline (T2); D8: removal of the implant and IM application of 0.5mg sodium cloprostenol (Ciosin® MSD Animal Health - Brazil); D9: IM application 0.1mg of Gonadorelin (Fertagyl® MSD Animal Health - Brazil). A Mindray M5 ultrasound 7.5 MHz linear transducer was used to evaluate the ovaries. Evaluations were carried out on D0 and from D4 to D9 on a daily basis. The number of ≥ 5 mm \emptyset follicles were counted during these evaluations. Another appraisal took place on D18 to determine the number of ovulations as per the number of corpora lutea. The animals were uniformly divided according to the number of ≥ 5 mm \emptyset follicles on D4 - prior to treatments of the first repetition. The data were submitted to a normality test and the mean number of ≥ 5 mm diameter follicles on each day of the evaluation was compared on D0 and from D4 to D9 using the Tukey's Test. On D17 the number of ovulations was also compared, using the Fisher's Exact Test. The significance level was considered as less than 5% probability and all statistical analysis were performed using the SAS program version 9.3.

Results: Cows and heifers data were analysed together (no category effect). On the randomization day, average number of follicles capable of responding to development stimulation (≥ 5 mm \emptyset) were unchanged (1.9 ± 0.8 and 2.1 ± 0.7 for T1 and T2, respectively - $P > 0.05$), showing females were uniformly distributed between treatments. No differences were observed of variables under control while comparing both repetitions ($P > 0.05$). The evolution of the number of ≥ 5 mm \emptyset follicles - considering both repetitions together - was as early as 24 h after application of eCG (D5), the number of follicles in T1 was $> T2$ ($P < 0.05$) - and was maintained until D9. The average number of ≥ 5 mm \emptyset follicles on different days for T1 and T2, was respectively: D5: 10.0 ± 5.2 vs. 4.6 ± 1.7 ; D6: 14.5 ± 6.6 vs. 2.3 ± 1.9 ; D7: 19.3 ± 7.1 vs. 2.3 ± 1.6 ; D8: 24.1 ± 8.9 vs. 2.8 ± 2.0 ; D9: 24.0 ± 8.3 vs. 2.3 ± 1.7 . In addition, a gradual evolution of the average number of ≤ 5 mm \emptyset follicles between D4-D8 of animals from T1 was seen, showing eCG is capable of stimulating new follicles development for a long period after application. In the control group, there was a reduction of the average count of follicles during certain periods. Control animals were in follicular dominance and had atresia in part of the existing population. As a result of the eCG stimulation at the beginning of the follicular wave, more follicles reached the protocol end (D9) presenting hormonal conditions to ovulate, i.e., with a \emptyset of ≥ 9 mm (16.7 ± 4.8 vs. 1.2 ± 0.6 - $P < 0.05$). The ovulation rate from T1 was higher (16.0 ± 5.8 vs. 0.9 ± 0.5 - $P < 0.05$) than the control group (T2).

Conclusions: The conclusion is that the product Folligon® - while using the application schema of one single dose of 2000 IU of eCG is effective in promoting greater follicular development and super-ovulation of cows.

The effect of natural and induced calving of beef heifers on maternal health and colostrum quality

Marijke Beltman¹ Miha Savc¹ David Kenny²¹University College Dublin, Dublin, ²Teagasc, Dunsany, Meath, Ireland

Objectives: The aim of this study was to determine the effect of natural and induced calving in continental cross beef heifers carrying pedigree Simmental calves on the subsequent cows' immune system, colostrum quality and subsequent reproductive health.

Materials and Methods: At day 285 of gestation, 55 crossbred recipient beef heifers carrying purebred Simmental embryos, were blocked by live-weight BCS, expected calving date and foetal gender and assigned to one of three groups: (i) control (no induction treatment; CON, n=19); (ii) induction with corticosteroids (CORT, n=20) and (iii) induction with corticosteroids plus prostaglandin (CORT+PG, n=16). Interval from induction to calving in hours and calving ease were recorded. Vaginal mucus samples were collected on day 21 (D21) and 42 (D42) post calving (D0) by means of a Metrichick® and scored on a scale of 0-3. Reproductive examinations were conducted on D21 and D42 days post calving and uterine cytology samples were obtained on D21. Blood samples were taken at 2 weeks before parturition (D-14), 1 day after parturition (D1) and 2 weeks after parturition (D14) for subsequent analysis of cortisol and calcium (Ca) concentrations. Calves were weighed at birth and subsequently every week until 10 weeks of age and a colostrum sample was taken immediately after the calving and stored for subsequent analysis. Data were analysed using Spearman correlation and stepwise linear regression using SPSS for Windows.

Results: There was a strong correlation between Ca concentrations on D14 and mucus score and cytology score on D21. Cortisol concentrations were not different between groups on D-14 but on D1 the control group had significantly higher cortisol concentrations compared with both treatment groups. On D14 the CORT+PG group had higher concentrations of cortisol when compared with the control group but these concentrations were not different than those of the CORT only group. IgG concentrations at calving did not differ between the two induced groups but were significantly lower in the control group ($P < 0.05$) when compared with the induced. Treatment group and Ca concentrations on D-14 were strong predictors of IgG concentration. Calf weight at birth was not different between groups and neither was the total weight gain over 10 weeks. There was a strong correlation between total weight gain and the weight gain per week. Calf weight at birth was correlated to mucus score, uterine involution and cytology on D21.

Conclusions: Induction of calving has no negative effects on calf weight gain but can have a positive effect on IgG concentrations in the colostrum. Calcium concentrations on D1 and D14 post calving do have an effect on subsequent reproductive health. Induction with cortisol leads to a decrease in cortisol concentrations at D1 post calving but this is a temporal effect.

Comments: This project was funded by the UCD Seed Funding Scheme - SF827

Estimating the body weight of cattle fetuses before birth by measuring the coronet width with ultrasonography

Honami Tasaki¹ Chikako Tani² Sayuri Harumoto¹ Norifumi Hattori¹ Takashi Kotaka¹ Koichiro Hemmi² Yasuo Moritomo¹ Hiromu Katamoto² Takeshi Osawa² Mineto Tani¹¹Tokai University, Kumamoto, ²University of Miyazaki, Miyazaki, Japan

Objectives: Dystocia is defined as delayed or difficult parturition. The general causes are fetal-maternal size mismatch, fetal malpresentation, and maternal-related causes such as uterine torsion. In particular, an excessively large fetus can cause a dangerous condition for both the cow and the calf in clinical practice. Fetus size is usually estimated from the size of the hoof by rectal examination. However, this method is not effective due to lack of accuracy. The purpose of this study was to use ultrasound images to estimate the weight of a fetus just before delivery from the coronet width (hoof width).

Materials and Methods: A total of 78 calves, – Jersey (12 male, 6 female), Holstein (19 male, 17 female), Japanese Brown (12 male, 8 female) and Japanese Black (2 male, 2 female) – were studied from 2013 to 2015. Experiment A (measuring the hoof width of a fetus): The forelimb hoof width was measured using ultrasonography (linear type 6-10MHz, Ezaote Inc.) via rectum from 10 days before the expected date of delivery. Experiment B (the relationship between hoof width and body weight of the calf): The hoof width of a calf was measured using ultrasonography with the water immersion method (echo value) and a caliper (measured value) within 24 hours after delivery. The body weight of a calf was measured with a digital scale. (Minimum measured quantity: 50g). The relationship of the hoof width and weight was calculated and applied to actual cases.

Results: Experiment A: The hoof width of the fetus was measured from the ultrasound image of the middle phalanx distal cross-section. Experiment B: The gestation period (mean \pm SD) of the Jersey, Holstein, Japanese brown cattle and Japanese black cattle was $282.1 \pm 4.5, 276.0 \pm 5.4, 284.3 \pm 3.8, 290.8 \pm 2.6$, respectively; their body weight (kg) was $28.4 \pm 4.0, 40.0 \pm 5.1, 34.6 \pm 4.8, 27.3 \pm 3.6$; and their hoof width measured value (mm) was $53.9 \pm 2.2, 57.4 \pm 2.8, 56.7 \pm 3.3, 52.0 \pm 3.0$. The relationship between the echo value [X] and the measured value [Y] of the hoof width was $Y = 0.9933X + 1.1124$ ($R^2 = 0.9574$, $P < 0.001$). The relationship between the measured value of the hoof width [X] and weight [Y] is $Y = 1.444X - 42.907$ (Holstein, $R^2 = 0.627$, $P < 0.001$) and $Y = 1.353X - 42.110$ (Japanese brown cattle, $R^2 = 0.860$, $P < 0.001$). Using this equation to estimate fetal weight before parturition allowed for treatments to avoid dystocia, such as parturition induction. Using this weight estimation method was also effective in identifying excessively large fetuses in Japanese brown cattle.

Conclusions: The hoof width of the fetus could be accurately measured using ultrasound imaging. Strong correlation was observed between the hoof width and weight of the calf. This study suggested that it is possible to estimate the weight of a fetus by measuring the hoof width of the fetus using ultrasound image.

Comparison of an alternative diagnostic sampling technique for *Tritrichomonas foetus* in cattle

Grant Dewell¹; Karen Harmon¹; Tyler Dohlman¹; Patrick Phillips¹; Phillip Gauger¹¹Iowa State University, Ames, United States

Objectives: Bovine trichomoniasis is emerging as a major concern in the beef industry. Recent advancements in PCR diagnostics have increased the ability to detect the disease in asymptomatic bulls. However, the greatest limitation is proper collection of an adequate sample. Furthermore, the low repeatability of most sample collection techniques can cause confusion and misdiagnosis. The aim of the study was to validate a sample collection technique that increased sensitivity and was easier and safer to collect than preputial scraping.

Materials and Methods: One hundred eleven commercial bulls of unknown infection status, were sampled for detection of *Tritrichomonas foetus* using two different collection methods: 1) traditional preputial scraping with a dry insemination pipette (TPS) and 2) penile preputial swabbing (PPS). TPS samples were taken by vigorously scraping preputial/penile mucosa using a rigid insemination pipette while applying negative pressure. PPS samples were obtained by briskly swabbing the penile and preputial mucosa with a gauze sponge during full extension of the penis. All samples were processed using InPouch™ TF media and submitted under similar conditions for PCR testing at ISU Veterinary Diagnostic Laboratory.

Results: Positive PCR results were observed in 37 out of 111 (33%) bulls using the traditional preputial scraping technique, however 39 out of 111 (35%) were positive using penile preputial swabbing technique. Sensitivity and 95% Confidence Intervals (CI) was determined with web based application utilizing R software. The Newton-Raphson algorithm predicted the sensitivity of the traditional preputial scraping method was 0.919 (CI 0.689-0.983) and the sensitivity of the penile preputial swabbing was 0.949 (CI 0.818-0.987).

Conclusions: This data indicates that the penile preputial swabbing technique is a reliable alternative to the traditional preputial scraping method. Regulatory veterinarians should consider allowing sponge samples as an official test for trichomoniasis.

P04-004-185

Effect of weaning, non-pregnancy and calf loss on live weight production and efficiency of beef cows in northern Australia

Geoffrey Fordyce¹; Michael R. McGowan²; David Johnston³¹QAAFI, University of Queensland, Brisbane, ²Vet School, University of Queensland, Gatton, ³AGBU, Armidale, Australia

Objectives: To measure annual live weight production and live weight production ratio of cows as a function of mating outcome which is either failure to conceive (E), calf loss (L) or wean a calf (W) during one year

Materials and Methods: Income from beef herds is primarily determined by live weight production. For a cow over one year this is measured

as change in her live weight (at weaning times) plus the weight of calf weaned. Live weight production for a breeding herd is a function of weaner numbers and weight, and cow growth and survival.

Brahman and Tropical Composite females (n=2,127) were first mated at 2 years of age and monitored between 2.5 and 8.5 years of age during which time they had the potential to wean six calves (Johnston et al. 2014). The four age groups of cattle used were allocated to graze pastures on the four major country types in Queensland where they were mated for three months annually. Live weight production ratio was calculated from the 11,566 mating outcomes as annual live weight production divided by the average live weight of the cow-calf unit over the year, the latter being an indicator of feed intake.

Results: Average annual live weight production was:

- 36 and 23 kg less on northern forest (150±43kg) and downs country (163±77kg), respectively, compared to central and southern Queensland (186±69kg).
- 29 kg less in the year after first mating, than subsequently (152±60kg v 181±72kg).
- 74 and 128 kg more in W cows compared to E and L cows (199±59kg, 125±42kg, 71±50kg, respectively). E cows started the year in lower body condition (2.6±0.8; 5-point scale) than L and W cows (3.2±0.7).
- 38-40 kg more if previous mating outcome was W (190±71kg) compared to L (152±75kg) or E (150±62kg).
- 222±53kg and 132±63kg in cows that raised six and three calves in six years, respectively. Cows weaning six calves were in better body condition at weaning (2.8±0.5 v 2.5±0.6) and weaned heavier calves (208±37kg v 201±36kg) than low-fertility cows. Cumulative live weight production was linear in both cow classes.

Average live weight production ratio was:

- 0.34±0.10 kg/kg of cattle for W cows compared to 0.26±0.09 and 0.14±0.10 kg/kg of cattle for E and L cows, respectively.

Conclusions: Calf loss has a larger impact on live weight production of breeding cows than non-pregnancy does, partly because non-pregnant cows are in lower initial body condition. Cows that wean a calf every year appear to have much higher inherent ability to produce live weight from available pasture than low-fertility phenotypes, as indicated by their higher live weight production, heavier weaners, better body condition at weaning and higher live weight production ratio. Variation in live weight production may be associated with the high genetic variation for ability to conceive in tropically-adapted cattle previously reported from this study.

P04-004-186

A Comparison of Double Prostaglandin (PG) and 5 Day Progesterone Implant Co-synch to Breed Beef Heifers with Timed Artificial Insemination (TAI)

Colin Penny¹; Alistair McClelland²

¹Zoetis UK Ltd, Tadworth, ²Academy Vet Centre, Stranraer, United Kingdom

Objectives: A large (1300 cow) extensively managed commercial beef herd in South-West Scotland had been using AI for several years to breed large groups of heifers with variable success. The standard protocol used by the farm was double PG injection followed by TAI at 72 and 96 hours. In an attempt to improve previous TAI results and also reduce handling and AI costs a group of 110 heifers were synchronised with a 5 day CIDR co-synch protocol to compare to the herd's standard double PG breeding protocol.

Materials and Methods: Heifers were Aberdeen Angus, Simmental or Saler crosses and around 18 months of age at breeding in November 2014. The heifers were outdoors at grass and supplemented with silage and rationed cereal based concentrate (2kg/day) during the breeding period. A total of 276 heifers were mated with Double PG : day 1 and day 11 PG injection (0.15mg d-cloprostenol, Prellim@injection, Zoetis) followed by TAI 72 and 96 hours after second PG injection. 110 heifers were mated with 5 day CIDR co-synch protocol: day 1 CIDR (CIDR@1.38g, Zoetis) inserted plus GnRH injection (100µg gonadorelin, Acegon@, Zoetis). Day 5 CIDR insert removed and PG injection. Day 8 (72 hours later) TAI and GnRH injection.

All inseminations were carried out by trained AI technicians and pregnancy was confirmed at approximately 8-9 weeks post AI by ultrasound examination. A basic economic costing for breeding 100 heifers was modelled using manufacturer list price drug costs (CIDR £9.74, PG £2.76, GnRH £3.28) and AI cost of £12 per service (technician labour and semen). Vet and farm labour costs were not included. An average daily liveweight gain (ADG) of 1kg was assumed for calves and liveweight sale value of £2.20/kg. Conception rates were compared using a Chi-square test.

Results: Conception rate to Double PG protocol was 48% (133/276) and to CIDR Co-synch was 63% (69/110; P=0.01).

Economics modelled on 100 heifers bred to each protocol. Double PG protocol : drugs £552; AI costs £2400; cost per heifer bred £29.52; cost per pregnancy generated £61.50. CIDR Co-synch protocol : drugs £1906; AI costs £1200; cost per heifer bred £31.06; cost per pregnancy generated £49.30.

Potential Value of Superior 1st Serve Conception Rate. The superior conception rate to 1st service with CIDR co-synch delivered an additional value of 15 calves/100 heifers born in 1st cycle of mating which could generate an additional 15 x 21kg weaning weight advantage over calves born to next cycle = 315kg @ £2.20/kg LW = £693 (Assuming 1kg ADG and at least 21 days older at weaning).

Conclusions:

- On this farm during the same breeding season the CIDR co-synch protocol delivered superior results to the standard double PG protocol (63% vs 48% CR, P =0.01)
- The superior CR and reduced AI costs led to an economic saving of £12.20 per pregnancy generated despite the greater drug costs associated with CIDR co-synch
- A 15% difference in 1st service CR could also have been worth around £693 / 100 heifers bred due to extra kg of weaned calf weight or £46.20 per extra pregnancy to 1st service
- The 5 day CIDR co-synch protocol may offer significant economic and labour saving advantages over traditional double PG protocol for TAI in beef heifers.

Effects of Injectable Trace-Mineral Supplementation on Reproductive Performance of Beef Cows and Developing Beef Bulls

K. C. Olson ¹, R. L. Weaver ¹, S. L. Hill ¹, L. R. Mundell ¹, J. S. Stevenson ¹, E. Havenga ², L. J. Havenga ²

¹Animal Sciences & Industry, Kansas State University, Manhattan, Kansas, ²Multimin USA, Fort Collins, Colorado, United States

Objectives: Our objective was to evaluate the effects of bolus injections of a trace-mineral solution (TM; 15 mg/mL Cu, 10 mg/mL Mn, 5 mg/mL Se, and 60 mg/mL Zn) or an equal volume of physiological saline (SA) on pregnancy to timed insemination in beef cows (study 1) and on semen-quality characteristics in young beef bulls (study 2).

Materials and Methods: In study 1, beef cows (n = 460; initial BW = 497 ± 89 kg) were stratified by BCS, age, and predicted calving date and assigned randomly to either TM or SA. Treatments were administered to cows (1 mL/90 kg BW) 105 d before calving began and again 30 d before fixed-time AI. Following calving, cows with suckling calves grazed 1 of 5 native-range pastures; treatments were evenly distributed within pastures. Trace-mineral supplements and white salt were available to cows ad libitum before and during study 1. Blood samples were collected from cows 17 and 8 d before fixed-time AI. Serum progesterone was quantified by RIA. Ovulation was synchronized using a 5-d CO-Synch + CIDR protocol; cows were inseminated 72 h after CIDR removal. Cows were exposed to fertile bulls for natural-service breeding 10 d after AI for 40 d. Conception to AI and final pregnancy were assessed 36 d after AI via transrectal ultrasonography and 120 d after AI via rectal palpation, respectively.

In study 2, bull calves aged 7 months (n = 491; initial BW = 314 ± 45 kg) were stratified by breed and ranch of origin and assigned randomly to the same treatments used in study 1. Treatments were administered to beef bulls at 7 months of age (1 mL/45 kg BW) and at 10 months of age (1 mL/68 kg BW). Within treatment, breed, and source strata, bulls were assigned randomly to 1 of 8 pens, where they were fed a growing diet ad libitum for 225 d. The diet was formulated to promote a 1.5 kg ADG at a DMI of 2.6% of bull BW. Breeding soundness examinations (BSE) were conducted at 10 and 12 months of bull age.

Results: In study 1, change in BW and BCS from study initiation to calving and from AI to weaning did not differ (P≥0.15) between TM and SA cows. Conversely, TM cows had greater (P=0.04) BCS increase than SA cows between calving and AI. Proportion of cows with estrous cycles (serum progesterone ≥ 1 ng/mL) ≥ 8 d before fixed-time AI did not differ (P≥0.51) between treatments. In contrast, conception to fixed-time AI was greater (P=0.05) for cows receiving TM (60.2%) than for cows receiving SA (51.2%). Final pregnancy rate did not differ (P=0.24) between treatments and averaged 92%; however, a greater (P=0.01) proportion of TM-treated cows calved in the first 20 d of the subsequent calving season than SA-treated cows (77.5 vs. 65.0%).

In study 2, BW, ADG, and scrotal circumference of bulls were not affected (P≥0.16) by treatment. Proportions of TM- and SA-treated bulls receiving satisfactory BSE scores did not differ (P=0.98) at 10 months of age (50 % for both TM and SA). At 12 months of age, the proportion of TM-treated bulls receiving satisfactory BSE scores was numerically larger (P=0.43) than that of SA-treated bulls (89% for TM and 86% for SA). This change was associated with greater (P=0.05) sperm motility in TM-treated bulls than in SA-treated bulls at 12 months of age; moreover, TM-treated bulls had greater (P≤0.05) improvement in sperm morphology and sperm motility between 10 and 12 months of age than SA-treated bulls. Among bulls that failed BSE at 10 months of age, more (P=0.10)

TM-treated bulls passed BSE at 12 months of age than SA-treated bulls (98 vs. 94%, respectively).

Conclusions: Under the conditions of these studies, pre- and postpartum trace-mineral injections improved conception to fixed-time AI and subsequent calving distribution of beef cows. Sperm motility and morphology at 12 months of age were improved in bulls treated with injectable trace minerals at 7 and 10 months of age compared to bulls treated with saline. Among bulls that were sub-fertile at 10 months of age, more TM-treated bulls passed BSE at 12 months of age than SA-treated bulls

A Double Synchronisation and Artificial Insemination (AI) Breeding Protocol for Beef Cows

Colin Penny¹, Jimmy Hyslop², Isabelle Truysers³

¹Zoetis UK Ltd, Tadworth, ²SAC Consulting, Penicuik, ³Royal (Dick) School of Veterinary Studies, Roslin, United Kingdom

Objectives: The use of AI in beef cows at pasture is limited by the practical problems of heat detection and multiple handling. A double synchronisation protocol was developed to breed beef cows using AI with minimal heat detection and maximise the percentage pregnant to AI in the first 24 days of the breeding period.

Materials and Methods: Spring calving (April-May) Angus or Limousin crossbred beef cows on a single farm in Midlothian, Scotland were bred by AI as described below over four consecutive years. During the breeding programme described all animals were at pasture and suckling calves. Day 0 was defined as the start of AI breeding period. At day -11 cows had progesterone (P) implants (CIDR® 1.38g, Zoetis) inserted and received GnRH injection (0.01mg Buserelin, Receptal™, MSD Animal Health). Seven days later (day-4) all cows received prostaglandin (PG) injection (500µg cloprostenol, Estrumate™, MSD Animal Health). Two days later (day -2) CIDR implants were removed and any cow calved <55 days at this time also received 400iu serum gonadotrophin (PMSG-Intervet, MSD Animal Health) by i/m injection. Fixed time AI (TAI) was carried out twice at 48 and 72 hours after CIDR removal (days 0 and 1). After removal the CIDR implants were washed in dilute chlorhexidine, dried and stored for re-use. On day 16 all cows had the once-used CIDR implants inserted and left in place for 5 days. On day 21 the CIDR implants were removed, tail paint applied and cows observed at pasture for returns to oestrus over the next 72 hours. Cows were gathered on days 23 and 24 and inseminated based on observation of standing to be mounted or tail paint being removed on days 22-24. All inseminations over the 4 year period were carried out by the same experienced technician. Pregnancy diagnosis was carried out by ultrasound around day 35 after AI.

Results: Breeding results from the double synchronisation programme over a 4 year period are summarised below.

First service conception rate (CR) to TAI : 65% (63/97); 67% (102/152); 66% (103/156); 68% (106/156). Mean CR over 4 years 67% (374/561).

Second service CR to observed heats/AI : 59% (13/22); 41% (12/29); 36% (13/36); 58% (18/31). Mean second service CR 47% (56/118).

Cow pregnancy rate after 24 days breeding : 78% (76/97); 75% (114/152); 74% (116/156); 79% (124/156). Mean pregnancy rate after 24 days 77% (430/561).

The P implants appeared to have enough residual P to prevent early returns of non-pregnant cows prior to day 21. The re-use of CIDR implants after washing/disinfection or autoclaving has been described by various authors however is not a licensed use of the product. In the herd described above, used CIDR implants were only used for the 5 day re-synchrony period and were not considered suitable for primary synchronisation.

Conclusions: The synchronisation protocol delivered consistent results (mean 67% CR) over 4 years showing that, under good management, beef cows can be highly fertile at first service after calving when bred to TAI. Resynchronising cows after TAI using P implants can allow a targeted period of heat detection to allow a second round of AI. In this herd the CR to the second round of AI was acceptable at 47% which allowed 77% of cows to be successfully impregnated by AI in a 24 day breeding period. Double synchronisation may be a practical method to breed beef cows by AI with minimal heat detection and could be followed by sweeper bull mating.

Effect of Calving Difficulty on Reproductive Performance and Functional Longevity in Holstein Cows

Navid Ghavi Hossein-Zadeh ^{1,*}

¹Department of Animal Science, University of Guilan, Rasht, Iran, Islamic Republic Of

Objectives: The objective of this study was to evaluate the effect of dystocia on subsequent reproductive performance and functional longevity in Iranian Holsteins.

Materials and Methods: Data consisted of 1,467,064 lactation records of 581,421 Holstein cows from 3083 herds which were collected by the Animal Breeding Center of Iran from April 1987 to February 2014. Reproduction traits in this study included interval from first to second calving, days open and days from first calving to first service. Calvings were scored on a 5-point system of difficulty with increments of 1, where score 1 = unassisted, score 2 = slight assistance, score 3 = considerable assistance, score 4 = considerable force needed, and score 5 = caesarian. The generalized linear model was used for the statistical analysis of reproductive traits. Survival analysis was performed using the Weibull proportional hazards models to analyze the impact of dystocia on functional longevity.

Results: The incidence of dystocia had an adverse effect on the reproductive performance of dairy cows. Therefore, reproductive traits deteriorated along with increase in dystocia score (P<0.05). The culling risk was increased along with increase in the score of dystocia (P<0.0001). The greatest culling risk was observed in primiparous cows, small herds and low- yielding cows (P<0.0001). Also, the lowest culling risk was found for cows calving at the youngest age (<27 months) and cows with age at first calving >33 months had the greatest risk (P<0.0001).

Conclusions: The results of current study indicated that dystocia had important negative effects on the reproductive performance and functional longevity in dairy cows and it should be avoided as much as possible to provide a good perspective in the scope of economic and animal welfare issues in dairy herds.

P03-003-182

Fertility after different resynchronization protocols with timed AI in 32 commercial dairy farms

Raquel Patron ¹Irene Lopez-Helguera ²Javier Heras ³Octavi Fargas ⁴Susana Astiz ^{5,*}

¹TRIALVET SL, Madrid, ²Animal Production, Universitat Lleida, Lleida, ³VETHER, Girona, ⁴VAPL SL, Barcelona, ⁵Animal Reproduction, INIA, Madrid, Spain

Objectives: After first inseminations an average of at least 60% of the cows are usually not pregnant, such that strategies to achieve pregnancy of these cows as soon as possible are very important for profitability of the farms. Different resynchronization protocols using prostaglandin (PG) and GnRH with timed artificial insemination (TAI)

have been designed. The mean objective is to maximize the pregnancy rate, sharply influenced by the interval AI-pregnancy diagnosis.

The aim of this study was to evaluate fertility and pregnancy rate of resynchronization protocol.

Materials and Methods: Data of 4279 inseminations of cows coming from 32 different commercial farms distributed in the East region of Spain were included. The average farm size was 400 lactating cows (range between 90 and 1400 cows/farm) and 10.507L/cow/lactation. The resynchronization protocols compared were G6G (n=3574 AI; PG at day 0, GnRH at day 2, day 8 GnRH, day 15 PG, day 15 PG; day 16 p.m. GnRH and TAI at day 17) versus 5days-Ovsynch (5DO; n=705 AI; GnRH at day 0; PG at days 5 and 6; day 7 p.m. GnRH and TAI at day 8). Risk factors included were parity (primiparous vs. multiparous) and season at TAI (hot vs. cool season).

Results: Farm significantly affected fertility (P<0,001) ranging between 17-59% with an averaged fertility of 36.4±12.9% and included as factor in the regression model. Parity did not show a significant influence on the fertility (36.42±12.39 vs. 36.4±13.8% for multiparous and primiparous respectively; P>0.05). On the other hand, season and synchronization protocol significantly affected fertility. During the hot season the fertility was 23.5±8.7% and during the cool season it was 40.8±11.0% (OR=2.241; P<0.001). Finally, the fertility of inseminated cows after G6G was 38.1±12.3 and after 5d-Ovsynch 26.5±12.2% (OR=1.477; P<0.001). When parity was conserved in the model, the difference in fertility in multiparous showed the same effect (G6G was significantly better than 5d-Ovsynch), however, in primiparous, this difference showed only a statistical tendency to be better with G6G versus 5d-Ovsynch (38.0±12.8 vs. 31.1±15.4%; P=0.06).

The difference between TAI-TAI in the protocols is essential to decide the best strategy to obtain the best pregnancy rate. Given an interval for pregnancy diagnosis of 31d, the insemination rate with G6G-protocol (interval TAI-TAI of 18d and subsequent insemination rate of 43%) and the fertility of 38% gave a pregnancy rate of 16%. With the 5d-Ovsynch protocol, the TAI-TAI interval of 9d gives an insemination rate of 50%. This would allow a fertility as low as 32% to get the same pregnancy rate than with the G6G. With larger interval AI-Pregnancy diagnosis, the fertility allowed for 5d-Ovsynch can be reduced to get the same pregnancy rate than with G6G.

Conclusions: G6G fertility was higher than that after 5d-Ovsynch protocol, but the interval TAI-TAI reduction of the shorter protocol allows a lower fertility to get the same pregnancy rate at a fixed interval AI-pregnancy diagnoses. These factors should be considered, when a decision has to be taken.

Associations between the intrauterine cytobrush procedure in dairy cows and purulent vaginal discharge, reproductive performance and milk production

Melvin De Boer ^{1,*}Scott McDougall ¹

¹Cognosco, Morrinsville, New Zealand

Objectives: Reproductive tract inflammation and infection have a negative impact on reproduction performance and there are a number of diagnostic tools available to assess those diseases. Cytology using cells recovered by transcervical placement of a human pap-smear brush

has been a frequently used method in dairy reproductive research in the last 10 years. The objective of this study was to assess the associations between the use of the cytobrush and subsequent diagnosis of purulent vaginal discharge (PVD), reproductive performance, and milk production.

Materials and Methods: Dairy cows (n=272) from 6 spring-calving dairy herds in the Waikato, New Zealand were assessed at 3 time points postpartum; D0 (median: 2; range: 1-7 days in milk), D21 (±0), and D42 (±2). On D0 and D21 two intrauterine samples were collected via triple guarded cytobrushes. The first cytobrush was used for bacteriological assessment of *E. coli* and *T. pyogenes*. The second cytobrush was used to prepare a cytology slide. On D42, PVD was evaluated on a 0 to 5 scale (>1 defined as PVD positive) using a Metrichheck device™, (Simcrotech, Hamilton, New Zealand). Milk production at one time point was assessed (median interval between seasonal planned start of calving to herd milk production test=120 days; range=91-141 days). Milk production was categorized in low milk solids (MS; ≤mean MS for each herd - SD), medium MS (>mean MS for each herd - SD to ≥mean MS for each herd + SD) and high (>mean MS for each herd + SD). Mean MS minus & plus SD for herd 1 were 1.41 & 2.19 kg MS, respectively, and 1.43 & 2.21, 1.55 & 2.44, 1.43 & 1.87, 1.16 & 1.53 and 1.62 & 2.18 kg MS for herds 2, 3, 4, 5, and 6, respectively. Cows assessed with the cytobrush procedure were matched 1:2 by herd, age (categorized in 3 and 4, 5 and 6, and >6 years old) and breed (Friesian, Jersey, and Cross breed) with cows that were not sampled. Associations were examined using multivariable conditional logistic regression for matched studies.

Results: The cytobrush procedure increased the odds of PVD at a median of 44 days post-partum, with 20/265 (8%) cases and 17/530 (3%) controls having PVD, respectively (OR=4.05 (95%CI= 1.81-9.05); P=0.001). Interestingly, the procedure was associated with increased odds of pregnancy by 42 days after the start of the seasonal breeding programme (planned start of mating; PSM), with 155/265 (58%) cases and 230/530 (43%) controls pregnant at 42 days after PSM, respectively (OR=1.55 (95%CI= 1.15-2.33); P=0.01).

Additionally, with low milk production as the reference, cases were more likely to have a medium milk production compared to controls, with 31/263 (12%) cases and 81/528 (15%) controls having a low production, 206/263 (78%) cases and 360/528 (68%) controls having a medium production, and 26/263 (10%) cases and 87/528 (16%) controls having a high production, respectively (OR=1.83; P=0.02 and OR=0.95; P=0.90 for medium and high milk production, respectively).

Conclusions: The cytobrush procedure to detect uterine inflammation and intra-uterine presence of bacteria increased the probability of having and being treated for PVD 44 days post-partum. Interestingly, the cytobrush procedure was also associated with increased probability of conceiving in the first six weeks after PSM and with increased probability of having a medium milk production compared to control cows.

Treatment Of Puerperal Metritis In Dairy Cows Using Two Antibiotics Combined Or Not With A Prostaglandin F2alpha Analogue

Carlos Fernandes^{1,2} Ana Cristina Figueiredo² Miller Palhão¹ Jairo Neves¹ Henderson Ayres³ João Paulo Barbuio³ Denis B. A. Antônio³

¹Animal Reproduction, University of Alfenas, ²Animal Reproduction, Biotran LTDA, Alfenas, ³MSD Saude Animal, São Paulo, Brazil

Objectives: Uterine infections are one of the main causes of reduced fertility in dairy cows. Puerperal infections are frequent after dystocia and retained placenta. Besides the negative impact in fertility, uterine infections can eventually cause cattle death; thus, effective treatments are important to avoid economical losses. The objective of this study was to evaluate the efficacy of two antibiotics, associated or not with sodium cloprostenol (SC), in the treatment of puerperal infections in dairy cows.

Materials and Methods: Holstein cows (N=100) showing retained placenta 18 to 36 hours after birth were selected for this study. These cows were randomly allocated in 4 treatment groups, balanced according to parity and body condition score, in a factorial 2x2 design (2 antibiotics, combined or not with SC). The treatments were given im at the first day after calving as follows: T1 (n = 25), cefquinome (Cobactan, MSD Saude Animal, Sao Paulo, Brazil), 1mL / 25kg body weight (BW) once a day for 3 days; T2 (n = 25), cefquinome in the same protocol of T1 plus 0.5 mg of SC (Ciosin, MSD) at the first and third days of treatment; T3 (n = 25), oxytetracycline hydrochloride (Terramycina LA, Zoetis, Sao Paulo, Brazil) for two days at 48-h interval; and T4 (n = 25), oxytetracycline in the same protocol of T3 plus 0.5mg SC on the first and third days of treatment. Rectal temperature was measured daily for five days postpartum. The cows were evaluated between the third and fifth weeks postpartum by rectal palpation, ultrasonography, and vaginoscopy, to assess the presence of uterine infection (endometritis). We evaluated the interval from calving to first service, the conception rate at the first insemination, the number of pregnant cows up to 250 days after parturition, the average number of services per conception, and the number of days open (Tukey test). A p-value of 0.05 indicated statistical significance.

Results: The percentage of cows showing hyperthermia (temperature >39.0°C) between the second and the fifth day postpartum was 12.0%^a; 8.0%^a; 40.0%^b and 24.0%^{ab} for T1, T2, T3, and T4, respectively (P<0.05). The percentage of cows diagnosed with endometritis between the third and fifth weeks postpartum was better in cefquinome groups (36.0%^a; 24.0%^a; 64.0%^b and 48.0%^{ab} for T1, T2, T3, and T4, respectively - P<0.05). The interval from calving to first service (67.7±18.6^b, 53.2±13.8^a, 74.0±22.7^c, and 64.7±15.1^b days), the percentage of pregnant dairy cows up to 250 days postpartum (76.0%^{bc}; 88.0%^c; 56.0%^a, and 68.0%^{ab}), and the number of days open (158.5±86.4^b, 144.6±72.0^a, 179.8±96.2^c, and 161.3±81.2^b days) differed between treatments T1, T2, T3, and T4, respectively (P<0.05). However, there was no difference in the conception rate at the first AI nor in the number of services per conception among treatments (24.0%; 32.0%; 16.0%, and 20.0% and 3.2±1.8, 2.9±1.5, 3.5±2.0, and 3.3±1.9 for T1, T2, T3, and T4, respectively; P>0.05).

Conclusions: Cefquinome is more efficient than oxytetracycline hydrochloride in the treatment of puerperal metritis in dairy cows with retained placenta. Prostaglandin treatment of cows with retained placenta and subsequent uterine infections, improved fertility by reducing the number of days open, independent of the antibiotic used.

Fixed-time artificial insemination following progesterone-based synchronization protocols associated with GnRH or estradiol in Holstein heifers

Rafael H. Alvarez¹ Alfredo J. Melo¹ Fabio Luis N. Natal¹ Claudio A. Oliveira²

¹Polo Regional Centro Sul, Agency for Agribusiness Technology of São Paulo, Piracicaba, SP, ²Animal Reproduction Department, FMVZ/USP, São Paulo, SP, Brazil

Objectives: Due to the low cost and good results in pregnancy rates, administration of estrogen, concurrently with a progesterone device, is the most widespread hormonal protocol used in Brazil for fixed-time artificial insemination (FTAI) in beef and dairy cattle. However, legal restrictions of the use of estrogens in animal products should limit the use of these substances in the near future. The aim of this study was to evaluate the conception rates of Holstein heifers treated with an alternative protocol (5-day CO-Synch + CIDR) to the conventional 8-day progesterone-based synchronization protocol associated to estradiol.

Materials and Methods: Pubertal Holstein heifers (n=143) were treated (Day 0) with a progesterone intravaginal device (Primer®, Tecnopec, São Paulo, Brazil) containing 1 g of progesterone and assigned randomly in two groups. Group 1 (n=75) was injected with GnRH (100µg i.m. Cystorelin, Merial, Duluth, GA, USA) and group 2 (n=68) with estradiol benzoate (2mg EB, Estrogin, Farmavet, São Paulo, Brazil). Primer was removed on Day 5 (group 1) or Day 8 (group 2) and administered one injection of cloprostenol (125 mcg, Prolise®, Tecnopec, São Paulo, Brazil). Twenty-four hours later, Group 2 received 1 mg EB. Estrus was monitored (Estrotec®, Rockway, Inc. USA) after cloprostenol injection and FTAI (semen from one sire) 72 (Group 1) or 54 (group 2) hours after Primer removal, and GnRH was administered concurrent with FTAI in Group 1. Heifers from group 1 showing estrus until 54 hours after cloprostenol injection were inseminated at the end of estrus. Pregnancy status was evaluated by transrectal ultrasonography on day 40 after FTAI. The effect of treatments in pregnancy rates after FTAI was analyzed by the GLIMMIX procedure of SAS. The variables included in the model were: age, weight, estrus manifestation, follicle size at time of insemination and interaction of the main effects.

Results: The pregnancy rate was not affected by age, weight, follicle size or estrus manifestation (P>0.05). Most heifers of group 2 (88.2%) than group 1 (33.3%) were in estrus at FTAI (P<0.05). On the other hand, 40% of heifers of group 1 showed estrus in the 24 hours to 54 hours period after cloprostenol injection. The pregnancy rate of heifers inseminated at standing estrus in this period was 50.0% vs 48.9% at FTAI (P>0.05). At all, pregnancy rate of groups 1 (IA + FTAI) and 2 (only FTAI) were 49.3 and 51.5%, respectively (P>0.05).

Conclusions: Similar pregnancy rates can be achieved with the 5-day Co-synch and BE protocols. However, considering the high proportion of heifers of group 1 that were inseminated on standing estrus in the period < 54 h after injection of cloprostenol, further studies are necessary to elucidate if co-synch protocol can be considered adequate to FTAI.

Financial support: Fapesp (grant 2011/14358-9)

Objectives: Identification of open cows and their enrollment in a suitable synchronization protocol is an essential part of improved reproductive management in any dairy enterprise. The objectives of the study were to appraise the controlled internal drug release (CIDR) based protocols to synchronize estrus followed by resynch and to compare their fertilizing ability through fixed time artificial insemination (FTAI) in postpartum dairy cows at two different geographical locations

Materials and Methods: In Experiment 1 (location A), postpartum cows (n=160) were assigned to receive standard CIDR-EB (estradiol benzoate) synchronization protocol. Cows were inseminated artificially, using frozen thawed semen, 48-60 hours after CIDR removal and randomly assigned into two groups: 1) RESYNCH group (n =90) received CIDR for d14-d21 post TAI. On day 23rd, all the cows received 100 µgGnRH (Dalmareline, Fatro Italy; i.m.) while their pregnancy was diagnosed on d30 through ultrasound (US). Open cows in RESYNCH group received PGF2α (Dalmazin, Fatro Italy; i.m) and GnRH following standard ovsynch protocol. Pregnancy was confirmed and reconfirmed on d60 and d90, respectively. Blood sampling was done on day 14, 16 and 30 for P4 analysis. 2). CONTROL group (n =70) subjected to AI after detected estrus from 18-30 days post TAI. PD timeline was same as in RESYNCH group. Corpus luteum (CL) cross-sectional area was measured on d30 in pregnant animals in both RESYNCH (n=30) and CONTROL (n=27) group. In experiment 2, both RESYNCH (n=54) and CONTROL (n=64) groups were similarly treated but without blood sampling and CL area measurement

Results: Effect of CIDR based synchronization and RESYNCH treatment on first-service conception rates and overall pregnancy rates were determined by chi square analysis in PROC FREQ of SAS. Effect of treatment on circulatory P4 profile and luteal tissue cross sectional area were analyzed by using GLM procedures of SAS. Differences were declared significant if p< 0.05. In experiment 1, pregnancy rate on d30 between RESYNCH (48%) and CONTROL (43%) groups did not differ statistically (p=.50). On d60 and d90 overall pregnancy rate was 73 % and 44% (P = 0.002) and 72 % and 43% (P = 0.002) in RESYNCH and CONTROL groups, respectively. Overall pregnancy loss in CONTROL (11%) group was higher in comparison with RESYNCH (4%) group. In experiment2, pregnancy rate on d30 in RESYNCH (54%) and control (44%) groups did not differ statistically (p=0.28). Overall pregnancy rates on d60 and d90 were 72 % vs. 70% and 53% vs. 50% in RESYNCH and CONTROL (P = 0.03; P = 0.025) groups respectively with overall pregnancy loss in RESYNCH (3%) and control groups (14%) group. Mean plasma P4 profile (ng/mL) was measured in control versus RESYNCH group on d14 (5.50± 1.12 vs.5.38± 0.96; p=0.53), d16 (6.47± 0.99 vs. 5.60 ± 1.15; p=0.0036) and d30 (7.57± 1.14 vs. 6.34± 1.32; p=0.0002) post TAI. Mean luteal cross-sectional area on d30 post TAI was measured in both RESYNCH and CONTROL groups was 422±98 and 490± 127mm²; p= 0.03). Other parameters including BCS, cyclicity and parity did show any impact on pregnancy neither independently nor in interaction with treatment

Conclusions: In conclusion, we observed a significant increase in overall pregnancy rate in RESYNCH group in comparison with CONTROL. CIDR based RESYNCH protocol has resulted in significantly higher conc. of P4 despite of small luteal tissue area as compared to control group on d30 post TAI.

Administration of oral calcium in cows diagnosed with toxic puerperal metritis: Cure and subsequent incidence of periparturient health disorders

Pablo Pinedo^{1,2}, Juan Velez³, Gilberto Solano⁴, Nelson Rodriguez⁴,
Julliane de Rezende Naves⁵, Gustavo Schuenemann⁶, Carlos Risco⁷

¹Department of Animal Science, Colorado State University, Fort Collins, CO 80525, ²Texas A&M AgriLife Research, Amarillo Center, Amarillo TX, ³Aurora Organic Farms, Platteville, CO, ⁴Aurora Organic Farms, Cold Water TX, United States, ⁵School of Veterinary Medicine, University of São Paulo, Pirassununga, SP, Brazil, ⁶College of Veterinary Medicine, The Ohio State University, Columbus OH, ⁷College of Veterinary Medicine, University of Florida, Gainesville, FL, United States

Objectives: The objective was to evaluate the effect of oral calcium administration on the cure, survival, reproductive performance, and subsequent presentation of periparturient health disorders (clinical and subclinical mastitis, pneumonia, and lameness) of Holstein cows diagnosed with toxic puerperal metritis (TPM) in an organic dairy farm in Texas, USA. A secondary objective was to analyze the effect of metabolic status at calving (calcium and nonesterified fatty acids [NEFA] serum concentrations) on the incidence of TPM and other diseases during early lactation (clinical and subclinical mastitis, pneumonia, and lameness).

Materials and Methods: Cows with TPM were defined as having an enlarged uterus and a fetid watery red-brown vaginal discharge, associated with systemic illness and fever, within 12 d postpartum. Cows diagnosed with TPM (n=200) were blocked by parity and randomly assigned into 1 of 2 intrauterine treatments applied every other day for a total of 3 treatments: i) Control (CON)=Optimum UterFlush® (Van Beek Natural Science, USA) =3.75 mL diluted in 117 mL of distilled water (n=100); ii) Calcium supplemented (CA)=Same intrauterine treatment plus 6 calcium oral capsules ('O' Cal-D Cap™, Bio-Vet Inc., USA; Ca 7,500-9,000 mg/capsule) once per day, for 3 days. All enrolled cows received hypertonic saline solution (500 ml 7.2% i.v.), dextrose (500 ml 50% i.v.), and oral aspirin (5 boluses/d). Outcome variables included fever, presence of fetid vaginal discharge, and cervix diameter at study d 6 and d 14, clinical endometritis at 32 DIM, survival at 30 and 100 DIM, reproductive performance, and incidence of health disorders after TPM recovery. A group of 200 healthy cows was matched to the enrolled cows (by parity, DIM, BCS) and calcium and NEFA serum levels were determined at calving and at the time of enrollment. Calcium was also measured in the TPM cows at d 1, 2, 3, and 6 post diagnosis. Control variables were parity, BCS at enrollment, and d at diagnosis. Differences between treatment groups were tested by logistic regression, repeated measures analysis, and ANOVA. The significance level for inclusion in the final model was set at $P \leq 0.10$. Significance was set at $P \leq 0.05$.

Results: No difference was found for Calcium treatment effect on fever, presence of fetid vaginal discharge, and cervix diameter at study d 6 and d 14. Similarly, clinical endometritis at 32 DIM and survival (30 and 100d) were not affected by treatment. However, the proportion of cows bred by 200 DIM was affected by Calcium treatment (66% vs. 55% for CA and CON groups, respectively [$P < 0.05$]). Serum concentrations for calcium at d 1, 2, 3, and 6 post diagnosis was significantly higher in the CA treatment. The odds of TPM were significantly higher for cows with low calcium levels at calving (Ca < 8 mg/dL; odds ratio [95%CI] = 2.07 [1.27-3.36]). Similarly, the odds of TPM for cows in severe negative energy balance (NEFA >0.5 mmol/L) were 3.3 (2.03 – 5.35) times the odds of TPM for healthy cows. At the day of TPM diagnosis serum calcium was lower in TPM cows compared with healthy cows (6.29 vs. 8.39 mg/dL; $P < 0.001$). Similarly, NEFA serum concentrations were

higher in TPM cows compared with healthy cows (0.49 vs. 0.35 mmol/L; $P < 0.001$). Finally, the odds of pneumonia for cows in severe negative energy balance were 3.86 (1.1 – 14.7) times the odds of pneumonia for healthy cows.

Conclusions: Supplementing oral calcium to the treatment of toxic puerperal metritis had no effect on clinical cure or survival, but resulted in a higher proportion of cows bred at 200 DIM. Hypocalcemia and high NEFA levels at calving were significant risk factors for occurrence of TPM and cows affected with TPM had lower calcium and higher NEFA concentrations at the time of diagnosis.

P03-003-189

Addition of eCG to a G7G protocol: effects on ovarian dynamics in lactating dairy cows in New Zealand pastoral system

Jimena Yapura¹, Ray Castle², Richard Olde Riekerink², Richard Emslie²

¹IVABS, Massey University, Palmerston North, ²Bayer New Zealand Ltd., Auckland, New Zealand

Objectives: 1) To observe and record the ovarian response of anoestrus and cycling lactating dairy cows to a G7G synchrony protocol, and 2) to evaluate the effect of the addition of eCG to the final prostaglandin injection of a G7G synchronisation program on follicle dynamics and luteolysis in lactating dairy cows.

Materials and Methods: After balancing for cyclicity status (anoestrus vs cycling) at initiation of treatment based on ultrasound examination, 64 lactating cows were treated intramuscularly as follows: on Day -17 (Day 0 = timed-AI) cows were treated with 100 µg of GnRH (pre-G, Ovurelin) and 500 µg of sodium cloprostenol (pre-P; PG, Ovuprost). Seven days later (Day -10), cows were given GnRH (1G; first treatment of Ovsynch) followed on Day -3 by a dose of PG plus or minus 400 i.u. of eCG (Pregnecol reconstituted in Ovuprost, n=32/group). A final dose of GnRH was administered 48 hr later (2G, Day-1) and timed-AI was scheduled 16-20 hours after 2G (Day 0). Animals detected in heat between Days -3 and 0 were inseminated 12 h later (am/pm rule) and were removed for further analysis. Twice daily ultrasound examinations were conducted from Day -3 until timed-AI and repeated 24 h later for detection of ovulation. Progesterone (P4) concentration was assessed on Days -3 and 0 (at timed-AI) in blood samples collected via coccygeal venepuncture.

Results: On Day -3, 95.3% of cows had luteal tissue at ultrasonography (14/17 and 47/47 of anoestrus and cycling cows, respectively) and mean P4 concentration was 5.0±0.53 ng/mL (2.6±0.56 and 5.4±0.52 ng/mL in anoestrus and cycling cows, respectively; $P < 0.01$). Fifty-five percent of cows (35/64) had at least two CLs on Day-3, which was considered indicative of ovulatory response to the pre-G/pre-P treatment (41% and 60% in anoestrus and cycling cows, respectively; $P = 0.26$). No effect of treatment, time and their interaction was detected on day-to-day dominant follicle and CL diameter profiles and 59 of 61 cows underwent morphologic luteolysis, defined as progressive and sustained decrease on CL diameter over 4 consecutive examinations. Six cows (two in G7G and four in G7G+eCG) showed signs of oestrus prior to timed-AI and were inseminated earlier. On Day 0, blood samples were obtained from 48 of 53 cows presented for timed-AI. Mean P4 concentration at AI was 0.3±0.03 ng/mL (0.3±0.03 and 0.4±0.05 ng/mL in G7G and G7G+eCG, respectively). Two out of 25 and two out of 23 cows in the G7G and G7G + eCG groups had P4 concentrations ≥0.6 ng/mL at

timed-AI. Percentage of cows that ovulated to the 2G administration was 96.2% (51/53). Pre-ovulatory dominant follicle diameter was 19.8 ± 0.41 and 19.5 ± 0.63 mm in G7G and G7G+eCG, respectively. Overall, the percentage of synchronised animals (with CL at ultrasonography on Day-3, undergoing morphologic luteolysis and ovulating synchronously after 2G treatment) were 84.4% (27/32) and 75% (24/32) in the G7G and G7G+eCG groups, respectively ($P=0.54$).

Conclusions: Acceptable ovulation rates and progesterone concentrations in cycling and anoestrus cows synchronized with a G7G program could eliminate the need for detection of cyclicity prior to the planned start of mating. Addition of eCG reconstituted in the PG solution did not affect the ovarian dynamics measured in this trial. Although pending at submission of this abstract, the pregnancy rate results from this study and from a larger study run in parallel, will be pivotal to validate whether addition of eCG to the G7G program has positive effects on fertility in lactating dairy cows, overcoming the effect of ovarian status at initiation of treatment.

Effects of prolonged consumption of water with elevated nitrate levels on body condition score and certain reproductive parameters of dairy cattle

M.A. Karatzia¹, P.D. Katsoulos¹, P. Florou-Paneri², H. Karatzias¹

¹Clinic of Farm Animals, School of Veterinary Sciences, ²Laboratory of Animal Nutrition, School of Veterinary Sciences, Aristotle University of Thessaloniki, Greece, Thessaloniki, Greece

Objectives: Water is the most common source of nitrates in non-grazing animals. Ingested nitrates are converted to nitrites and then to ammonia by rumen flora. As this mechanism overloads, nitrite builds up and enters blood stream. Alterations on certain metabolic pathways, due to increased ammonia production and/or nitrite absorption could impair dairy cattle productivity in chronic subclinical nitrate toxicity. The objective was to evaluate the effects of prolonged consumption of water naturally contaminated with nitrates on body condition score and certain reproductive parameters and whether dietary inclusion of clinoptilolite could ameliorate these.

Materials and Methods: Two experiments were run simultaneously for the purpose of the study. In the first experiment (Exp.1) farms 1 and 2 were assigned into two groups according to the nitrate levels in the borehole water of the previous year. The first group (NG) consisted of the farm 1 (milk yield; MY 35 kg/cow/day) that had nitrate levels >40 ppm and the second one (CG) of the farm 2 (MY 36 kg/cow/day) that had water nitrate levels <40 ppm. In the second experiment (Exp.2) farms 3 and 4 were assigned into two groups according to the nitrate levels in the borehole water and the use of clinoptilolite as follows: the first group (NC) consisted of the farm 3 (MY 31 kg/cow/day) that had nitrate levels >40 ppm and used clinoptilolite as feed additive at the rate of 2.5% of concentrates. The second one (CG) consisted of the farm 4 (MY 29 kg/cow/day) that had water nitrate levels <40 ppm without adding clinoptilolite in the ration. Both experiments lasted 6 months. Each farm was visited 3 times, at the onset of the experiment and then at 3-month intervals. At each visit, 15 clinically healthy dairy cows, 5 in early lactation (<150 days in milk; DIM), 5 in late lactation (≥ 150 DIM) and 5 dry cows were selected randomly for body condition scoring (BCS). Certain reproductive parameters (calving to first service interval and number of services per conception) from all cows that delivered and

received at least one insemination during the study period, as well as the data concerning the nitrate levels at the borehole water were obtained from the records of the farms. The data was analyzed with SPSS® v. 21.

Results: The average water nitrate levels during the experimental period were 87 ± 12.5 ppm for farm 1, 4 ± 1.5 ppm for farm 2, 13 ± 2.4 ppm for farm 3 and 76 ± 14.2 ppm for farm 4. The reproductive data of 69 cows (36 in NG and 33 in CG) in Exp. 1 and 50 (23 in NC and 27 in CG) in Exp. 2 were used in the study. BCS was unaffected by prolonged nitrate consumption in both experiments ($P>0.05$). Calving to 1st service interval tended to be significantly higher in nitrate groups in both experiments (Exp. 1: 121.5 ± 7.68 and 102.5 ± 7.25 for groups NG and CG, $P=0.078$; Exp. 2: 114.3 ± 6.45 and 98.5 ± 5.33 for groups NC and CG, $P=0.063$). The number of services per conception was significantly higher in NG compared to the CG (2.21 ± 0.15 and 1.77 ± 0.14 for groups NG and CG, $P<0.05$) in Exp. 1, but no significant difference was detected between groups NC and CG in Exp. 2 (1.71 ± 0.14 and 1.63 ± 0.13 for groups NC and CG, $P>0.05$).

Conclusions: The results obtained provide evidence for possible impairment of the reproductive efficiency of dairy cattle that consume water with high nitrate levels for a prolonged period of time. These effects can be partially controlled by the dietary administration of clinoptilolite.

Influence of Intravenously Glucose Infusions in Pre-estrus on Cycle Length and Further Parameters of the Estrus Cycle in Lactating Dairy Cows

Stephan Groeger¹, Hartwig Bostedt², Axel Wehrend³

¹Bayer Animal Health GmbH, 51373 Leverkusen, Germany, 51373 Leverkusen, ²Clinic for Obstetrics, Gynaecology and Andrology of Large and Small Animals with Veterinary Ambulance of Justus-Liebig-University Giessen, ³Clinic for Obstetrics, Gynaecology and Andrology of Large and Small Animals with Veterinary Ambulance of Justus-Liebig-University Giessen, 35392 Giessen, Germany

Objectives: Delayed ovulation is one of the reproduction disorders in lactating dairy cows which subsequently influences conception rate. Among others a significant positive correlation between daily milk yield and the incidence of delayed ovulations has been demonstrated. The objective of this study was to test whether an energy supply by intravenously administered glucose infusions at different days in pre-estrus affects cycle length, size of the preovulatory follicle, plasma concentrations of progesterone and estradiol-17 β and expression of estrus behavior in dairy cows beyond negative energy balance after parturition.

Materials and Methods: Follicular development and time of ovulation were documented in ten multiparous lactating Holstein Friesian dairy cows by means of daily transrectal sonography (8 MHz transrectal probe, LCS Scanner 100®, Pie Medical, Maastricht, NL). Blood samples were taken once daily starting day 17 of the estrus cycle to determine concentrations of glucose, progesterone and estradiol-17 β until day 5 after ovulation. In every cow three unmanipulated cycles (group 1; control; n = 30) and three cycles after infusion of 1000 mL 5% glucose solution on day 18 (group 2; n = 10), 19 (group 3; n = 10) and 20 (group 4; n = 10) were investigated.

Results: Glucose infusion on day 19 (group 3) resulted in a significant shortening of the cycle length compared to controls (21.3 ± 1.3 vs. 23.3

± 1.9 days; $p < 0.01$). Treatments on the 18th (23.0 ± 1.8) and the 20th day of the estrus cycle (22.6 ± 1.6) had no significant effect, respectively. Treatment did not influence maximum diameter of the preovulatory follicle ($p > 0.05$), but it varied significantly in between the ten individual cows ($p = 0.018$). There was a trend to detect more cows in heat after intravenously glucose administration on day 19 (56.7 % of cycles in group 1 vs. 90 % in group 3) but this difference could not be proven significantly ($p = 0.12$).

Conclusions: Even though the negative correlation between energy status and fertility in high-yielding dairy cows is well established nearly all studies focus on the period of negative energy balance after parturition. These results show that also beyond this period a short-term supply of energy at the beginning of pre-estrus has a significant effect on time of ovulation.

Influence of Preovulatory Glucose Infusions on the Secretion of Luteinizing Hormone and the Time of Ovulation in Lactating Dairy Cows

Stephan Groeger¹*Hartwig Bostedt²Axel Wehrend²

¹Bayer Animal Health GmbH, 51373 Leverkusen, Germany, 51373 Leverkusen, ²Clinic for Obstetrics, Gynaecology and Andrology of Large and Small Animals with Veterinary Ambulance of Justus-Liebig-University Giessen, 35392 Giessen, Germany

Objectives: One of the reasons for the decline in reproductive efficiency of dairy cows is disorders in the ovulatory process like e.g. delayed ovulation. Reports about its incidence vary between 17 – 46 % of the examined cows. An insufficient energy supply at the time of ovulation may contribute to this effect. In a preceding study we demonstrated a shortening of the estrus cycle length by intravenous infusion of glucose at day 19. The aim of the present study was therefore to test the effect of this treatment on the preovulatory secretion of Luteinizing Hormone (LH), estradiol-17 β , progesterone and glucose.

Materials and Methods: The ovaries of ten multiparous lactating Holstein Friesian cows, which were kept in tie-stalls, were examined every two days and from a diameter of the dominant follicle over 10 mm on daily via transrectal sonography (8 Mhz transrectal probe, LCS scanner 100, Pie Medical®, Maastricht, NL) for patterns of follicular growth and time of ovulation. From day 17 of the estrus cycle until day 5 after ovulation blood samples were collected to determine serum concentrations of progesterone, estradiol-17 β and glucose. Cows were randomly allocated into two groups: In group 1 ($n = 5$) cows received an intravenously infusion of 1000 mL of a 5% glucose-solution and in group 2 ($n = 5$) cows received an infusion of 1000 mL 0.9 % saline-solution on day 19 of the estrus cycle. Blood samples for the determination of the preovulatory LH-concentrations were taken every three hours from the end of the treatment until ovulation.

Results: Mean length of estrus cycles was shorter in group 1 compared to group 2 (20.2 ± 1.1 days vs. 21.8 ± 0.8 days; $p = 0.18$). The LH-peak-concentrations differed significantly between the two groups ($p = 0.043$), being much lower in group 1 after glucose infusion (geometric mean 12.27 ng/ml) than in group 2 (control; geometric mean 34.36 ng/ml). The interval between infusion and LH-peak was distinctly shorter in group 1 (25.8 ± 9.6 hours) than in group 2 (52.8 ± 35.7 hours; $p = 0.21$), whereas the intervals between LH-peak and ovulation did not differ between

groups. No significant differences in the concentrations of glucose could be detected.

Conclusions: A short-term supply of glucose on day 19 of the estrus cycle shortens the cycle length by an earlier induction of the preovulatory LH-peak. It is well known that the application of glucoprivic drugs (like 2-deoxy-D-glucose) rapidly suppresses LH-pulses in rodents and in sheep. Thus LH-secretion responds directly to changes in metabolic fuel oxidation. Also in dairy cows the preovulatory LH-secretion seems to be influenced directly by the availability of glucose.

Relationship between scrotal circumference, weight, growth, age, attainment of puberty and Australian Breeding Values in pasture based dairy bulls.

Rosemary Waite^{1,2}*Craig Dwyer²David Beggs¹Peter Mansell¹Michael Pyman¹

¹Faculty of Veterinary and Agricultural Sciences, University of Melbourne, Melbourne, ²Smithton Veterinary Service, Smithton, Australia

Objectives: Natural service sire use post artificial insemination in dairy herds in South Eastern Australia is common. The bull breeding soundness exam (BBSE) provides a tool to assess the risk of subfertility in bulls and whilst it has been extensively used in the beef industry, its use in dairy is increasing.

In order to inform the use of the BBSE in dairy bulls this project aims to collect data on scrotal circumference and weight in growing dairy breeds. Furthermore, semen collections will monitor attainment of puberty. Possible links between scrotal circumference, weight and Australian Breeding Values will also be investigated.

Materials and Methods: The scrotal circumference and live weight of two groups of growing pasture based bulls were monitored at 6 weekly intervals. The groups comprise the two major dairy breeds used in the area, Jersey ($n=85$) and Holstein-Friesian ($n=145$).

Semen samples collected via electroejaculation were taken around the time of puberty as predicted by scrotal circumference. Holstein-Friesian bulls have been determined to reach puberty at a scrotal circumference of 28cm. In order to capture data before and after this stage semen sampling was instituted when bulls achieved a scrotal circumference of 25 cm. Semen samples will be assessed for morphological evidence of maturity (percentage live sperm and presence of proximal droplets).

Pedigree and sire information will be collected and hair samples taken from each bull for genomic testing (Clarifide, Zoetis) to determine the Australian Breeding Values for each bull. The resulting values will then be analysed for potential relationships between scrotal circumference and daughter fertility.

Results: Preliminary results show positive correlations between growth and scrotal circumference for both groups of bulls. There may be some differences between breeds, however, data collection continues and full analysis is yet to be obtained.

Genomics information is yet to be assessed; however areas of interest include the potential relationship between Australian Breeding Values, particularly scrotal circumference and daughter fertility. There may be potential value in adding genomics evaluations to the standard BBSE for natural service sires.

Conclusions: The BBSE is an increasingly important tool for veterinarians and producers in assessing the fertility risk of natural service sires in the dairy industry. In collating more information on dairy breed sires we hope to enable this decision making tool, resulting in better fertility and improved stock selection both for producers and the industry at large.

Comments: My submission could be considered 'young stock' or 'dairy herd health management' as well as 'reproduction- dairy'.

Comparison Of A Novel Ovsynch Program Utilising Early Pregnancy Diagnosis As A Measure Of Performance In Australian Pasture Based Dairy Herds

Johanna Rheinberger^{1,2*} David Colson² David Beggs¹ Peter Mansell¹ Robert Rheinberger³ Michael Pyman¹

¹University of Melbourne, Melbourne, ²The Vet Group, Allansford, ³Ironmines Vet Clinic, Mittagong, Australia

Objectives: This study aims to compare a new ovsynch (ovulation synchronisation) program that incorporates a second prostaglandin injection (PGF_{2α}) with an existing ovsynch program to determine whether or not an improvement in conception rate can be achieved in pasture based, seasonal herds in Australia. This study will also examine the progesterone levels of a subset of cattle as an indication of whether ovulation is occurring at the time of insemination in both groups. After pregnancy diagnosis has occurred, any animal that was not pregnant and was not detected in oestrus post insemination will be examined retrospectively and available data analysed.

Materials and Methods: Two experiments were performed using two groups of predominantly Holstein-Friesian cows which were chosen using the odd and even numbers on their ear tags to randomly assign them to the two groups. The cows used were both primiparous and multiparous lactating animals. These animals were sourced from several farms in South West Victoria, Australia. Group 1 was given the original OVSYNCH program which incorporated a GnRH injection at day 0, one PGF_{2α} injection at day 7 and a GnRH injection 56 hours later followed by fixed time artificial insemination 16-20 hours after the final GnRH. Group 2 was given the modified ovsynch program which incorporated a second PGF_{2α} injection on day 8. A subset of animals, randomly chosen based on their ear tags from both groups, were subject to two blood tests on day 7 and 10, to measure progesterone levels. This will be an indication of whether the animals ovulated at the time of AI and determine if there was a significant difference between the two groups of animals. All animals were submitted for early pregnancy diagnosis between day 35 and 40 after AI, using linear ultrasound, and the results recorded. The Data will be analysed to determine whether there was a statistically significant difference in pregnancy rate between the two ovsynch programs and if there was an improvement in the conception rate using the modified approach.

Results: This experiment is not yet complete and will involve about 3000 cows (n = 1500 in each group). The decision to use this number of cows has been validated by using the chi square test. At the time of presentation, the experiment will be well advanced with several sets of results that will give an indication of the likely outcome. Early results that have been analysed are indicative of an improvement in conception rate when using the modified ovulation synchronisation program that incorporates a second prostaglandin injection.

Conclusions: This experiment is not yet complete and will involve about 3000 cows (n=1500 in each group). At the time of the presentation, the experiment will be well advanced with several sets of results that will give an indication of the likely outcome.

P03-003-195

Association between udder health and the calving-to-first service and calving-to-conception intervals in Holstein and Normande dairy cows

Nestor Alonso Villa Arcila^{1*} Marcelo Ratto² Juan C. Rodríguez³ Javier Sánchez⁴ Alejandro Ceballos¹

¹Dept. of Agric. Sciences, Universidad de Caldas, Manizales, Colombia, ²Ross University School of Veterinary Medicine, Ross University School of Veterinary Medicine, Basseterre, Saint Kitts and Nevis, ³Department of Pathology and Microbiology, ⁴Health Management, University of Prince Edward Island, Charlottetown, Canada

Objectives: The aim of this study was to determine the effect of the infection status of the udder in the first month of lactation on the calving-to-first service (CFSI) and the calving-to-conception (CCI) intervals in Holstein and Normande dairy cows under grazing systems.

Materials and Methods: An observational study was carried out in five dairy herds in Caldas, Colombia. A convenience sampling was used to select 208 cows, 151 were Holstein and 57 Normande, 165 cows were multiparous, and 43 were primiparous. Cows were on a grazing system plus supplementation with grains according to milk yield. Mineral mixes and water were available ad libitum. Composite milk samples were collected on a weekly basis, starting in the first wk after calving up to four wk after calving. One sample was used to determine the somatic cell count (SCC), while the other one was used for culture only if SCC was above 100.000 cells/mL in primiparous cows, and 200.000 cells/ml in multiparous cows. An intramammary infection (IMI) was declared when the SCC arithmetic mean in the four wk after calving was higher than the cut-offs, and at least one culture was positive for a mastitis-causing pathogen. Information on the intervals from calving to first service and calving to conception was recorded.

The association between an IMI and the reproductive parameters was graphically evaluated using Kaplan-Meier survival graphs. Survival curves were compared using a Wilcoxon, Tarone-Ware, and Peto-Peto-Prentice tests. Further, parametric analysis were used to evaluate the fixed effects of herd, breed, parity, and milk yield. Analyses were performed using the commands `stset` and `streg` of Stata® 14.0 (StataCorp, College Station, TX, USA).

Results: The breeding period started 40 d after calving, as all herds followed a voluntary waiting period before the first service. Cows were followed up for 300 d after calving, any information about the failure of interest (conception) beyond this period was considered censored. According to the Kaplan-Meier survival graphs, the median survival time for CFSI was 75 d no differences were found according to IMI (P > 0.05). The survival graph for CCI showed a lower risk of conception in cows IMI (P < 0.05). Parametric models, exponential and Weibull, showed no effect of independent variables: breed, parity, average milk yield, and the interaction between IMI around calving and time (P > 0.05). Subsequently, the single effect of IMIs and time was evaluated. Both parametric models showed a significant effect of IMI in the first month after calving on the risk of conception in the follow-up period. At any time after calving, cows with IMI had 0.67 [=exp(-0.403)] times lower

risk of conception compared with negative cows. The predicted median from CC interval was 111 d and 135 d for cows without and with IMI, respectively. The shape parameter (p) of the Weibull time distribution was greater than one, indicating that the hazard of conception in both groups of cows was not constant and increased with time after calving.

Conclusions: The presence of IMIs in the first month after calving was associated with longer intervals from calving-to-conception; therefore, a cow will need a larger number of days become pregnant. Although cow-level factors did not affect the indices studied, there was an effect of the overall herd management that should not be dismissed as a potential explanation for the results

Reproduction: (Dairy)

P03-003-197

Key factors influencing reproductive performance in seasonal-calving dairy herds

Elizabeth A. Lane¹; Patrick T. Kelly²; Mark A. Crowe³; Simon J. More³; Mary Herlihy²; Doreen Corridan²

¹Department of Agriculture, Food and the Marine, Backweston Campus, Celbridge, County Kildare, ²Munster Cattle Breeding Group, Mallow, County Cork, ³UCD School of Veterinary Medicine, University College Dublin, Dublin 4, Ireland

Objectives: Economic sustainability of seasonal calving dairy herds is dependent on fertility performance. In Ireland, our reliance on grass-based management systems, dictates that the vast proportion of dairy cows must calve within a pre-defined calving season to maximize economic output, to optimise milk production from grass, and crucially maximise postpartum periods for re-breeding. Breed, age, milk production, energy balance, and inter-current disease have all been demonstrated to influence dairy cow fertility. The aim was to evaluate the relative importance of herd and management factors on reproductive performance in seasonal calving dairy herds.

Materials and Methods: Breeding data were collected from 93 seasonal-calving Irish dairy farms to determine the relative importance of herd and management factors on reproductive performance, described in terms of two binary outcome variables: achieving (or not) a 65 % six-week pregnancy rate and a 15 % end of season not pregnant (empty) rate. Individual cow data were collapsed to attain herd level data pertaining to herd size, age, economic breeding indices, oestrous detection efficiency and accuracy, and calving pattern. Separate models were developed for each outcome variable, using backward-stepwise multivariable logistic regression analysis. The fit of the statistical models was evaluated using the Hosmer and Lemeshow goodness-of-fit test.

Results: The mean (\pm SEM) 24, 48 and 72 day submission rates were 73 (\pm 2.2), 87 (\pm 2.1) and 93 (\pm 1.8) %. Mean calving to conception interval was 97 days varying from 80 to 174 days for individual farms; suggestive that the predicted calving to calving interval was 377 days (range 362 to 414 days). The six-week and twelve-week pregnancy rates were 54 (\pm 1.7) and 72 (\pm 1.7) %, respectively. Concerning the six-week pregnancy rate: herds classified as having a lowered proportion (mean 44 %) of early calving cows were 28 (confidence interval; CI; 4.5 to 177) times less likely ($P = 0.003$) to achieve a high six-week pregnancy rate (> 65 %) compared with herds classified as having a high proportion of early calving cows (mean 58 % cows classified as early calvers). Herds with lowered oestrous detection efficiency were 6 (CI 1.2 to 28) times less likely to achieve a high (> 65 %) pregnancy rate compared with herds categorised as having good oestrous detection efficiency. Concerning

the empty rate: the mean empty rate was 19 % (range 0 to 41 %) for all farms. Herd size was the single factor associated with empty rate ($P < 0.01$). Only 13 and 16 % of medium and large herds, respectively, achieved an empty rate of less than 15 %, compared with 46 % in the smaller herds.

Conclusions: The existing calving pattern and oestrous detection efficiency were the greatest determinants of fertility in seasonal-calving herds. Management strategies aimed at improving oestrous detection and the calving pattern are essential and strategies must be employed to deal with late calving cows. Management of replacements to ensure early calving is key. The high empty rate is of concern as it severely limits a farm's ability to cull animals for reasons other than fertility. Larger herds were more at risk of not achieving high overall pregnancy rate. Greater attention is required in expanding herds to ensure fertility is not compromised.

P03-003-198

Efficacy of nonsteroidal antiinflammatory drugs for the treatment of acute puerperal metritis in dairy cows

Alina Pohl¹; Sandra Bertulat¹; Onno Burfeind²; Wolfgang Heuwieser¹

¹Freie Universität Berlin, Clinic of Animal Reproduction, Berlin, ²Chamber of agriculture Schleswig-Holstein, LVZ Futterkamp, Blekendorf, Germany

Objectives: Acute puerperal metritis (APM) is a potentially life threatening, painful disease and is often treated with third-generation cephalosporins. An increasing antibiotic resistance is well documented and associated with decreasing clinical efficacy, animal welfare and economic consequences. Hence, there is the need to evaluate alternative therapies to antibiotics. Nonsteroidal anti-inflammatory drugs are frequently used as supportive treatment in addition to antibiotics and high self cure rates of APM are described. Therefore, the objective of this study was to compare the efficacies of ketoprofen and ceftiofur for the treatment of APM.

Materials and Methods: Between June 2013 and February 2015 a total of 610 dairy cows from 6 farms in Germany were enrolled. Inclusion criteria was a rectal temperature (RT) ≥ 39.5 °C and a reddish-brown fetid vaginal discharge within the first 10 DIM. Cows meeting the inclusion criteria were randomly allocated to treatment with ketoprofen (3 mg/kg of body weight, $n = 300$) or treatment with ceftiofur (1 mg/kg of body weight, $n = 310$), both administered on 3 consecutive days. Rectal temperature was recorded daily for a period of 7 days after enrollment. Cows that showed RT ≥ 39.5 °C on day 4 to 7 after inclusion received an extended treatment (extT) with ceftiofur for 3 (ketoprofen group) or 2 (ceftiofur group) more days. Between 21 and 40 DIM cows were examined with the metricheck device and vaginal discharge was categorized on a 5-point scale according to the presence of pus.

Results: A total of 52 cows (35 from ketoprofen group, 17 from ceftiofur group) were excluded from analysis due to missing protocol compliance ($n = 37$) or concurrent disease ($n = 15$). Cows initially treated with ketoprofen were more likely to have an extT than cows treated with ceftiofur (61% vs 31%, odds ratio 3.47, $P < 0.01$, $n = 558$). Occurrence of purulent vaginal discharge (PVD) was similar for both treatment groups (ketoprofen: 56%, ceftiofur: 53%, $P = 0.64$). However, cows with an extT had 2.12 ($P < 0.01$, $n = 438$) times the odds of PVD than cows without extended treatment. Treatment group did not affect mean

100 DIM milk yield ($P = 0.58$), first artificial insemination (AI) pregnancy risk ($P = 0.25$), time to first AI ($P = 0.65$) and time to pregnancy ($P = 0.56$).

Conclusions: More than half of the cows initially treated with ketoprofen needed an extT with ceftiofur. However, the number of ceftiofur doses administered could almost be cut in half as well without negative effects on the prevalence of PVD, milk yield, and reproductive performance.

Effect of puerperal uterine diseases on histopathological findings and mRNA expression of pro-inflammatory cytokines of the endometrium in dairy cows

Maïke Heppelmann^{1*}Merle Weinert¹Susanne Ulbrich²Anne Brömmling¹Marion Schmicke¹Sabine Merbach³Heinz-Adolf Schoon⁴Martina Hoedemaker¹Heinrich Bollwein⁵

¹Clinic for Cattle, University of Veterinary Medicine Hannover, Hannover, Germany, ²ETH Zürich, Animal Physiology, Institute of Agricultural Sciences, Department of Environmental Systems Science, Zurich, Switzerland, ³Chemical and Veterinary Investigation Office Westphalia, Pathology and Bacteriology, Arnsberg, ⁴Institute of Pathology, Faculty of Veterinary Medicine, University of Leipzig, Leipzig, Germany, ⁵Clinic of Reproductive Medicine, Vetsuisse Faculty, University of Zurich, Zurich, Switzerland

Objectives: The aim of this study was to examine if uterine diseases occurring during the first two weeks after parturition have a long-lasting negative effect on histopathological and molecular parameter of the endometrium in dairy cows.

Materials and Methods: Forty-nine lactating Holstein Friesian cows were divided into two groups, one without (UD-; $n=29$) and one with uterine diseases (UD+; $n=21$), defined as retained fetal membranes and/or metritis. General clinical examination, vaginoscopy, transrectal palpation and transrectal B-Mode sonography were conducted on Days 8, 11, 18, 25 and then every 10 days until Day 65 (Day 0=day of calving). The first endometrial sampling (ES1; swab and biopsy) was done during estrus around Day 42 and the second ES (ES2) during the estrus after synchronisation (cloprostenol between Days 55 and 60 and GnRH 2 days later). Swabs were used for aerobic bacterial examination. Endometrial biopsy samples were evaluated histopathologically; inflammation was categorized as acute purulent, chronic purulent and chronic non purulent endometritis. Gene expression of pro-inflammatory cytokine (interleukin (IL)1 α , IL1 β , IL6 and tumor necrosis factor (TNF) α) in the endometrium were determined by quantitative reverse transcriptase PCR.

Results: Cows of groups UD- and UD+ showed no differences ($P>0.05$) in the frequency of histopathological inflammatory alterations of the endometrium and in the prevalence of positive bacteriological cultures. However, UD+ cows more often had a chronic purulent endometritis (ES1; $P=0.07$) and an angiosclerosis (ES2; $P\leq 0.05$) than UD- cows. Endometrial gene expression of pro-inflammatory cytokine IL1 α (ES2), IL1 β (ES2) and TNF α (ES1 and ES2) were higher ($P\leq 0.05$) in cows of the UD+ group than in the UD- group.

Conclusions: In conclusion, puerperal uterine diseases in cows affect the endometrium not only during the puerperium, but also during the postpuerperal period by inducing histopathological alterations as well as a rise in gene expression of pro-inflammatory cytokines.

Dynamics of pregnancy loss in Jersey, Holstein, and Jersey x Holstein crossbred cows in large multibreed dairy herds

Pablo Pinedo^{1,2*}Pedro Melendez³Angela Daniels⁴Sushil Paudyal⁵Roney S. Ramos⁶

¹Department of Animal Science, Colorado State University, Fort Collins, CO 80525, ²Texas A&M AgriLife Research, Texas A&M AgriLife Research, Amarillo TX, ³College of Veterinary Medicine, University of Missouri, Columbia, ⁴Circle H Animal Health LLC, Dalhart, TX, ⁵West Texas A&M University, Canyon, TX, United States, ⁶School of Veterinary Medicine and Animal Science, University of São Paulo, Pirassununga, SP, Brazil

Objectives: The objective was to analyze the dynamics of pregnancy losses (PL) for the genetic groups Jerseys (JE), Holsteins (HO), and Jersey x Holstein crossbreds (JH), considering parity, disease occurrence, year and season in large multibreed dairy herds in Texas, USA.

Materials and Methods: The study analyzed lactation records from 3 dairy herds located in NW Texas, USA. Herds included Holstein, Jersey, and Holstein x Jersey crossbreds. A total of 25,840 breeding records of cows calving between January 2005 and December 2011 were available. Data were extracted from on-farm software and consisted of cow identification number, breed, calving date, parity, date of breeding and sire, pregnancy check date and outcome, herd code, and recorded health disorders and date. Early pregnancy diagnosis (around 35d) was performed by one of the authors (farm veterinarian) by transrectal ultrasonography and pregnancy reconfirmation was done by palpation per rectum. A diagnosis of pregnancy loss was made when a cow that was determined pregnant was subsequently diagnosed as non-pregnant or received a subsequent breeding. Data were analyzed by logistic regression and explanatory variables included genetic group, disease occurrence, parity, year, season, and herd.

Results: Pregnancy loss for the overall period was 8.9%. Percentages of pregnancy loss per year were 16.8,

12.8, 15.8, 10.9, 6.3, 9.1, and 4.2 for 2005, 2006, 2007, 2008, 2009, 2010, and 2011, respectively. Regarding genetic group, values for PL were 10.1, 7.3, and 4.9 for HO, JE, and HJ, respectively. The odds of PL were significantly higher for HO ([95%CI] = 2.16 [1.62-2.86]) and JE ([95%CI] = 2.07 [1.27-3.36]) cows compared with HJ crossbred. Cows that had a disease event during lactation had a PL of 11.2% compared to 8.4% in healthy cows. The odds of PL were significantly higher for cows with at least one disease event ([95%CI] = 1.34 [1.20-1.48]) compared with healthy cows. Pregnancy loss was lowest for breedings in fall (7.77%) and highest for breedings in spring (10.2%).

Conclusions: The level of pregnancy loss in this population of dairy cattle decreased during the study period, was associated with occurrence of disease, and was significantly lower in the HJ crossbred than in the pure breeds.

Randomized clinical trial of intrauterine cephalosporin in dairy cows for the treatment of purulent vaginal discharge and cytological endometritis

Jocelyn Dubuc^{1,*}, José Denis-Robichaud²

¹Faculté de médecine vétérinaire, Université de Montréal, Saint-Hyacinthe, Québec, J2S 7C6, ²Department of Population Medicine, University of Guelph, Guelph, ON, N1G 2W1, Canada

Objectives: Purulent vaginal discharge (PVD) and cytological endometritis (ENDO) diagnosed by cytobrush are associated with detrimental impact of reproductive performance of dairy cows. Research suggested that ENDO could be diagnosed using a leukocyte esterase colorimetric test (EST). The efficacy of intrauterine cephalosporin for treating PVD is known but its efficacy for treating ENDO diagnosed by cytobrush or by EST remains unclear. The objectives of this study were to validate ENDO diagnostic approaches (cytobrush and EST), and to quantify the impact of cephalosporin on the reproduction at first service of postpartum dairy cows affected by these diseases.

Materials and Methods: A total of 2259 Holstein cows from 28 commercial dairy herds were enrolled a randomized clinical trial. At 35 (\pm 7) days in milk (DIM), cows were diagnosed for PVD (purulent vaginal discharge or worse) and ENDO (\geq 6% polymorphonuclear cells using the cytobrush technique or at least small amounts of leukocytes using the EST). Regardless of reproductive tract disease status, cows were randomly assigned to receive an intrauterine cephalosporin infusion or no treatment. Statistical analyses were conducted using multivariable mixed logistic regression models adjusted for confounders and herd clustering effect.

Results: Prevalences of PVD, ENDO (cytobrush) and ENDO (EST) were 19, 35, and 49 %, respectively. Intrauterine cephalosporin treatment was associated with an increased first service pregnancy risk in cows diagnosed with PVD (no treatment: 15.4%; treatment: 31.4%) and ENDO (cytobrush: no treatment: 16.2%, treatment: 24.4%; EST: no treatment: 15.8%; treatment: 25.1%), but not in cows unaffected by any form of reproductive tract disease (no treatment: 34.8%; treatment: 32.6%). Kappa value (agreement) between the cytobrush technique and EST was 0.43.

Conclusions: Overall, an intrauterine infusion of cephalosporin improved first service pregnancy risk in cows with PVD and ENDO. Although, the cytobrush and EST diagnostic approaches did not provide the same information for ENDO diagnosis, they were both associated with a positive benefit on first service pregnancy risk when cows were treated with intrauterine cephalosporin.

Investigations of mammary and uterine blood flow in relation to milk yield, postpartum disease and pregnancy result in dairy cows

Kathrin Herzog^{1,*}, Michael Lietzau², Martina Hoedemaker², Heidemaria Berger²

¹Lower Saxony State Office for Consumer Protection and Food Safety, Oldenburg, Germany, Oldenburg, ²Clinic for Cattle, University of Veterinary Medicine Hannover, Hannover, Germany

Objectives: Milk yield of dairy cows has increased continuously during the last few decades while fertility parameters such as conception rate have declined. The objective of this study was the determination of blood flow variables of dairy cows in the uterine arteries and the pudendoepigastric trunks, which supply the mammary gland. These variables were related to the occurrence of uterine diseases, milk yield, and pregnancy result.

Materials and Methods: To achieve this, 119 multiparous German Holstein cows were examined transrectally using color Doppler sonography once during the dry period before parturition and on Days 7, 14, 28, 42, 56, 66, 76, 86 and 96 postpartum (pp). Milk yield and postpartum diseases were documented. After day 43, cows were inseminated during spontaneous estrous cycles or they underwent an OvSynch protocol and fixed-time AI. Cows that were not bred by day 56 were examined ultrasonographically every 10 d. Cows were examined ultrasonographically for pregnancy 26 d after AI, and in pregnant cows the vitality of the embryo was confirmed on day 42. Examinations were discontinued on day 42 when a cow was confirmed pregnant or on day 150 in cows that failed to conceive.

Results: Mean daily milk yield of all cows for the first 42 days was 37.7 ± 6.2 kg (mean \pm SD; min. 15.2, max 52.4 kg). Milk yield was correlated with BFV in the pudendoepigastric trunks on examination Days 7 to 96 pp with the exception of Day 76 ($P < 0.05$), and with TAMV on Days 7 and 14 pp ($P < 0.05$). The PI was greater in the left trunk ($P < 0.05$).

Depending on the mean daily milk yield in the first 42 days pp, 57 cows classified as high-milk-yielding (HMY) having a mean daily production of 42.7 ± 2.7 kg, and 62 cows classified as low-milk-yielding (LMY) had a mean production of 33.1 ± 4.8 kg.

On day 150 pp, 75 of 119 cows (63 %) were pregnant. Pregnancy result did not differ between LMY (43 of 62 pregnant, 69%) and HMY cows (32 of 57 pregnant, 56%; $P > 0.05$).

Mammary blood flow volume (BFV) was greater in pregnant HMY cows than in pregnant LMY cows on days 7, 14, 28 and 42 ($P < 0.05$), but time-averaged maximum velocity (TAMV) and pulsatility index (PI) did not differ between the two groups. Mammary BFV did not differ between open HMY and LMY cows ($P > 0.05$). Uterine blood flow did not differ between HMY and LMY cows ($P > 0.05$). Mammary and uterine blood flow did not differ between pregnant and open HMY cows and between pregnant and open LMY cows ($P > 0.05$). Likewise, mammary and uterine blood flow did not differ between pregnant and open cows of both production levels combined ($P > 0.05$).

Cows with retained fetal membranes (RFM) or metritis had a higher BFV and TAMV and a lower PI in the uterine arteries on Days 7, 14 and 28 pp ($P < 0.05$).

Conclusions: Milk yield did not affect pregnancy result and was not related to uterine perfusion. Increased uterine perfusion in cows with RFM and metritis may be due to increased uterine size attributable to delayed involution. High mammary perfusion in high-yielding cows is due to an increased demand for nutrients and oxygen. Color Doppler sonography is useful for the investigation of uterine and mammary perfusion in the context of puerperal disease and milk yield.

The effect of hypocalcemia and two different calcium treatment forms on uterine contractility in early postpartum cows

Arpad Csaba Bajcsy^{1,2,*}Gergő Kürtös¹Laura Zámbo¹János Tibold³István Mádl³Ottó Szenci^{1,2}

¹Department and Clinic for Production Animals, Szent Istvan University, Faculty of Veterinary Science, ²Research Group of Clinic for Large Animals, Hungarian Academy of Science, Üllő, ³Agroprodukt Agrar Co., Pápa, Hungary

Objectives: Aged lactating cows are exposed to hypocalcemia around calving, which may cause a declined smooth muscle activity of the myometrium. This may contribute to the reduced expulsion of the uterine content, thereby negatively influencing the process of involution. Various calcium treatment forms are used in dairy practice, but the exact effects of such products on puerperal uterine contractility are not exactly known. The aim of this study was to determine the effect of subclinical hypocalcemia and two forms (intravenous and per os) of calcium treatment on uterine contractility early postpartum.

Materials and Methods: Myometrial contractions of normocalcemic (n=14; blood Ca²⁺>1.06 mmol/l) and hypocalcemic cows (n=38; blood Ca²⁺<1.06 mmol/l) at a large-scale dairy cattle farm were examined using an open tip catheter system, that is suitable for measuring intrauterine pressure (IUP) changes. The first recording started 14-17 hours after calving and further three observations were performed in 12 hours intervals from the beginning of the previous session. Hypocalcemic cows were randomly treated either with intravenous (n=10; Cofacalcium inj. A.U.V., Coophavet), or oral (n=10; ReCovin Calcium paste, Kruuse) calcium 1 hour after the beginning of the first recording once. Data of intrauterine pressure changes were collected from the previously gravid uterine horn, and after amplification and digitalisation they were analyzed using a semiautomatic, operator-made software (LabVIEW 5.0, National Instruments). Contraction frequency, amplitude, duration, mean and total area under the pressure curves were calculated. Coccygeal blood was withdrawn at the beginning of the first and at the end of all recordings and Ca²⁺ was measured using a portable blood gas and electrolyte analyzer on site (ABL-77, Radiometer). Correlation analysis and two-sample t-tests were used for statistical analysis.

Results: Positive correlation was found between blood Ca²⁺ concentration and the frequency of myometrial contractions 14-17 hours postpartum (r=0.61; P<0.001). Cows with retained fetal membranes (n=14) had significantly higher frequencies than non-retained cows (P<0.001). Cows treated with a single dose of oral calcium did not show any significant differences as related to the untreated control cows in terms of uterine contractility during the first measurement, but their mean contraction frequency was significantly (P<0.05) higher during the second. Six cows that received intravenous calcium showed a marked increase (238%) in contractility during the first hour after the infusion. However, in 4 cows such an increase could not be observed.

Conclusions: Subclinical hypocalcaemia had a negative effect on uterine contractility. In most cases intravenous calcium treatment was very effective to improve myometrial activity. Oral calcium supplementation did not cause such a marked elevation of uterine mechanical activity, but it might have a possible beneficial long-term effect.

The relationship between fatty acid profiles in milk identified by fourier transform infrared spectroscopy and onset of luteal activity in dairy cows

Adam Martin^{1,*}Nils Kristian Afseth²Achim Kohler³Åshild Randby⁴Margrete Eknæs⁴Andres Waldmann⁵Guro Dørum⁶Ingrid Måge²Olav Reksen¹

¹Department of Production Animal Clinical Sciences, Norwegian University of Life Sciences, Oslo, ²Nofima - Food Research Institute, ³Department of Mathematical Sciences and Technology, ⁴Department of Animal and Aquacultural Sciences, Norwegian University of Life Sciences, Ås, Norway, ⁵Department of Production Animal Clinical Sciences, Estonian University of Life Sciences, Tartu, Estonia, ⁶Department of Chemistry, Biotechnology and Food Science, Norwegian University of Life Sciences, Ås, Norway

Objectives: Milk components represent information on the metabolic state of the milking cow. Previous work has shown milk fat:protein ratios in milk to be unreliable predictors of reproductive performance (1) and direct measures of progesterone are expensive. Fourier transform infrared spectroscopy (FTIR) has previously been used for online measurement of milk components in the wet phase (2). Drying the milk sample before analysis decreases component detection limits and improves estimate accuracy (3). This study aimed to use dry phase to measure different components of the milk fat fraction and to compare these to onset of luteal activity (OLA).

Materials and Methods: Morning milk samples were collected thrice weekly (Monday, Wednesday, Friday) for the first 10 weeks in milk (WIM) from 87 lactations in 73 healthy Norwegian Red cows over two winter housing seasons. These samples had bronopol added to them before being frozen, thawed, and analysed by enzyme linked immunoassay to determine progesterone concentration and the proportions of the milk fatty acids which were C4:0, C14:0, C16:0, C18:0, and C18:1cis9 using dry film FTIR (3), and averaged by WIM. OLA was defined as the first day that milk progesterone concentrations were >3ng/ml for two successive measurements, the study population was categorised as early (n=47) or late (n=40) OLA, using the median value of 21 DIM as the cut off. Further milk samples were collected 6 times weekly, from morning and afternoon milkings, these were pooled by WIM and one proportional sample was analysed fresh for fat, protein and lactose content, using infrared spectrography. Feed intakes, bodyweight, milk content and yield were recorded. These data were used to calculate daily energy balance (EB) in 42 lactations before they were averaged by WIM at the cow level. Relationships were explored for each WIM using the student's t test (EB), or logistic regression (Early OLA vs. late OLA).

Results: Higher proportions of medium chained fatty acids (C14:0 and C16:0) were found in the early, than in the late OLA group from WIM 1 until WIM 7 (weekly p value always <0.05). In WIM 4, a lower milk fatty acid proportion of C16:0 predicted late OLA with 74% sensitivity and 80% specificity. The proportion fatty acids that were long chained (C18:0 and C18:1cis9) was consistently lower in the milk of the early OLA group and the difference was greatest in WIM 4 and 5. A higher proportion of C18:1cis9 was seen in the milk fatty acids of the late OLA compared to the early OLA group from WIM 1 until WIM 5 (all weekly p-values <0,05). Animals experiencing late OLA had a more negative EB in WIM 1, 3, 4, and 5 (p-values < 0.05) than those in the early group. The greatest differences were in WIM 3 and 4. No relationship was seen between OLA and the content of either protein or fat in milk, or between OLA and the milk fat:protein ratio. The differences in milk fatty acid concentrations between the two groups were most likely the result of differences in energy balance between the two groups (4).

Conclusions: This study showed that OLA is related to specific milk fatty acid concentrations. The relationships occur from WIM 1. When OLA is dichotomised as early or late, univariate analysis found prediction accuracy to be highest in WIM 4. This study also showed that dry film FTIR performed on previously frozen milk samples can determine milk fatty acid composition.

P03-003-205

The effects of building design on hazard of first service in Norwegian dairy cows

Adam Martin¹, Camilla Kielland², Sindre Nelson², Olav Østerås³

¹Department of Production Animal Clinical Sciences, * Norwegian University of Life Sciences, ²Department of Production Animal Clinical Sciences, Norwegian University of Life Sciences, Oslo, ³Norwegian Cattle Health Services and TINE Extension Services, Ås, Norway

Objectives: Legislation passed in Norway bans the use of cattle tie stalls from 2024. Dairy producers with these facilities must build cubicle sheds or cease cattle production by 2024. Therefore, there is a requirement for information about how building design influences cattle health and production so that building designs can be optimized and returns from capital investments maximized. This study aims to investigate the effect of specific environmental factors such as herd size, stocking density, floor type, and building layout on calving to first service in Norwegian dairy cattle.

Materials and Methods: This study was part of a larger descriptive and cross-sectional project on freestall housing in Norwegian dairy herds. Inclusion criteria for the study were: farmers willingness to participate, herd size > 20 standardized cow years (based on the year 2005), barns built between 1995 and 2005, and the presence of free stalls. All 232 farms that fulfilled the inclusion criteria were included in the study. The herds were visited once during the indoor housing period between September 2006 and June 2007 by trained technicians. The technicians recorded: type of flooring (in the alleys and feeding area), Free accessible area (alleyways, freestalls, feeding areas), number of alleyways, number of dead-ending alleyways, and the total number of freestalls present on the farm for the adult cows. Herd level data were gathered from NDHRS database these included average herd milk yield per cow year (total milk delivered from the farm annually / cow years), and herd size (in cow years). Lactation level data were also extracted from this database. The final dataset contained data on 38,436 calvings and 27,127 services. Time to event data were analyzed using Cox proportional hazard modeling techniques. The explanatory variables were tested in univariate cox-proportional hazard models, a frailty term for the variable farm was included in the model. A crude hazard ratio for each explanatory variable was generated. Explanatory variables with a univariate P-value of <0.10 were included in a forward stepwise procedure to build a multivariable model.

Results: Univariate cox proportional hazard analyses showed that herd size and milk yield were positively associated with HFS. Total free accessible area (FAA) and FAA available per cow year were positively associated with the HFS, as was the number of freestalls available per cow. Cows housed on slatted floors had a lower HFS than those housed on solid floors. Conversely, cows housed on rubber floors had a higher HFS than cows on concrete floors. Dead-ending alleyways reduced the hazard of AI after calving. A multivariable cox proportional hazards model, accounting for herd management by including a frailty term for herd, showed relationships between hazard of postpartum service and explanatory variables. Animals in herds with more than 50 cows had a higher HFS (Hazard ratio (HR) 3.0) compared to those in smaller herds. The HFS was also higher (HR 4.3) if there was more than 8.8 M² of space available per cow year compared to herds in which animals had less space. HFS after calving increased with parity (parity 2 HR 0.5, parity ≥ 3 HR 1.7), and was reduced if a lactation began with dystocia (HR 0.82) or was a breed other than Norwegian Red (HR 0.2). The frailty term, herd, was large and highly significant indicating a significant proportion of the variation resides at herd level. The hazard of first insemination decreased with time for all predictive variables, except dystocia.

Conclusions: This study shows that providing adequate environmental conditions for estrus behavior is imperative for reproductive efficiency, also after herd management factors and time from calving have been accounted for. Thus optimizing building design for reproductive efficiency is of significant importance when constructing new cattle housing.

Comparative metagenomics of the bovine endometritic and healthy uterine microbiota and its predicted functional diversity by shotgun sequencing

Marcela Bicalho¹, Rodrigo Bicalho¹

¹Cornell University, Ithaca, United States

Objectives: The aim of this study was to characterize by the first time, using metagenomics shotgun DNA sequencing, the intrauterine microbial population and its predicted functional diversity from healthy cows and cows affected with endometritis. We expected to identify relationships of certain microbial genes with postpartum uterine health.

Materials and Methods: In total, 20 Holstein dairy cows at 25-35 days postpartum from a single farm located near Ithaca, NY, were enrolled in the study. Enrolling period was from June 7th, 2014, to June 14th, 2014. Endometritis diagnosis was diagnosed by retrieving and scoring vaginal discharge using the Metricheck[®] device. Intrauterine samples for microbiological analysis were taken by cytobrush technique from the 20 cows, 8 cows diagnosed with endometritis and 12 healthy cows. After sampling, the cytobrushes were transferred to a DNA/RNA free 2 ml microcentrifuge tube containing 1.5 mL of DNA/RNA free water. Following vortex, cytobrushes were removed from tubes and the suspension was centrifuged. Pellet was used for extraction of total DNA using PowerSoil DNA Isolation Kit. After normalization the samples were used as an input to the Nextera XT DNA Sample Prep Kit. Pair-end sequencing was performed using the MiSeq Reagent Kit v3 through the Illumina MiSeq platform. Additionally, total number of bacterial 16S rDNA copies in uterine samples was detected by Real-Time PCR.

Sequences were uploaded to the MG-RAST pipeline to determine relative abundance of the microbiota and to predict functional abundance. The non-redundant multi-source protein annotation database (M5NR) and SEED were the annotation source used.

Results: Uterine samples sequences were assigned to Bacteroidetes, Proteobacteria, Firmicutes, Fusobacteria, Actinobacteria, and Spirochaetes. Fusobacteria was almost absent in healthy uterine microbiota, representing about 0.5% of the population. The most abundant genera within Fusobacteria phylum (Propionigenium, Ilyobacter and Fusobacterium) were significantly more abundant in endometritic cows. Genus Trueperella was absent in healthy uteri. E. coli were the most abundant species in both microbiotas, but did not show statistical difference. Resistance to antibiotic and toxic compounds (RATC) was the predominant subsystem identified in the virulence, disease, and defense system (greater than 50%) for both microbiotas. Multidrug resistance efflux pumps were the highest category identified in RATC subsystem, followed by resistance to fluoroquinolones, copper homeostasis and cobalt-zinc-cadmium resistance. Toxins were unique to endometritic microbiota and Cytolethal distending toxins were predominant. Antibacterial peptides were restrictedly found in healthy microbiota and dominated by tolerance to colicin E2. Capsular and extracellular polysaccharides genes, LPS assembly and Lipid A biosynthesis were higher in healthy microbiota. When Lipid A modification was predicted, it was present only in endometritic samples. Bacterial responses to DNA damage and environment stress were more abundant in healthy microbiota. No difference was observed in total bacterial load between microbiotas.

Conclusions: The study provides a deep insight into uterine microbial community and its dynamics. Bacteria in endometritic and healthy uteri did not show abrupt variations. A microbial core is determinant to define health and disease. Species intrinsic factors may be more relevant to the development of disease than abundance. The prediction of the functional diversity of endometritic and healthy cows may serve to identify unknown etiological agents and virulence factors that contribute to disease, grant therapy development and prevention. Our findings suggest that the endometritic microbiome harbors unique functions that deserve further investigation.

P03-003-208

Comparison Of Ovsynch And Trans-Rectal Palpation As A Treatment For Anestrus In Israeli Dairy Farms

Tamir Goshen¹; Tal Raz¹

¹The Koret Veterinary school, Hebrew University, Rehovot, Israel

Objectives: Dairy farms not applying timed artificial insemination reproduction programs rely on estrus detection for managing herd reproduction. As dairy producer's numbers are declining while the average farm size grows worldwide, automated estrus detection systems are becoming more available. This fact, combined with growing interest in reproductive programs with minimal pharmacological intervention due to public concerns about food safety, present a need for an efficient focused anestrus treatments. The purpose of the presented study is to compare the efficacy of OVSYNCH and ovarian palpation as a treatment for anestrus field cases.

Materials and Methods: The presented study is a multi-centered, randomized, controlled trial designed as a prospective cohort study. The

study was conducted on lactating cows that were submitted for anestrus examination between May 2010 and May 2011 in four commercial Israeli dairy herds consisting of 250 to 600 Israeli Holstein cows.

Control cows not detected in estrus were examined by the attending veterinarian using Trans-rectal palpation and were treated according to the findings on the ovaries. If a corpus luteum (CL) larger than 20 mm in diameter was diagnosed, the cow was treated with a PGF_{2α} analog; 500 µg Cloprostenol Sodium. If a CL was not diagnosed in two trans rectal palpations week apart, the cow was regarded as acyclic, and was treated by IM injection of GnRH; 200 mg Gonadorelin Acetate. Cows treated with GnRH were re-examined 2 weeks later for the presence of a CL. If an acyclic cow did not develop a CL 3 weeks after GnRH treatment, it was treated with IM injection of 5000IU hCG or with a progesterone intravaginal insert. All cows were artificially inseminated at electronically or visually detected estrus.

Cows allocated to the OVSYNCH treatment group were not examined; instead the OVSYNCH protocol was initiated. OVSYNCH cows that were detected on estrus before the completion of the protocol were submitted for artificial insemination by the AI technician. If not detected in estrus, OVSYNCH cows were AI by the designated date of the OVSYNCH protocol.

Results: 488 cows were included in the study; 299 (61.3%) OVSYNCH and 189 (38.7%) Control. OVSYNCH and control groups differed in only in the proportion of cows calving in the summer ($P < 0.001$). OVSYNCH cows had shorter waiting period compared with control cows (median time to 1st AI 104 and 111 days respectively, $P = 0.003$). The OS cows were inseminated closer to the submission for anestrus examination in comparison to the control group (average time to AI 14 and 18.6 days respectively; $P = 0.043$). At submission to AI, higher proportion of the Control cows were not inseminated, as the AI technician did not find physiological estrus signs (29.6% and 17.7% for Control and OS cows respectively; $P = 0.002$).

Conception rates in July and August differed from the other year months. The study groups did not differ neither in crude 1st AI conception rate (25.4% and 28.4% respectively, $P = 0.464$), nor when controlling for summer inseminations in the multivariate analysis ($OR = 1.164$, $P = 0.478$). The pregnancy rate in the study groups did not differ at 150 DIM, but tended to be higher for OVSYNCH cows at 200 DIM (OR to be empty = 0.721, $P = 0.085$).

The time to conception was analyzed using survival analysis for 3 different time periods: Days empty, 1st AI to conception interval and anestrus examination to conception interval (Effective waste days).

The OS group tended to conceive earlier in the lactation in comparison to the palpated group ($P = 0.082$), but no significant differences were demonstrated between the treatment groups in 1st AI to conception interval and for effective waste days.

Conclusions: Anestrus treatment by the application of the OVSYNCH protocol as a part of anestrus management can be effective substitute of traditional ovarian palpation. In the last decades the emphasis of reproduction management is the herd, not the single cow. The economic efficacy of the implementation of individual treatment of anestrus is questioned. However, the public concerns about food safety and animal husbandry ethics may lead to diminishing consumer acceptance of food manufactured by systematically hormone treated animals.

Conception is all the more reduced that mastitis and subclinical ketosis simultaneously occur around artificial insemination

Ahmad Albaaj¹Didier Raboisson^{1*}Gilles Foucras¹

¹National Veterinary School of Toulouse, Toulouse, France

Objectives: Reproductive performances of dairy cows are recognized as a key parameter for profitability of farms, but they are getting worse continuously in many countries. Many reasons of these changes were proposed, and among others, the health status of cows. Mammary infection and subclinical ketosis (SCK) have been reported to have deleterious impact on conception, but their interactions and dynamics are not fully understood. The objective of this study was to better describe the relationship between reproductive performances and udder health, accounting for the interaction with SCK.

Materials and Methods: Data from the national French dairy milk improvement system and data on the artificial inseminations (AI) from 2007 to 2012 were included. Conception at first or at all AI was explained by (i) the udder health status and (ii) the presence of SCK on the test-days around AI. To define the udder health around AI, somatic cell counts (SCC) were classified as High or Low before and after AI, and transformed into four categories (LL, and LH, HH, HL) relative to various thresholds (from 200,000 to 400,000 cells/mL). SCK around AI was defined thanks to fat and protein contents or to their ratio before or after AI. Among the definitions of SCK there were: (i) fat before AI >45 g/L and protein between 35 and 45g/L, (ii) fat : protein ratio before or after AI >1.5, (iii) protein before AI <30 g/L, (iv) protein before AI <30 g/L and protein after AI <28 g/L.

A mixed binomial model adjusted by the lactation stage, milk yield and parity was applied yearly on the whole population or on subpopulations with or without SCK. Herd was kept as random effect in all models.

Results: The relative risk (RR) of conception were 0.86 (95%CI = 0.84-0.87), 0.98 (95%CI = 0.96-1.00) and 0.85 (95%CI = 0.84-0.86) for LH, HL and HH compared to LL, respectively. The same results were observed for the first AI or all AI, and whatever the SCC threshold used. RR of conception was 0.87 (95%CI = 0.84-0.90) with SCK compared to without. Depending on the SCK definition, the RR varied from 0.86 (95%CI = 0.83-0.89) to 0.90 (95%CI = 0.89-0.91). Altogether, this shows that (i) an increase in SCC around AI or (ii) presence of SCK around AI were both associated with a decrease in the conception rate.

The same results are observed in the subpopulation without SCK. The relationships between SCK and conception on one hand and SCC change and conception on the other hand were not independent. First, when performed on the subpopulation with SCK only, the RR of conception for LH compared to LL cows is decreased to 0.74 (95%CI = 0.84-0.87) instead of 0.86 for the whole population. Second, including the interaction term SCK * class of SCC for the regression on the whole population showed that the reduced risk of conception for LH compared to LL was two times higher in the presence of SCK compared to without SCK. Results were robust, even if minor changes in coefficients were observed between the various years of study.

Conclusions: The present results showed that conception success was reduced by around 15% for cows with high SCC or with an increase of SCC around AI. This association was strengthened by including an indicator of SCK and when models were run only on cows with SCK, showing that the relationship between udder health and conception could

be modulated by metabolic disorders such as negative energy balance. These results are of great interest for herd management. Moreover, they support the idea that a local inflammatory reaction may affect systemic functioning and interact with the physiology of distant organs.

P03-003-210

Sensitivity of 21-day Pregnancy Risk to Stated Voluntary Wait Period: A Simulation Study

Stuart Russell^{1*}

¹Nantwich Farm Vets, Nantwich, United Kingdom

Objectives: 21-d Pregnancy Risk (21-d PR) is used to monitor reproduction in dairy herds with non-seasonal calving patterns. It indicates the percentage of eligible cows which become pregnant in a 21 day period. The calculation requires that a voluntary wait period (VWP) be specified although the standardised version uses a 50-day VWP. A common trend in certain regions is to delay the VWP and use universal synchronisation of first insemination, which achieves both high conception risks to first insemination and exceptional VWP-adjusted 21-d PR. The objective of this study was to investigate the sensitivity of 21-d PR to the VWP specified in calculations.

Materials and Methods: A daily Markov-chain model was designed to simulate fertility in an individual cow and her replacements. This model required three prior probabilities for conception risk; at first timed insemination (1st TAI), to oestrus detection, and to resynchronisation. It also required two inputs for 21-d Oestrus Detection Risk, defined as the percentage of eligible cows which were detected in oestrus in a 21 day period; one for each of the periods before and after 1st TAI. Prior probabilities were formulated after literature review, informed by practical experience. The daily probability of oestrus detection was modified by the pattern of reinsemination from a large dataset. Probabilistic components of the model were repeatedly drawn from Bernoulli distributions using RiskAMP v4.76 (Structured Data LLC, USA). After a burn-in period of 365 days and assuming a uniform initial calving distribution, herd performance was simulated over three years. Back-door Ovsynch, Presynch-Ovsynch with and without oestrus detection before 1st TAI ('cherry-picking'), and Double Ovsynch were investigated. For all protocols, 1st TAI occurred at 76 days postpartum. Where applicable, oestrus detection before 1st TAI began at 50 days postpartum. Annual average 21-d PR were calculated using various specified VWP and eligibility criteria emulating DairyComp 305 (Valley Agricultural Software, USA). Multiple runs were performed with a simulated herd size of 250 to investigate the distribution of 21-d PR for each specified protocol, followed by runs of 10,000 cows to show the sensitivity of 21-d PR to VWP.

Results: 21-d PR had variable sensitivity to the VWP used in calculations, with both a greater numerical and proportional sensitivity either with universal synchronisation of first insemination, or with improved fertility management after first insemination. The difference was greatest where both factors combined, such as for a model of the Double Ovsynch protocol with 25d early resynch and excellent oestrus detection after 1st TAI, which achieved a long-run 33.7% (95% CI: 33.3-34.0%) 21-d PR when calculations used the 76 day VWP, or 24.3% (95% CI: 24.1-24.6%) when calculations used the standard VWP. In contrast, a similar model using Presynch-Ovsynch with cherry picking achieved a long-run 26.9% (95% CI: 26.6-27.2%) 21-d PR when calculations used the 76 day VWP and 24.9% (95% CI: 24.7-25.2%) with the standard VWP. Given that its denominator is 'all eligible cows', 21-d PR is effectively weighted by the

size of each eligible group. With improving 21-d PR, and particularly with universal synchronisation of the first insemination, weighting moves from a broadly linear decline with days postpartum to a broadly logarithmic decline. Distributions of eligible groups and standardised 21-d PR for each protocol will be displayed.

Conclusions: Given the variable sensitivity of 21-d PR to VWP, it should be made clear when calculations use an adjusted VWP. This is particularly important where universal synchronisation of first insemination is practiced, or where excellent management of reinseminations is achieved. The mathematical characteristics of 21-d PR place exponential emphasis on fertility in early lactation with incremental improvements in 21-d PR. Manipulation of VWP in calculations may hide potential for further improvements, depending on regional economics. Expected distributions of 21-d PR using a 50-d standardised VWP may be useful for troubleshooting herd management.

P03-003-211

Using a single measurement of insulin-like growth factor-1 to predict the likelihood of reproductive tract health at day 45 postpartum in dairy cows

Sandra Aungier^{1,*}James Roche²Daniel Ryan³Mark Crowe⁴

¹Veterinary Biosciences, ²University College Dublin, Dublin 4, ³Reprodoc Ltd, Co. Cork, ⁴Animal Husbandry and Production, University College Dublin, Dublin 4, Ireland

Objectives: To determine the relevance of : i) vaginal mucus character score, ii) uterine ultrasound scanning (scan), iii) use of cytobrushing of the uterine body endometrium as methods to evaluate reproductive tract health, and iv) whether a single blood sample for IGF-1 concentration collected in week 3 postpartum (pp) can be used as a predictor of reproductive tract health on day 45 pp.

Materials and Methods: The trial involved a herd of 98 Holstein cows. Blood sampling to monitor IGF-1 concentration in week 3 pp., and weekly evaluation of reproductive tract health pp, using ultrasonography and vaginal mucus scoring, were carried out. Twice weekly milk sampling was used to monitor progesterone and resumption of ovulation pp. (Forde et al., 2011). Lameness was assessed every 2 weeks pp. (Sprecher et al., 1997). After day 21 pp., when a clear vaginal mucus sample and normal uterine scan were obtained on two consecutive weekly analyses a cytology brush sample from the uterine body endometrium was carried out (Kasimanickam et al., 2004). Reproductive tract health was graded on day 45 pp. Indices of health status were defined as: i) normal uterine scan (Mee et al., 2009), ii) vaginal mucus score of 0 (Williams et al., 2005), and iii) not lame (non-infectious causes were excluded). Health status was graded 0 to 3. A grade of 0 indicated that the normal threshold for all indices had been exceeded (cows were in poor health); grade 1 indicated that 1 health index was normal; grade 2 indicated that 2 health indices were normal; grade 3 indicated that all 3 health indices were normal. The more healthy indices cows had at day 45 postpartum the better their "health status" was at that time. Using this grading system, there were 3 possible outcomes that cows could achieve: i) full health (3 healthy indices); ii) 3 or 2 healthy indices rather than 1 or 0 healthy indices, and iii) 3, 2, or 1 healthy indices rather than 0 health index. AREC (UCD) granted ethical approval.

Results: In weeks 3 to 5, the percentage of mucus samples with scores ≥ 2 was 51, 45, and 43%, respectively; with a steady decline up to week 9 pp. Cytobrush samples (n = 56 cows) found subclinical endometritis

in 43% (24/56) of cows that had 2 consecutive, weekly, clear mucus scores. Only 47 of the 56 cows had a scan taken concurrently with the cytobrush. Thirty of these 47 cows had a normal uterine scan and yet subclinical endometritis was confirmed in 40% (12/30) of them. Odds of involution before or during any of weeks 3 to 5 pp was greater that week for a normal uterine scan (odds ratio; OR = 8.26). Probability of involution did not depend on the mucus score being 0 or > 0. Neither a clear mucus sample (score = 0) nor a normal uterine scan resulted in a greater probability of ovulation either before or during any of weeks 3 to 5 pp. Odds of a healthier reproductive tract on day 45 pp increased by 41% if a cow's IGF-I concentrations were 25 ng/mL higher than another cow in week 3 pp.

Conclusions: i) 2 consecutive clear mucus scores or normal scans do not infer absence of subclinical disease (diagnosed by uterine cytobrush); ii) odds of involution either before or during weeks 3 to 5 pp increased with a normal uterine scan that week but not with a clear mucus score; iii) probability of ovulation either before or during weeks 3 to 5 pp was not related to the uterine health markers (scan or mucus score); iv) a significant relationship was found between IGF-I concentrations in week 3 pp and the reproductive tract health status of cows at day 45 pp. This is a novel finding.

P03-003-212

Pre-calving and early lactation factors that predict fertility and milk proteins in the transition dairy cow

Rachael M. Rodney^{1,2,*}Jenianne K. Hall³Charlotte T. Westwood⁴Pietro Celi⁵Ian J. Lean^{1,2}

¹Scibus, Camden, Australia, ²Faculty of Veterinary Science, University of Sydney, Camden, Australia, ³Halltech Services, Orange, Australia, ⁴Kimihia Research Centre, PG Wrightson Seeds Limited, Lincoln, New Zealand, ⁵Animal Nutrition and Health, DSM Nutritional Products, Columbia, United States

Objectives: This study evaluated the effects of dietary protein degradability (ratio of rumen-undegradable protein (RUP) to rumen-degradable protein (RDP)) and genetic merit (GM) (for milk fat + protein yield) on fertility and production in dairy cows. This study aimed to identify pre-calving and early lactation variables that predict fertility, milk yield, and milk protein yield and composition and explored the hypothesis that low milk protein content is associated with lower fertility.

Materials and Methods: Multiparous Holstein cows (n = 82) of high or low GM were allocated to one of two diets in a 2X2 factorial design. Diets differed in the ratio RUP to RDP (37% vs. 15% RUP) and were fed from 21 d pre-calving to 150 d of lactation. Blood concentrations of beta-hydroxybutyrate, cholesterol, glucose, urea, alpha amino nitrogen (AAN), and NEFA were measured from three weeks before calving. Weekly metabolizable protein (MP) balance was estimated for each cow using CPM dairy (version 3.08; Cornell-Penn-Miner) and metabolizable energy (ME) balance was calculated based on formula described by AFRC (1993). Average blood metabolite concentrations, ME and MP balances, BW and BCS for the 3 weeks before calving, and average milk production variables (milk yield, milk protein and casein yield and percentage) for the first 3 weeks of lactation, were evaluated as indicator variables in statistical models. Casein variant (alpha, beta, gamma, and kappa casein) yields and percentages were determined at weeks 2, 6, and 10 of lactation. The proportion of first services that resulted in pregnancy was explored using logistic regression. Survival analysis was

used to explore the effect of indicator variables on the risk of pregnancy up to 150 d postpartum, with cows separated into quartiles based on their milk protein percentage. Canonical linear discriminant analysis was used to identify traits that differed between groups. Mixed models were used to explore the significance of pre-calving indicator variables on milk yield, and milk protein, casein, and casein variant yield and composition.

Results: A diet high in RUP increased proportion of first services that resulted in pregnancy from 41 to 58%. Increased pre-calving MP balance decreased the proportion of first services that resulted in pregnancy when evaluated in a model containing CN yield, diet, and GM, indicating that the positive effects of a diet high in RUP on fertility may be moderated by retained MP balance in cows with a very positive MP balance before calving. Prepartum MP balance was important for production and reproduction outcomes; while surprisingly, ME balance was not. Cows that produced the lowest quartile of milk protein percentage were 28% less likely to become pregnant during the first 150 d of lactation. Factors associated with lower protein percentage were greater milk production (3.87 L/cow/d more), increased prepartum plasma glucose and calcium, MP balance (497 vs. 414 g/d), and lower blood urea. Increased RUP increased milk yield, and milk protein and CN yields; while, increased GM increased milk yield and tended to increase milk and milk protein yields. Increased GM increased gamma CN yield. Largely consistent associations were found for the effects of indicator variables on CN variant yields and concentrations, with higher BW and AAN resulting in higher yield, but lower concentrations. An increase in cholesterol was associated with decreased CN variant concentrations; while, disease negatively affected CN variant yield.

Conclusions: This study demonstrates the importance of protein metabolism to reproductive performance and supports the hypothesis that low milk protein can be an indicator of poor reproductive performance in the dairy cow.

Resumption of ovarian cyclicity and energy balance in Holstein cows in France based on in-line milk measurements

Claire Saby-Chaban¹René Fournier²Faouzi Lyazrhi¹Edouard Alix³Sylvie Chastant-Maillard⁴Jantijn Swinkels^{5,*}

¹INRA/ENVT IHAP, National Veterinary School, Toulouse, ²MSD Animal Health, Beaucouzé, France, ³DeLaval International, Tumba, Sweden, ⁴INRA/ENVT IHAP, Toulouse, France, ⁵MSD Animal Health, Boxmeer, Netherlands

Objectives: High reproductive performance in dairy herds is a prerequisite for farm profitability. Resumption of post-partum ovarian cyclicity is one of the main limiting factors of reproduction in Holstein cows since fertility is negatively affected by the delay from calving to first ovulation. Most available studies are based on experimental herds, performed in specific conditions. The purposes of this study were to describe the postpartum cyclicity resumption in Holstein cows under current farming conditions in France. We focus on cyclicity resumption, cow energy balance and their effect on reproduction.

Materials and Methods: Data were collected in France during spring 2015 in 21 farms equipped with DeLaval milking robots with a Herd NavigatorND system with DelproND software (DeLaval International, Tumba, Sweden). A total of 1247 cows during the first 90 days of lactation were included. The proportion of primiparous females was

38.3% (478/1247). Progesterone and β -hydroxybutyrate (BHB) were assayed on milk in-line. Progesterone was assayed on average every 2.7 days from 20 to 90 days postpartum (dpp). The delay between calving to the onset of luteal activity (C-LA) was defined as the number of days from calving to the first day with milk progesterone concentration higher than 5 ng/mL. BHB assays, performed every 3 or 4 days during the first 21 dpp, were used to determine the ketosis status. If at least one milk BHB value was greater than 0.15 mmol/L during the first 21 dpp, the cow was declared affected by ketosis. Milk production data were available for each milking. Artificial insemination and pregnancy status were recorded.

Results: Nearly half the cows (45.3%; 565/1247) had resumed cyclicity before 30 dpp and 86.2% (1075/1247) before 60 dpp with significant differences between farms ($p < 0.001$). The proportion (48.9%, 420/859) of young cows (parity 1 or 2) that started cycling before 30 dpp was higher ($p < 0.001$) compared to the proportion of older cows (parity ≥ 3 ; 37.3%, 145/388). Cows that resumed cyclicity before 30 dpp had a lower cumulative milk production over the first 60 dpp than cows resuming cyclicity after 30 dpp (mean \pm sd; 2097 \pm 495 kg vs 2156 \pm 522 kg; $p = 0.05$). In contrast, cumulative milk production over the first 30 dpp had no effect on the resumption of luteal activity ($p = 0.14$). Cows with C-LA lower than 60 dpp (912/1034) were inseminated significantly earlier than those with later C-LA (85.0 \pm 26.5 days vs 105.1 \pm 32.5 days; $p < 0.001$). Similarly, their calving to conception interval was shorter (116 \pm 49.2 days vs 138 \pm 52.6 days; $p < 0.001$).

Overall incidence of ketosis was 19% (237/1247), varying significantly between farms (4.9 to 55.3%, $p < 0.001$). Milk production over the first 60 dpp was significantly higher in cows with ketosis (2087 \pm 495 kg vs 2305 \pm 506 kg). Cows with an early resumption of luteal activity (< 30 dpp) were those with the lowest incidence of ketosis (12.9% vs 24.0% for cows with C-LA > 30 dpp). Cows with ketosis had a longer calving to first insemination interval (86.2 \pm 27.7 days vs 92.7 \pm 28.6 days; $p = 0.005$) and a longer calving to conception interval (116.1 \pm 49.5 days vs 131.8 \pm 51.0 days; $p = 0.006$).

Conclusions: The interval from calving to luteal activity is affected by both ketosis and milk production over the first two months of lactation. In turn, later impact of C-LA on fertility appears of major economic importance. In-line progesterone and BHB assays are very potent tools for dynamic monitoring of reproductive and metabolic status. They especially show the quality of the transition period management: any disturbance evidenced by these indicators needs to be followed by appropriate corrective management solutions. Further analysis of these data will focus on the patterns of postpartum progesterone cyclicity.

P03-003-214

Reproductive outcomes of a blanket herd synchrony program in New Zealand seasonal dairy farms

Greg Chambers¹Mick Clews^{2,*}

¹Zoetis NZ, Cambridge, ²VetOra, Reporoa, New Zealand

Objectives: Successful blanket herd synchrony programs are useful for dairy farmers seeking to reduce dependence on heat detection or simplify their management system. The objective of this study was to assess the herd level reproductive effects of a whole herd synchrony program with fixed time artificial insemination (FTAI) compared to untreated controls in NZ seasonal dairy farms.

Materials and Methods: Lactating dairy cows from 10 seasonally calving pasture-based dairy herds were enrolled. To be eligible, cows must have calved in the current season and more than 34 days before the farm's planned start of mating (PSM). Cows were excluded if birth ID, breed code, date of birth and latest calving date data were unavailable or if the farmer did not intend to mate them in the current season. Heat detection commenced 35 days prior to the planned start of mating (day 0). The enrolled cows were randomly allocated within farm into control and treatment groups. All cows were body condition scored on enrolment. In the control group, cows that had not been observed in heat by 9 days prior to PSM ("non-cycling" cows) were enrolled in the FTAI program and the remaining "cycling" cows were mated to observed heats after the PSM with no mating intervention. All treatment group cows were enrolled in the FTAI program regardless of whether they had been observed in heat prior to PSM or not. The synchrony program consisted of: Day -9: 1.38g progesterone device (CIDR®) inserted & 100µg gonadorelin acetate injected. Day -2: progesterone device removed, 25mg dinoprost injected & 400IU equine chorionic gonadotrophin (eCG) injected. Day 0: 100µg gonadorelin acetate followed by FTAI 10-14 hours later. All synchronised cows from both groups were submitted for FTAI on the farm's first day of mating. Day of conception was determined by aged pregnancy diagnosis with transrectal ultrasound. The primary outcomes compared were 21, 42 and 70 day pregnancy proportions and time to conception.

Results: 4,180 cows were enrolled. 39% were identified as non-cycling at day -9. As the non-cycling cows in both groups were treated with the synchrony program, the analysis describes the synchrony effect in the cycling cows only. Excluding the non-cyclers, blanket herd synchrony significantly increased the odds of conception within 21 days (OR 1.42 (1.21 - 1.67), P< 0.01) and 42 days after PSM (OR 1.40 (1.17 - 1.69), P< 0.01) and tended to increase the odds of conception within 70 days after PSM (OR 1.12 (0.89 - 1.42) P =0.34). Blanket herd synchrony reduced the mean time to conception of the cyclic cows by 7.5 days (P<0.01).

Conclusions: Blanket herd synchrony allowed the farmers to submit all cows on a single day at the start of artificial breeding, thus simplifying heat detection. It resulted in earlier conception within a seasonal mating program, meaning that the cows will calve earlier the following season and therefore may have a longer lactation. This study showed that, in addition to the farm management advantage, whole herd synchrony also significantly improved the reproductive performance of these herds. The shortened time to conception for the treated cows in this study made the program economically viable in NZ.

P03-003-216

Selenium Blood Levels Are Related To Placental Retention, Endometritis And Body Condition Score Loss During Postpartum In Holstein-Friesian Cows

Ramón Miguel Mur Novales¹ Fernando López-Gatius¹ Irina García-Ispuerto¹ Irene López-Helguera¹

¹Agrotecnio Center, Department of Animal Production, University of Lleida., Lleida, Spain

Objectives: To analyze the relationship among Selenium blood levels (Se) since Day 270 of gestation to 4 weeks after parturition and the body condition score (BCS) loss, and reproductive parameters of high producing dairy cows.

Materials and Methods: The study was performed in a commercial farm located in the Northeast of Spain. The farm counts with 850 lactating

dairy cows which are milked 3 times daily and are fed according to the National Research Council recommendations. Forty seven healthy, non-aborting multiparous cows (≥3 lactations) were analyzed. Blood samples were collected from the coccygeal vein at Day 270 of gestation, at parturition and at Days 7, 14, 21 and 28 postpartum (pp). Blood samples were stored at -20°C until analysis. Blood samples were diluted and subjected to an ultrasound bath to break cellular membranes before measure Selenium blood levels through spectrophotometry. The effects of the variables BCS loss (prepartum-Day 14 pp), endometritis and placental retention (PR) on blood Selenium concentrations for all animals were assessed by GLM repeated measures analyses of variance. A binary logistic regression model was built entering PR, endometritis, cyclicity and positive pregnancy diagnosis 28-34 days following first AI as the dependent variable. Independent factors for each dependent variable were: calving season, lactation, inseminating number, bull, days in milk, normalized milk production during the first 305 days in milk of the lactation study period and selenium blood levels at Day 275 of gestation, parturition and Days 7, 14, 21 and 28 pp as independent. All statistics procedures were performed using the SPSS package version 18.0 (SPSS Inc., Chicago, IL, USA) with significance set at P<0.05.

Results: Mean (±SD) blood Selenium concentrations were 128.8±26.3, 140.1±31.2, 128.7±31.3, 116.7±26.6, 111.2±23.7, 109.1±28.1 for Day 275 of gestation, parturition and Days 7, 14, 21 and 28 pp, respectively. Cows losing more than 0.75 points of BCS (n=23) showed higher Se during the whole study period than the remaining animals (n=24) (between subject effect P<0.0001). Endometritis group (n=13) showed higher levels of Se during the study period (between subject effect P<0.0001). Eighteen cows suffered PR. Based on the odds ratios, the likelihood of PR increased in cows with high Se at parturition (by a factor of 1.02) compared to the remaining cows.

Conclusions: Holstein-Friesian multiparous cows showing high levels of selenium in blood during prepartum, parturition and postpartum are losing more BCS, suffer more endometritis during postpartum and more placental retention than the remaining animals.

P03-003-217

Analysis of Systemic Changes in Cows with Subclinical Endometritis

Joseph J. Lim^{1,2*} John J. Callanan¹ Cliona O'Farrelly³ Kieran G. Meade² Aspinas Chapwanya¹

¹Ross University School Veterinary Medicine, Basseterre, Saint Kitts and Nevis, ²Animal & Bioscience Research Department, Teagasc, Grange, ³Comparative Immunology Group, Trinity College Dublin, Dublin, Ireland

Objectives: All cows experience an ascending influx of bacteria through the cervix during and soon after calving. While the majority clear the microbes, a significant proportion (~30%) fails to do so, leading to prolonged endometrial inflammation, uterine disease and subfertility. One of the major causes of decreased fertility postpartum is endometritis and the diagnosis of sub-clinical disease is limited by the lack of sensitive and specific biomarkers. We hypothesise that early systemic immune changes associated with sub-clinical endometritis may provide prognostic indicators of cows which are likely to develop uterine disease.

Materials and Methods: Uterine cytology, mucus scores and peripheral blood evaluations from postpartum cows (n=139) were performed at 7 and 21 days postpartum (DPP). Cytological classification was based on

an 18% polymorphonuclear (PMN) cell cut off at 21 DPP to diagnose subclinical endometritis. Vaginal mucus was evaluated on a scale of 0-3; a score of 0 or 1 indicated the absence of clinical endometritis. Two distinct groups were identified; resolvers (n=10) and non-resolvers (n=10). Both had a vaginal mucus score of either 0 or 1 at both time points and high PMN infiltration 7 DPP (45.5% and 54.1%, resolvers and non-resolvers respectively). However, 21 DPP the resolvers had an average of 8.9% PMN compared to 57.3% PMN for non-resolvers.

Results: There were no significant differences in plasma glucose, non-esterified fatty acid, betahydroxybutyrate and urea levels between resolvers and non-resolvers at any time point. Haematological analysis revealed significant differences in relative neutrophil ($P<0.001$) and lymphocyte ($P<0.001$) numbers systemically at 7 DPP prior to the observed uterine changes at 21 DPP. Pre-calving the non-resolvers had increased relative gene expression of immune receptors, cell surface markers - (TLR2 [$P=0.012$], CD68 [$P=0.047$], CD80 [$P=0.025$] and CD172 [$P=0.009$]); as well as pro-inflammatory cytokines - (TNF [$P=0.06$] and IL6 [$P=0.055$]) compared to cows which had resolved inflammation by 21 DPP. At 7 DPP, CD172 and TNF were also significantly increased in non-resolving cows. Interestingly resolvers only had significantly ($P<0.001$) increased relative gene expression of immune receptor TLR4, 7 DPP.

Conclusions: Results show evidence of systemic immunological changes in cows at 7 DPP, significantly in advance of the usual diagnosis of subclinical endometritis. Furthermore, significant changes in gene expression as early as 62 days pre-calving in cows that develop disease suggests that immune dysregulation may begin before calving. The identification of systemic biomarkers associated with subclinical endometritis will improve reproductive health in cattle by aiding in early detection and prevention of uterine disease.

Redefining the inflammatory gene signature associated with endometritis in bovine endometrial epithelial cells

Amy Brewer^{1,2,*}, Joe J. Lim^{1,3}, Aspinas Chapwanya³, Cliona O'Farrelly², Kieran G. Meade¹

¹Animal & Bioscience Research Department, Teagasc, Grange, Dunsany, Co. Meath, ²Comparative Immunology Group, School of Biochemistry and Immunology, Trinity College Dublin, Dublin 2, Ireland, ³Department of Clinical Sciences, Ross University School of Veterinary Medicine, Basseterre, Saint Kitts and Nevis

Objectives: Bacterial contamination of the uterus is ubiquitous in cattle after calving, and the resulting inflammation can lead to uterine disease if not resolved. Recently our group uncovered a prolonged inflammatory gene signature in endometrial biopsies, associated with the development of endometritis. Endometritic cows displayed consistent inflammation at 7 and 21 days postpartum (DPP), whilst healthy cows showed a decline in inflammatory mediators by 21 DPP. This study aims to validate these results in a larger set of animals and compare the inflammatory signature of the mixed uterine cell population in biopsies with endometrial epithelial cells.

Materials and Methods: Previous work involved collection of biopsy samples from n=9 healthy and n=6 subclinical cows at 7 and 21 days postpartum (DPP). RNA was extracted from the biopsy samples and RNA quality was assessed using an Agilent Bioanalyzer. Following

cDNA synthesis, gene expression analysis was carried out by RT-qPCR. To further investigate gene expression in a single cell population, duplicate cytobrushes were used to collect endometrial epithelial cells from the uterus at 7 and 21 DPP, from a total of 139 cows. Cytological assessment classified animals into groups of high or low inflammation at each time point, based on an 18 % polymorphonuclear (PMN) cell cut-off. Total RNA will be extracted from n=47 cows (n=26 subclinical and n=21 healthy) and relative gene expression analysis performed using RT-qPCR.

Results: Gene expression analysis in uterine biopsy samples supports the presence of a prolonged inflammatory profile associated with endometritis. Greater expression of pro-inflammatory cytokines such as IL1 α , IL1 β and IL18 was observed in subclinical cows compared to healthy cows. Additionally, up-regulation of β -defensin antimicrobial peptides and S100 genes at 21 DPP suggests that infection is on-going in these cows and has not been resolved. Significant differences in histone deacetylase enzymes at 7 and 21 DPP suggest that epigenetic mechanisms may also have a role to play in the postpartum immune response in cattle. Profiling of endometrial epithelial cells will investigate the expression of similar cytokines and antimicrobial peptides and provide additional information on the mechanisms involved in this immune response.

Conclusions: Preliminary findings support the theory of a prolonged inflammatory signature in cows with subclinical endometritis. Investigating this profile in endometrial epithelial samples will allow us to observe the contribution of the epithelial cell to this response, improving our understanding of the innate immune system in postpartum cattle and aiding the development of future intervention strategies for endometritis.

Is crossbreeding a viable option for improving fertility in Australian dairy herds?

Michael Pyman^{1,*}, Joanne E. Coombe¹

¹Faculty of Veterinary and Agricultural Sciences, University of Melbourne, Melbourne, Australia

Objectives: Cow fertility has steadily declined in many countries including Australia in the last thirty years, impacting on both profitability and sustainability. A long-term solution to poor fertility is to select for increased milk production whilst including genetic merit for fertility in breeding plans. However the restoration of fertility to previous levels through the genetic route could take many years and thus alternative approaches need to be promoted and identified through research, development and extension. The use of crossbreeding as a short-term solution for poor fertility in Australian herds has been assessed.

Materials and Methods: Milk production is strongly seasonal in major SE Australian pasture-based regions with peak production being achieved at times of peak growth. The seasonality of the industry means many herds need to calve within a period of four months or less with rebreeding at 12-month intervals to achieve a concentrated calving pattern for the following season. Reproductive performance is therefore essential to maintaining farm sustainability and profitability by concentrating the calving pattern to maximise milk yield and feed utilisation.

In 1996 the InCalf program was created to monitor the reproductive performance of Australian dairy cows. A range of reproductive parameters including 6-week in-calf rate, submission rate and conception

rate achieved in 124 seasonally calving herds were established by the study. A second InCalf project, undertaken in 2009, analysed 74 herds over a ten year period from 2000 to 2009 to determine whether fertility had declined over that period. The study compared figures from the 74 herds to the base parameters derived in the original InCalf project.

Only a small number of Australian studies have looked at the implications, benefits and profitability of crossbreeding under local, pasture-based conditions. The studies were designed to assess whether the reproductive performance of crossbreds, including New Zealand cross Holstein-Friesian cows, in predominantly Holstein-Friesian herds, was superior to that achieved by Holstein-Friesians in terms of submission rate, conception rate, in-calf rate and numbers not pregnant at the end of the breeding period.

Results: The crossbreeding studies showed that crossbred Australian cows had better fertility and longevity than Holstein-Friesian cows with the crossbred herds more profitable than pure-bred Holstein-Friesian herds. This was due to their superior reproductive performance, more compact calving pattern, longer survival in the herd and higher stocking rate. The crossbreds had an 8% higher first service conception rate and six-week in-calf rate and a 5% lower not in-calf rate. Moreover, although Holstein-Friesian cows produced more milk, New Zealand cross Holstein-Friesian cows were shown to have an 8% superior 14-week in-calf rate and a 9% lower not in-calf rate.

The Australian InCalf analysis found all breeds including crossbreds experienced a significant decline in fertility over the period from 2000 to 2009. The typical 6-week in-calf rate decreased by 1% per year with submission and conception rates down by 0.6% and 0.7% per year respectively. However the Jersey Holstein-Friesian first crosses and back crosses had superior fertility to the Holstein-Friesian and Jersey cows in the study herds.

Due to the limited number of crossbreeding studies that have been undertaken in Australia and the increasing interest in crossbreeding programs, Dairy Australia funded a study that commenced in 2015 to assess the use of crossbreeding in Australian herds. The research will determine what breeds are being used, their relative performance and how breeding plans are managed including comparing 2-way with 3-way crosses to provide managers with information on why and how to manage a crossbred herd.

Conclusions: Although selection within breed could address various limitations in dairy genetics over time, combining it with crossbreeding to maintain genetic diversity will improve profitability, longevity and animal welfare. Managers of seasonal calving herds should consider an aggressive approach to the selection of bulls with positive daughter fertility whilst implementing a crossbreeding plan that utilises high genetic merit bulls using two or three different breeds. Establishment of such a crossbreeding program is a serious, long-term commitment requiring selection of specific breeds as well as a type of crossbreeding system to suit the individual.

Influence of Oxytocin Treatment on the Length of Estrus Cycle in lactating Dairy Cows

Stephan Groeger¹, Hartwig Bostedt², Axel Wehrend²

¹Bayer Animal Health GmbH, 51373 Leverkusen, Germany, 51373 Leverkusen, ²Clinic for Obstetrics, Gynaecology and Andrology of Large and Small Animals with Veterinary Ambulance of Justus-Liebig-University Giessen, 35392 Giessen, Germany

Objectives: There is some evidence in elder literature, that application of oxytocin during the early luteal phase influences cycle length in cattle. Armstrong and Hansel (1959) and Donaldson and Takken (1968) reported that treatment with oxytocin during the first week of the estrus cycle led to premature luteolysis between 8 - 12 days after ovulation. The objective of the present study was to verify, if repeated applications of 20 IU oxytocin shorten the estrus cycle.

Materials and Methods: Ten multiparous, lactating Holstein Friesian cows were examined every two days and from day 10 after ovulation on daily via transrectal sonography (8 MHz transrectal probe, LCS scanner 100, Pie Medical®, Maastricht, NL) for follicular growth, time of ovulation and subsequent development of the corpus luteum. From day 10 of the estrus cycle on blood samples were collected to determine serum concentrations of progesterone and estradiol-17β. In group 1 (control; n = 10) for each cow a non-influenced estrus cycle was observed. During the following cycle (group 2; n = 10) each cow received 20 international units (IU) oxytocin intravenously from day 2 until day 6 after ovulation. The parameters cycle length, maximum diameter of the dominant follicle, concentrations of estradiol-17β and progesterone and expression of estrus behaviour were evaluated by means of single-factorial variance analysis.

Results: The mean length of the estrus cycles was 21.9 ± 1.6 days in group 1 and in 21.1 ± 2.1 days in group 2 and thus was not influenced by oxytocin treatment (p = 0.19). The diameter of the preovulatory follicle was not influenced either by the application of oxytocin (15.9 ± 1.6 mm in the untreated group 1 and 16 ± 2.1 mm in group 2, p = 0.98). Also the periovulatory concentrations of progesterone and estradiol-17β and the expression of estrus signs showed no significant difference between both groups (p > 0.05).

Conclusions: No influence of oxytocin treatment on all documented parameters could be observed. The commonly used dosage of 20 IU Oxytocin for the treatment of udder diseases or difficult milking does not influence observed parameters of the estrus cycle in dairy cows.

Study on a corpus luteum with a cavity in dairy cows

Bartłomiej Jaśkowski¹, Karolina Górna², Piotr Boniecki², Marek Gehrke¹

¹Institute of Veterinary Sciences, Faculty of Veterinary Medicine and Life Sciences, ²Faculty of Agronomy and Bioengineering, University of Life Sciences, Poznań, Poland

Objectives: The role of a corpus luteum with a cavity (CLcav) in cows has still been discussed (Kastelic 1990, Kot, 1999). The question on its potential influence on fertility in cows is far open (Perez-Marin, 2009, Hatvani, 2013). The aim of our study was to show the relations between some factors and frequency of the corpus luteum with the cavity (CLcav).

Materials and Methods: Four hundred fifty nine corpora lutea at different stages of the cycle during pregnancy and in non-pregnant cows were ultrasonographically evaluated. A portable ultrasound instrument (Draminski iScan) with a linear probe (7.5 MHz) was used. Ultrasonograms of the corpus luteum (CL) were collected during the routine ultrasound examination and with respect for the veterinary ethics. All CL were measured (diameter, size, volume). The corpus luteum with the cavity was defined as an echodense structure with a non-echodense cavity ≤ 20 mm in diameter (Hatvani, 2013).

Results: Generally, 239 cows and 190 heifers were examined. Ultrasonograms of 459 corpora lutea (CL) were analysed. The mean diameters, sizes and volumes of CL were: 23.23 mm (11 – 43 mm), 465.81 mm² (89– 1412 mm²) and 7999.83 mm³ (694 – 47565 mm³). On average, the CL on the right ovary were smaller in size and volume than CL on the left ovary, however the average diameter of CL on the right ovary was bigger than on the left ovary (23,19 v. 23,18 mm, 458.66 v. 472,24 mm² and 7844,71 v. 8149,16 mm³). The cavity in the corpus luteum was stated in 27.1% more often on the right than on the left ovary (27,1 v. 27%). The average diameter of CLcav was bigger than CL compact (24,45 v. 22,77 mm). The average CLcav had also more luteal tissue than CL compact (7979,59 v. 7634,65 mm³). The corpus luteum with the cavity was more frequent in heifers than cows (35,8 and 20,7%). The average cavity was the biggest in days 6-8 after oestrus, smaller in days 9-14 and the smallest in days 15-19 after oestrus (6-8d:10,09 mm v 9-14d:9,32 mm v.15-19d: 8,5 mm). The percentage of cavities in cows examined for pregnancy was 15,4 for pregnant, whereas for non-pregnant 25,6%. In the presence of two or more CL on one ovary, cavities occurred in 20,5% of double CL and in none of triple CL. The CL with the cavity seems to be the most frequent in autumn, the least likely in winter (spring: 24,7%, summer 26,1%, autumn: 36%, winter: 4,2%). In three CL there were two separated cavities in one CL (0,7%).

Conclusions: Further investigations are necessary to explain differences in frequency of CLcav in respect to the season. Seasonal differences in their frequency are vague. They may have some connection with heat stress and hypoxia.

Effect of postpartum eCG administration in dairy cows calved during the hot season on subsequent fertility after first timed artificial insemination

Raquel Patron¹Irene Lopez-Helguera²Francisco Sebastian³Octavi Fargas⁴Miguel Fernandez³Susana Astiz⁵*

¹TRIALVET SL, Madrid, ²Animal Production, Universitat Lleida, Lleida, ³Granja Sat More, Valencia, ⁴VAPL SL, Barcelona, ⁵Animal Reproduction, INIA, Madrid, Spain

Objectives: Heat stress affects especially fertility of high producing dairy cows. Cows calving during the hot season show a significant delay in the onset of reproductive activity, determining a seasonality of the production, which limits the optimization of profitability. It has been reported that early application of eCG postpartum animals could accelerate the onset of ovarian activity and uterine involution.

The objective of this work was to evaluate the effect of the application of eCG in the early postpartum (at days 11-17 postpartum) on the fertility after first timed AI of heat stressed high producing dairy cows.

Materials and Methods: a total of 400 freshen cows from one single commercial farm (1217 lactating cows) with calvings between 27th June and 3rd of October received randomly 500ui of eCG (eCG-Group; n=213) or saline solution (Control-Group; n=187) at day 11-17 postcalving. At day 96.34±9.88pp a synchronization protocol based on the Double Ovsynch-protocol was applied and all cows were timed artificially inseminated. Ultrasonography examination was performed at day 0 (eCG administration), every 7 days during 3 weeks, and during synchronization and 7 days after AI, in order to assess ovarian activity assessed by presence of a corpus luteum (CL) and or dominant follicle (DF). At day 30 postpartum subclinical endometritis was assessed through cytobrush

uterine cytology (cut-off for Polimorphonuclear Neutrophils MN ≥20%). Pregnancy diagnosis was performed at day 30 and 60 after AI.

Results: Average lactations/cow (2.33 ±1.34), DIM at first AI (96.33±9.88), average milk yield at AI (41.38±7.74L), inseminator distribution (2 inseminators) and used bulls (6 different bulls were used) did not differ between treatments (P>0.05).

The ovarian activity increased with time (with 4.2, 30.2 and 48.4% of animals with CL at weeks 1, 2 and 3 post-eCG, respectively, with a total of 55.1% showing a CL at the beginning of the synchronization protocol. At the time of prostaglandin administration just 31.4% showed a CL. No differences were observed between experimental groups.

At day 30 postpartum 7.7% showed subclinical endometritis (without statistical differences), although the percentage of animals with a hypercogenic intraluminal content (probably purulent content) showed a tendency to be lower in the eCG-Group (21.4 vs. 16.8%; P=0.15). The prevalence of clinical endometritis showed a tendency to be lower in the eCG-Group at 2 weeks after eCG administration (26.2 vs. 19.2%; P=0,059).

Fertility at first AI was 34.9 and 30.4% at 30 y 60d, respectively with no significant difference between experimental groups (day 30 postAI 34.9 vs. 32% and Day60 postAI 30.4 vs. y 28.3%, for eCG-Group and Control. respectively; P>0.2).

Conclusions: Early postpartum application of eCG in heat stressed dairy cows could have benefited slightly endometrial status of the animals, but this did not induce any beneficial effect on the ability to become pregnant at day 30, nor at day 60 after first timed AI. Hence, other strategies should be used in order to mitigate the effect of heat stress during postpartum on fertility of high producing dairy cows.

Predicting the onset of stage two of calving in Holstein-Friesian heifers

Katrin Lange¹*Carola Fischer-Tenhagen¹Wolfgang Heuwieser¹

¹Clinic for Animal Reproduction, Freie Universität Berlin, Berlin, Germany

Objectives: Especially heifers suffer from a high prevalence of dystocia. Dystocia is associated with major pain in the dam and an increased risk of stillbirth in calves. One requirement to prevent and manage dystocia in heifers is to recognize the onset of stage 2 of calving. Therefore the objective of our study was to predict the onset of stage 2. We set out to test the predictive value of six signs of imminent parturition (SIP) and the alteration of the broad pelvic ligaments and filling of the teats.

Materials and Methods: Prior to the experiments a systematic literature search was conducted in which six signs of imminent parturition were identified to be plausible parameters to indicate the onset of stage 2 (i.e., tail raising, scurrying, turning the head towards the abdomen, clear vaginal discharge, bloody vaginal discharge and lying lateral with abdominal contractions). The experiments took place on a commercial dairy farm in Germany milking 2,250 cows. In the first experiment the inter-observer reliability of SIP was tested. A total of 22 Holstein-Friesian heifers around calving were included. Two investigators observed each heifer for 15 seconds once per hour walking behind the cows in the pen. In the second experiment SIP were observed every hour 24 hours from 267 d before calving to parturition. 37 Holstein-Friesian

heifers were included. Additionally to SIP, relaxation of the broad pelvic ligaments (PL) and filling of the rear teats (TF) were examined twice a day and evaluated on a 4-point scale. We calculated a receiver operating characteristic (ROC) analysis for a combination of SIP. One score point was given for the occurrence of each SIP meaning it ranged from 0 to 4. Besides a receiver operating characteristic analysis was conducted for the combination of score points for PL and TF.

Results: Cohen's kappa results for the inter-observer reliability were moderate until almost perfect, ranging between 0.507 and 0.912. The cut-off value for occurrence of SIP was >1 with 83.8 sensitivity and 99.2 specificity. A proportion of 99.2 % of heifers having a score under the cut-off value was correctly diagnosed as not calving. Prediction of calving was possible in 36.5 % of calving events. The results of the area under the curve (AUC) for the combination of PL double weighted and TF was about 0.8, implying that in 80% of the examinations a calving heifer will have a higher PL and TF score than a non-calving one. As the results of SIP and PL TF of the negative predictive value were considerably higher than the positive predictive value, we contemplated predicting no calving. The accuracy of excluding calving for the next 12 hours was 96.8% for 29 heifers examined from day 269 days carried calf until parturition corresponding with a cut off value >5 and a 68.97 sensitivity and 87.91 specificity. A binary logistic regression analysis was conducted to determine the effect of group (i.e., late pregnancy vs. 24 h before onset of stage 2) on the occurrence of SIP. Tail raising, clear vaginal discharge and bloody vaginal discharge were more likely to occur 24h before calving than in late pregnancy ($P \leq 0.001$). While there was a difference in detecting imminent parturition between hourly observation and observation every 3h, 4h, 5h, and 6h, respectively ($P \leq 0.05$), there was no difference between hourly observations and observation every two hours ($P = 0.139$).

Conclusions: Prediction of calving using SIP or the evaluation of PL and TF is challenging. Nevertheless, it is useful to exclude the possibility of calving. Knowing which cow will not calve during next 12 h facilitates monitoring of cows around parturition. The appearance of SIP was very individual regarding the different SIP and the time of occurrence. We could not find a difference between hourly observation and observation every second hour. Hence, we suggest to observe pregnant heifers every 2 hours for tail raising, clear and bloody vaginal discharge and lying lateral with abdominal contractions.

The role of disease in dairy herd reproductive performance

Chris Hudson¹, Jessica Reynolds¹, Amy Smith¹, Jon Huxley¹, Martin Green¹

¹Schpol of Veterinary Medicine and Science, University of Nottingham, Loughborough, Leicestershire LE12 5RD, United Kingdom

Objectives: This abstract summarises the approach and findings of a number of studies which collectively aimed to explore associations between clinical disease events and reproductive performance, both at the level of the individual cow and the herd. The overall objective was to evaluate the potential improvement in a herd's reproductive performance which might be expected as a result of implementing measures to reduce the levels of the major endemic diseases (e.g. mastitis and lameness).

Materials and Methods: Routinely collected herd management data (including cow identity data, insemination and pregnancy diagnosis events and clinical disease records) was collected from a total of 468

dairy herds in England and Wales. Multilevel discrete time survival models were used to explore associations between disease events and reproductive outcomes at lactation level. This statistical approach allowed control for potential measured (e.g. milk yield) and unmeasured (e.g. differences in heat detection standard between herd) confounding variables. A stochastic simulation model was then developed and used to explore the potential for a herd's level of disease to influence its overall reproductive performance. Additionally, the same dataset was used to explore associations between lactation-level reproductive performance and periparturient disease events (e.g. uterine bacterial disease, hypocalcaemia and cystic ovarian disease), using multilevel logistic regression models. A similar dataset was used to explore associations between antibody status for Johne's disease and lactation level reproductive outcome, again using multilevel logistic regression.

Results: Discrete time survival models revealed some statistically significant and relatively large associations between mastitis/lameness events and reproductive outcomes. For example, the odds of a cow becoming pregnant in a given period of time were reduced by 42% in the seven days following a clinical mastitis event. Similarly, odds of pregnancy per unit time were reduced by 24% in the fortnight before or after a clinical lameness case. However, simulation models revealed that, despite these effects, there would be very few situations in which a herd's overall reproductive performance would be altered by a clinically meaningful amount in response to changes in incidence rate of either mastitis or lameness (or in subclinical mastitis as measured by individual cow somatic cell count).

Preliminary results suggest that the odds of a cow becoming pregnant before 100 days in milk (DIM) were reduced where the lactation included a record of a case of retained foetal membranes, uterine bacterial infection or cystic ovarian disease (with reductions in odds of pregnancy by 100 DIM of 31%, 48% and 67% respectively). Odds of pregnancy before 100 DIM were reduced by 79% in cows with a positive Johne's antibody status compared to negative cows. A much smaller association between Johne's status and the odds of insemination at less than 80 DIM suggested that the association with overall reproductive outcome was not explained simply by farmers electing not to inseminate positive cows. Further work is required to interpret these results in the same context as those for mastitis and lameness.

Conclusions: Whilst there are statistically significant associations between reproductive outcomes and clinical records of both lameness and mastitis, improving control of these diseases at herd level is highly unlikely to make a measurable or clinically significant difference to the herd's level of reproductive performance. Preliminary work on the associations between reproductive outcomes and both periparturient disease and Johne's disease status suggest that both have the potential to impact fertility at lactation level to a large degree. Further work would be required to evaluate the potential significance of this at herd level.

Comments: Note: elements of the work summarised in this abstract has previously been published; novel provisional results from further work are also included.

P03-003-225

Accuracy and intensity of estrus detection with activity monitoring systems for lactating dairy cows

Stephen Leblanc¹, Craig Leroy¹

¹Population Medicine, University of Guelph, Guelph, Canada

Objectives: Activity monitors are becoming a widely used tool for estrus detection in dairy cows. The objective of this study is to assess the intensity and accuracy of estrus detection with automated activity monitoring systems.

Materials and Methods: Three commercial dairy farms with an activity monitoring system (Heatime, SCR Inc, or Afi PedoPlus, Afikim) that was used for essentially all inseminations between 50 and 80 days in milk (DIM) were enrolled in this observational study. Herds were visited once weekly. Blood samples were collected at weeks 5, 7, and 9 postpartum and from a subset of cows on the day of insemination, to measure serum progesterone concentration. Cows were examined at week 5 for purulent vaginal discharge (PVD). Lameness and body condition were scored at week 7. Cows were classified as anovular if all 3 blood samples from weeks 5, 7, and 9 had progesterone < 1 ng/ml.

Results: Overall, 6.7% of cows were anovular (range of 3.6% to 8.2% among farms). Of these cows, 39% had a lameness score of 3 or above (1 to 5 scale) and 29% had PVD. Among cows that reached 80 DIM (n=419), 14% had not been inseminated by 80 DIM; of these, 12% were anovular, 23% were lame, 21% had PVD and 4% had a BCS of <2.5%. Among 352 blood samples taken on the day of insemination (all services; 212 signaled by the activity system and 140 by Ovsynch), 8% and 3%, respectively, had progesterone > 1 ng/ml i.e., the cows were not in estrus.

Conclusions: In this sample, the accuracy of detection of estrus by automatic activity monitoring systems under commercial conditions was high. However, a subset of cows would likely require intervention for timely first insemination and only a fraction of these were truly not cyclic.

Effect of two different bovine somatotropins on reproductive outcomes of dairy cows in Brazil

Henderson Ayres¹ Marcilio Nichi² Sandro L. Viechnieski³ Pietro S. Baruselli² Rodrigo Almeida⁴

¹MSD Animal Health, ²Department of Animal Reproduction of USP, São Paulo, ³Star-Milk Farm, Céu Azul, ⁴Universidade Federal do Paraná, Curitiba, Brazil

Objectives: Bovine somatotropin (bST) is recognized as a stimulus for increased milk production. The objective of this trial was to assess the reproductive outcomes of a high-producing dairy cattle herd in response to two commercial sources of bovine somatotropin (bST) administered every 14 days totalizing 16 applications. Our hypothesis was that both bST have the same effect on reproductive outcomes.

Materials and Methods: Eighty Holstein cows from a commercial farm located in the south region of Brazil, averaging 1.76 ± 1.16 lactations, 77.1 ± 21.9 days in milk (DIM) and 37.5 ± 6.5 kg/d of milk were randomly assigned to one of 2 treatment groups using milk production during the 7-day pretreatment period as the blocking criterion. Treatments consisted of 16 consecutive subcutaneous injections of 500 mg of bST (Boostin, MSD Saúde Animal, Brazil) or 500 mg of bST (Lactotropin, Elanco Saúde Animal, Brazil), both administered at a 14-day interval. All cows were milked 3 times a day and received the same total mixed ration fed 5 times daily, consisting of corn silage, ryegrass silage, corn grain ground, soybean meal, whole cottonseed, soybean hulls, urea, minerals, and vitamins. Cows were housed in free stalls. Before the beginning of the trial, 7.5% (6/80) of cows were pregnant (2.5% vs 12.5%, respectively for Boostin and Lactotropin). Data were analyzed with the SAS procedure

mixed with a model containing the continuous effect of the covariate and the fixed effects of block, treatment, day, number of administrations and the interaction between treatment and day and treatment and number of applications. Data were analyzed using the GLIMMIX procedure of SAS software version 9.3.

Results: The data are presented as percentage or mean ± standard error after correction using the final models. Pregnancy rate (%) at the end of the trial was not significantly different (50.0% vs. 55.0%; P=0.32) between both somatotropins. Also, the number of services to pregnancy (3.45 ± 0.54 vs. 3.49 ± 0.40; P=0.93), the interval between calving to pregnancy (129.7 ± 22.9 vs. 130.4 ± 17.1; P=0.97) and the projected intercalving interval (13.5 vs 13.5 mo, P=0.97) were not different between Boostin and Lactotropin, respectively.

Conclusions: These data indicate that there is no statistical significant difference in the effect of the two different somatotropins on reproductive performance (pregnancy rate, number of services to pregnancy, interval calving to pregnancy, and projected intercalving interval) of high-producing dairy cows.

Impact of heat stress on AI and natural service breeding programs in the temperate climate

Laura Schüller¹ Wolfgang Heuwieser¹

¹Clinic of Animal Reproduction, Freie Universität Berlin, Berlin, Germany

Objectives: Reduced reproductive performance of dairy cows in combination with reduced libido and semen quality of bulls during periods of heat stress can cause important economic losses to the dairy industry. Therefore, the breeding type used in periods of heat stress should be considered to maximize reproductive performance.

The objective of the study was to determine the influence of short and long term exposure to heat stress on the CR of lactating dairy cows in different natural service and artificial insemination (AI) breeding programs. Furthermore the relationship between breeding type and parity was determined.

Materials and Methods: The retrospective study was conducted on a commercial dairy farm in Sachsen-Anhalt, Germany from May 2010 to October 2012. The herd consisted of 1,150 Holstein dairy cows with an average milk production of 10,345 kg. The barn was positioned in a NE-SW orientation with open ventilation and a mechanical fan-system. The voluntary waiting period was set at 55 d postpartum. Between 35 and 49 d cows received an initial injection of 25 mg PGF_{2α} (Dinoprost, Dinolytic, Zoetis Deutschland GmbH, Berlin, Germany) and a second injection of 25 mg PGF_{2α} 2 weeks later to regress the corpora lutea. Cows that showed estrus after the second injection of PGF_{2α} were artificially inseminated or received natural service by a bull. Pedometers (Milklime, Gariga di Podenzano, Italy) and visual observation were used to detect estrus. Inseminations were performed within 12 h after detection of estrus with frozen-thawed or fresh semen. Pregnancy diagnoses were performed 35 to 42 d after the day of breeding with transrectal ultrasonography by the herd veterinarian.

Ambient temperature and relative humidity within the barn were recorded using a Tinytag Plus II logger (Gemini loggers Ltd, Chichester, UK) and used to calculate the temperature-humidity-index (THI) according to the equation reported by the NRC (1971):

$THI = (1.8 \times AT + 32) - ((0.55 - 0.0055 \times RH) \times (1.8 \times AT - 26))$.

Short term heat stress was defined as a mean THI ≥ 73 at the day of breeding and long term heat stress was defined as a mean THI ≥ 73 in the period from d 21 to d 1 before day of breeding.

Results: The dataset contained 5,192 breeding records from 1,537 lactating dairy cows on a single dairy farm. The overall conception rate (CR) obtained was 33.0% and average open days were 129.3 d. Inseminations with frozen-thawed and fresh semen were conducted in 80.6% and 5.6% of the cows, respectively and 13.8% of the cows were bred by natural service. Minimum, maximum, and mean temperature-humidity index during the study period were 34.6, 83.7, and $60.4 \pm 8.5\%$, respectively.

Multiparous cows bred by AI with frozen-thawed semen were 22% less likely to get pregnant than primiparous cows. Cows bred by AI with frozen-thawed semen exposed to long term heat stress were 63% less likely to get pregnant than cows not exposed to heat stress. Cows bred by AI with frozen-thawed semen receiving ≥ 4 services were 15% less likely to get pregnant than cows receiving 1 service. There were no significant interactions between heat stress and the variables parity and number of services.

Multiparous cows bred by AI with fresh semen were 67% less likely to get pregnant than primiparous cows. Cows bred by AI with fresh semen exposed to short term heat stress were 80% less likely to get pregnant than cows not exposed to heat stress. There were no significant interactions between heat stress and parity.

In the multivariable logistic regression model investigating cows bred by natural service, the variables heat stress ($P = 0.21$), parity ($P = 0.98$) and number of services ($P = 0.24$) had no significant association to CR.

Conclusions: The present study indicates, that the likelihood to get pregnant is reduced by short and long term heat stress depending on the breeding type. Especially CR of cows inseminated with fresh semen are negatively affected by short term heat stress and cows inseminated with frozen-thawed semen are negatively affected by long term heat stress. The CR of cows bred by natural service were not affected by short and long term heat stress. Therefore climate conditions should be considered in the selection of breeding strategies to optimize AI and resulting CR. During periods of short term heat stress the application of fresh semen needs to be improved.

Effect of insemination after estrous detection on pregnancy per AI and pregnancy loss in a Presynch-Ovsynch protocol: A meta-analysis

Stefan Borchardt¹, Wolfgang Heuwieser¹

¹Clinic for Animal Reproduction, Faculty of Veterinary Medicine, Freie Universität Berlin, Berlin, Germany

Objectives: Presynchronization of cows with 2 injections of prostaglandin administered 14 d apart (Presynch-Ovsynch) is a widely adopted procedure to increase pregnancy per artificial insemination (P/AI) for the first service. Two different strategies can be observed. Either all cows are time-inseminated (onlyTAI) or cows detected in estrus after the second PGF_{2a} injection are inseminated and the remaining cows without signs of estrus will be subject to TAI (EDAI+TAI). The objective of our study was to evaluate the effect of insemination after estrous

detection during a Presynch-Ovsynch protocol for first service on fertility in lactating dairy cows.

Materials and Methods: A systematic review of the literature was performed. Two statistical approaches were conducted using a fixed or a random effects meta-analysis based on the heterogeneity among the experimental groups. Reproductive outcomes of interest were P/AI measured on d 32 (28 to 42) and pregnancy loss between d 32 and 60 (42 to 74) of gestation. In approach 1, 3 randomized controlled studies including 1,689 cows with the primary objective to evaluate the effect of insemination after estrous detection in a Presynch-Ovsynch protocol were used. In approach 2, cows from approach 1 and cohorts from another 17 experimental groups including 8,124 cows submitted to first AI using a Presynch-Ovsynch protocol were used. Information regarding pregnancy loss was available for 5,200 cows.

Results: In approach 1, the incorporation of insemination after estrous detection decreased the odds of pregnancy by 35 % (OR = 0.65; 95% CI = 0.53 – 0.80) on d 32 after AI using a fixed effects model. There was no effect on pregnancy loss on d 60 of gestation (OR = 0.88; 95% CI = 0.55 – 1.43). There was no heterogeneity among the 3 studies regarding P/AI and pregnancy loss.

In approach 2, the overall proportion of P/AI was 30.9% (95% CI = 26.71 – 35.28; n = 2,400) and 41.7% (95% CI = 39.76 – 42.01; n = 7,413) on d 32 after AI for EDAI+TAI and onlyTAI, respectively. The overall proportion of pregnancy loss was 11.7% (95% CI = 6.11 – 18.8; n = 1,811) and 9.6% (95% CI = 6.37 – 13.33; n = 3,389) on d 60 after AI for EDAI+TAI and onlyTAI, respectively. There was substantial heterogeneity among the experimental groups regarding P/AI and pregnancy loss.

Conclusions: Based on a meta-analysis considering 20 manuscripts including 27 herds and 9,813 AI we compared 2 different management strategies for first service using a Presynch-Ovsynch protocol. Cows with 100% TAI after completing a Presynch-Ovsynch protocol had more P/AI compared to cows that were inseminated after estrous detection or received TAI for cows showing no signs of estrus. The results of this meta-analysis are based on a large number of herds with different managerial conditions and seem to be applicable to high producing dairy herds under confinement housing.

P03-003-230

Distribution of inflammation within the endometrium of dairy cows

Oswaldo Bogado Pascottini¹, Miel Hostens¹, Pouya Dini¹, Jan Vandepitte¹, Richard Ducatelle², Geert Opsomer¹

¹Department of reproduction, obstetrics, and herd health, ²Department of pathology, bacteriology, and avian diseases, Ghent University, Merelbeke, Belgium

Objectives: Aims of the present study were twofold: 1) to compare the distribution of polymorphonuclear cells (PMNs) in 8 pre-defined locations of the endometrium, and 2) to compare the PMN counts between the superficial endometrium (epithelium adjacencies) and PMNs present in the stratum compactum.

Materials and Methods: Holstein-Friesian cows (n= 32) from a single dairy farm at 315 \pm 173 days in milk were selected for the present experiment. The day before cows were slaughtered, a complete reproductive examination was performed to discard any type of clinical disease. After slaughtering, reproductive tracts were collected, and the

endometrium was sampled at eight predefined locations. Locations were as follows: (1) tip of the left horn, (2) median part of the left horn, (3) basis of the left horn, (4) left side of the uterine body, (5) right side of the uterine body, (6) basis of the right horn, (7) median part of the right horn, and (8) tip of the right horn. At each location, endometrial biopsies and cytology samples were taken with an 8.0 mm biopsy punch and a cytobrush, respectively. Histopathology samples were stained with Naphtol-AS-D-chloracetate-esterase, while cytology samples were stained with Diff-Quick®. Histopathology slides were evaluated by counting and averaging PMNs in 5 high power fields while cytology samples were evaluated by counting and averaging PMNs in 10 high power fields. For the histopathology samples, PMN counts were differentiated as: PMNs in direct contact with the epithelial cells of the endometrium (PMN-EP), and PMNs present deeper in the stratum compactum (PMN-SC). Summation of both countings was referred to as PMN total (PMN-T). A Poisson mixed effect model was used to analyze the distribution of PMNs within the uterus, and the Tukey method to assess the difference between the estimates of the 8 pre-defined locations (PMN-T), and between PMN-EP and PMN-SC.

Results: In total, 512 acceptable sample slides were obtained: 256 biopsies and 256 cytologies; representing the 8 predefined locations of the 32 uteri. Significantly ($P < 0.05$) higher PMN counts were found in the deep stratum compactum (PMN-SC), in comparison to the superficial endometrium (PMN-EP), and the cytology samples. However, no differences were found in the number of PMNs between cytology and PMN-EP ($P > 0.05$). Significant differences ($P < 0.05$) concerning the number of PMNs were found between the different locations, with higher PMN counts in locations 4 and 6.

Conclusions: Closing, the adjacencies of the corpus uteri should be considered as the preferred location to take uterine biopsies or cytobrush samples in cows, since more PMNs were found in these regions. An uneven distribution of PMNs was found between PMN-EP/cytology and PMN-SC, suggesting that when cytology samples are taken, only the superficial layer of the endometrium is sampled and evaluated.

The use of artificial insemination in dairy herds in the Northwestern Rio-grandense mesoregion, Brazil

Heitor J. Cervo¹Júlio Otávio J. Barcellos¹Vanessa Peripolli²Concepta McManus²Carolina M. Lucci^{2*}

¹Animal Science, Federal University of Rio Grande do Sul,, Porto Alegre, ²University of Brasilia, Brasilia, Brazil

Objectives: The objective of this study was to determine the association between the use of artificial insemination and other factors on productive performance of dairy cows in the Northwestern Mesoregion of Southern Brazil.

Materials and Methods: Data were obtained through questionnaires with milk producers of the Northwestern Mesoregion and information on the number of people trained by municipality in the technique of artificial insemination (AI) was obtained from the Federal Institute of Education, Science and Technology of Rio Grande do Sul. The farmers (195) belonging to 216 municipalities that make up this mesoregion were randomly selected for analysis and classified according to production activities, capital investment, technology and use of artificial insemination. The variables were standardized, assuming mean zero and variance one. Analysis of variance was used to evaluate herd size

milk production and the size of the property. The variables used in the analysis were number of dairy cows, dry cows, calves up to 1 year, males, bulls, working animals, total number of animals, amount of milk produced per lactating cow, monthly milk production, price received per liter of milk and area for pasture production. Means were adjusted by least squares method. Qualitative variables (nutrition of dairy cattle, management of animals and pastures, capital investment, and reproductive technologies) were categorized. Multivariate analyzes including cluster, canonical discriminant and correspondence analyses were performed to determine the factors that could influence the sources of variation. The area of the property was set to 1 (up to 40 ha), 2 (between 40 and 100 ha) or 3 (over 100 ha) and the time in the dairy business as 1 (under 5 years), 2 (between 5 and 10 years) or 3 (over 10 years).

Results: Four clusters were formed due to production traits and farm size. The difference in properties of high production and large size area to low production and small size area was that the former had on average 11 times more total animals and lactating cows per year. They also produced monthly 20 times more milk and had assigned 44 times higher area for food production for the dairy herd. Two factors explained 69.76% of the variance between the clusters. Discriminant analysis showed that production best explains the difference among the clusters formed. Correspondence analyzes showed that more artificial insemination use is associated with higher milk production and factors related to production. Use of artificial insemination was linked to higher productivity, the size of the property, the length of time the farmer was in the dairy business and the higher price received per liter of milk sold. However a negative association among the use of AI and grazing native pasture, use of common salt and crop residues, and positive association with the use of conserved forage, concentrates and mineral salt for feeding livestock were observed. Also, the properties belonging to the municipalities that had the highest number of people trained for the use of AI was associated with increased production, the largest investment in area and land, physical, institutional and human resources. The association of the use of AI with embryo transfer, fixed-time artificial insemination, pregnancy diagnosis and sexed semen was positive.

Conclusions: The use of artificial insemination in the Northwestern Rio-grandense Mesoregion was associated not only with increased productivity, but also with the use of other technologies necessary to meet the needs of global production systems and specialized technified milk production.

P03-003-232

Benchmarking reproductive parameters dairy farms worldwide

Yolanda Trillo^{1*}Gumer De La Riera²Pedro Meireles³Iris Kaimio⁴Timo Tamm⁵Samuel Antuñano⁶

¹International Distribution Manager, BCF technology, Bellshill, Scotland, United Kingdom, ²Easi-Scan distributor, La Espina, Spain, ³Easi-Scan distributor, Fradelos, Portugal, ⁴Easi-Scan distributor, Hiltulanlahti, Finland, ⁵Easi-Scan distributor, Tartu, Estonia, ⁶Easi-Scan distributor, Jalisco, Mexico

Objectives: To describe and benchmark reproductive parameters in 10 dairy farms located in Spain, Portugal, Estonia, Finland and Mexico to find opportunities to improve in the reproduction management performance.

Materials and Methods: Several reproductive parameters were collected from 10 dairy farms by veterinarians in different regions of the

world (cows range): Northwest Spain (56 – 83 cows), Portugal (42 – 530 cows), Estonia (157 – 2,152 cows), Finland (33 – 130 cows) and Mexico – La Laguna (450 – 680 cows).

Initially veterinarians were asked to collect 7 parameters: days of calving to first service interval (CFSI), percentage of conception at first service (FSC%), days of calving to conception interval (CCI), percentage of heat detections (HD%), average of calving number (CN), percentage of average conception (C%) and Days in Milk (DIM). However it was not possible in several countries because their different software systems for keeping records did not include some of the proposed ones (Estonia) and, instead, others were provided (Finland): Non return rate - 60 days- (NRR%), Calving Interval days (CI), number of IA per calving (IA/C).

Descriptive results are reported by second quartile (Q_2) or percentile 50th, which represents the median / 50% of the data and, range (data dispersion/variation): Median (minimum - maximum).

Results: Spanish, Portuguese and Astonish farms had a close CFSI: 77 (67 – 122), 74 (55 – 82) and 74 (69 – 85) respectively. However Spanish dairies had a big variation, similar to Mexico but within a low range of days: 66 (56 – 100). While Finland reported: 88 days (80 -105).

Astonish farms got a good FSC%: 47 (34 – 55) and a small variation across farms. Spanish and Mexican farms had similar values: 32 (18 – 50) and 31 (28 – 40) respectively. However, variation across Spanish farms was high, as it was in Portuguese farms: 37 (22 – 51). Finish farms recorded a NRR% of 56 (43 – 76).

Within Spanish farms there was a high variation on the CCI: 146 (112 – 189). However, within Portuguese, Astonish and Mexican farms there was a low variation: 115 (106 – 137), 117 (105 – 136) and 115 (110 – 120) respectively. Finish farms reported a CI of 408 days (385 – 440) and Astonish farms had 393 days (383 – 409).

HD% is a subjective record as it depends on farmer's collection. It varied as follow: Spain 59 (46 – 68), Portugal 50 (36 – 66) and Mexico 50 (55 – 65). While Finland recorded IA per calving: 2,1 (1,5 – 3,2).

CN was from high to low values as follow: Spain 2,7 (1,9 – 3,5), Portugal 2,3 (1,9 – 2,8), Finland 2,2 (1,7 – 3,2) and Mexico 1,2 (1 – 2).

Spain and Portugal had a close C%: 39 (25 – 42) and 38 (29 – 47) respectively. However Mexican farms were far from this performance: 29 (25 – 32).

DIM varied widely among farms: Portugal 172 (159 – 186), Spain 157 (148 – 222) and Mexico 150 (140 – 160).

Conclusions: Spanish and Portuguese farms seems to have similar reproduction management as well as between Finland and Astonish farms. However, Mexican reproductive parameters differ from European countries; in contrast, variation within La Laguna farms was small.

Benchmarking across farms could not be established because of data source (equations) variation as well as some missing values. Moreover, differences on cow breeds reproduction performance and farm management must be considered. Therefore only a unified worldwide software able to correct for several parameters could bring opportunities to improve among countries worldwide.

Comments: *We will include more countries on the poster presentation.

Follicular dynamics in postpartum dairy cows with abnormal resumption of ovarian cyclicity

Wakana Takahashi¹ Miho Kurimura¹ Chikako Yoshida²

¹Graduate School for Science and Technology, Niigata University,

²Field Center for Sustainable Agriculture and Forestry, Niigata University, Niigata, Japan

Objectives: It has recently been reported that more than half of lactating dairy cows show abnormal resumption of ovarian function after calving. There are two typical patterns of abnormal ovarian resumption: the delayed first ovulation (DOV) and the prolonged luteal phase (PLP). The follicular dynamics in these abnormal postpartum ovarian cycles are not yet known. This study aimed to describe the follicular dynamics in postpartum dairy cows with abnormal ovarian cyclicity.

Materials and Methods: Fourteen cows that calved from Jul 2013 to Sep 2014 were used. Examination period for each animal was from 60 days before calving to the day of first artificial insemination after calving. Body weight, body condition scoring (BCS) and blood components (glucose, nonesterified fatty acid, 3-hydroxybutyric acid and γ -glutamyl transpeptidase) were analyzed to reveal nutritional state. Ovarian resumption and uterus involution after parturition were examined 3 times/week until insemination. Number and diameter of follicles and corpus luteum (CL) were diagnosed with ultrasonic echography. Follicles with diameter ≥ 8 mm were defined as dominant follicles (DF). Plasma progesterone (P4) concentration was measured by ELISA to monitor CL function for the same period. Pattern of ovarian resumption was classified as normal, DOV (first ovulation delayed >35 days after calving) or PLP (luteal phase prolonged >20 days); PLP was classified according whether prolonged luteal phase occurred at the first (PLPI) or second (PLPII) estrous cycle. The maximum diameter, frequency of ovarian domination, interval and duration of each follicular wave and number of ovulations were recorded to describe follicle development. Estrous signs were detected from genital changes and estrous mucus discharge, and also heat detection aids.

Results: After calving, 50% of the 14 cows had normal ovarian resumption, 28.6% of cows had DOV, 14.3% of them had PLP and 7.1% were others. All had normal uterine resumption. BCS change in the DOV and normal groups were similar. Ranges of BCS change and body weight loss after calving in PLP animals were slightly narrower than other groups. Blood glucose levels were higher in the DOV group than the normal group; other blood parameters did not significantly differ within groups. In the normal group (n=7), follicular waves occurred 1.5 ± 0.2 and 2.0 ± 0.0 times (in average \pm SD) with duration 6.3 ± 1.9 and 8.2 ± 1.2 days at the first and second estrous cycles, respectively. Concentration of blood P4 was 2.1 ± 0.2 and 2.8 ± 0.3 ng/ml at the first and second luteal phase. In DOV (n=4), 2.8 ± 0.5 follicular waves occurred with first ovulation 36.0 ± 0.0 days after calving. Duration of the first and second follicular waves after calving was 17.0 ± 3.3 and 10.0 ± 1.0 days. Follicular waves occurred 1.8 ± 0.3 and 2.0 ± 0.0 times with duration 7.3 ± 2.1 and 5.5 ± 1.2 days at the following cycles. Concentration of blood P4 was 2.1 ± 0.4 and 2.6 ± 0.4 ng/ml at the first and second luteal phase. In PLPI (n=1), follicular waves occurred 3 times with duration 15, 10 and 8 days in the prolonged luteal phase. The average blood P4 level was 3.0 ng/ml and diameter of CL was 27.3 mm in the same period. In PLPII (n=1), follicular waves occurred 4 times with duration 14, 10, 13 and 2 days in the prolonged luteal phase, with double ovulation. Average concentration of P4 in that phase was 3.1 ng/ml and diameter of CL was 20.2 and 22.4 mm.

Conclusions: Abnormal ovarian resumption in cows postpartum was similar with past reports. Follicular dynamics in DOV of relatively

longer duration of follicular waves was seen before first ovulation, but it normalized after recovery of estrous cycles. In PLPI and PLPII, relatively prolonged duration of follicular waves repeated within the prolonged luteal phases.

100µg gonadorelin acetate combined with cloprostenol sodium in a fixed-time artificial insemination program for estrous synchronization in dairy cows

Lina S. de Montigny¹Terry Katz¹Paul M. Baldwin²Jantijn Swinkels^{1*}

¹Merck Animal Health, Madison, United States, ²MSD Animal Health Innovation S.A.S, Beaucouzé, France

Objectives: In 2013, the use of 100µg of gonadorelin base (as gonadorelin acetate, GonaBREED[®]) was approved in the USA for sequential use with 500 µg of cloprostenol for use in single fixed-time artificial insemination (FTAI) programs (Ovsynch) in dairy cattle. The objective of this study was to generate clinical data to obtain US registration of a lower dose of gonadorelin (100µg of gonadorelin acetate, containing 86 µg of gonadorelin base, FERTAGYL[®]) for use in sequence with 500 µg of cloprostenol in the afore mentioned single fixed-time artificial insemination (FTAI) programs.

Materials and Methods: A clinical field study was conducted across seven dairy farms in six US states. Healthy non-pregnant dairy cows between 51-119 days in milk were randomized within farms to a gonadorelin-treated group (2mL Fertagyl[®], containing 86µg gonadorelin, present as the acetate salt) or a saline-treated control group. Enrolled cows were treated on Day 0 with 2mL Fertagyl[®] (N = 377) or 2mL saline (N = 381); Day 7 with 2mL Estrumate[®] (500µg cloprostenol); and on Day 9 with 2mL Fertagyl[®] or 2mL saline (as on Day 0). Cows were then bred by FTAI on Day 10, 16±8 hours after the Day 9 injections. Pregnancy checks were performed at least 30 days later. Most cows were first or second parity (gonadorelin group 62.1%; control 64.6%). Across the study, heat stress conditions were recorded on two farms: for 10 days on one; 2 on the other. Of 758 cows enrolled, 744 were included in the efficacy analysis.

Results: Overall, the pregnancy rate (PR) was significantly higher in the gonadorelin group compared to the control group (33.4% (125/374) vs. 17.8% (66/370); p=0.0051). There were no treatment related adverse events. Heat stress did not appear to affect the ability of the gonadorelin-cloprostenol synchronization treatment to increase PR, compared to the control group. The 33.4% PR obtained herein with a 86µg dose of gonadorelin (present as the acetate salt) compares favorably to the 33.4% PR reported for the 100µg dose of gonadorelin (present as the acetate salt) that was recently registered in the USA, and also with the 32.2% PR that has been reported in an Ovsynch FTAI program using a 200 µg dose of gonadorelin present as the hydrochloride salt.

Conclusions: The results of this study demonstrate that a 100µg dose of gonadorelin acetate (containing 86µg of gonadorelin base) used in sequence with 500µg cloprostenol is effective for estrus synchronization of dairy cattle in FTAI programs. The effectiveness of the lower dose of gonadorelin (86µg) used in this study compares favorably with that reported for higher doses of gonadorelin, whether present as the acetate or the hydrochloride salt.

P03-003-235

Using inter-service intervals to monitor oestrus detection: does one size fit all?

John Remnant^{1*}Martin Green¹Jon Huxley¹Chris Hudson¹

¹School of Veterinary Medicine and Science, University of Nottingham, Loughborough, United Kingdom

Objectives: Effective oestrus detection is essential in the modern dairy herd using artificial insemination. One frequently used method for evaluating oestrus detection is to assess the distribution of inter-service intervals.

The aims of this study were to:

- Assess inter-service interval performance in a large number of herds to provide data for benchmarking and target setting
- Evaluate what constitutes a “normal” inter-service interval for a modern dairy cow
- Identify whether the “normal” interval within a herd affects our interpretation of inter-service interval profiles

Materials and Methods: Herd management records were collected from 468 UK dairy farms. After checks were carried out to ensure appropriate data quality data from 74,923 cows in 167 dairy herd remained. Intervals between subsequent inseminations (serves) in the same cow in the same lactation were categorised in relation to the expected normal oestrus interval of 18-24 days. The standard categories include: short irregular (2-17 days), short regular (18-24 days), long irregular (25-35 days), long regular (36-48 days) and extended (49 days plus). Inter-service intervals profiles were calculated for every calendar year of every herd and ranked by oestrus detection efficiency to allow target setting. More detailed analysis of the distribution of inter-service intervals around the expected 21 day peak was conducted using multi-level regression modelling to identify cow factors affecting inter-service interval (Remnant et al, Journal of Dairy Science, 98 p.889). Data on this “normal” inter-service interval was then used to identify whether the interpretation of many herd inter-service interval profiles was affected by variations in the normal inter-service interval of a cow in the herd.

Results: The average performance of the top quartile of herd calendar-years was to have 6%, 40%, 16%, 19% and 19% of inter-service intervals in the short irregular, short regular, long irregular, long regular and extended categories respectively. Analysis of the inter-service intervals around the expected peak at 21 days revealed a modal interval of 22 days with significant associations between inter-service interval and parity, milk yield, service number and days in milk. However most of the variation in inter-service interval was between oestrus cycles within a cow and remained unexplained. This extended “normal” interval appears to affect the interpretation of oestrus detection data in some herds. No clear associations of herd-level factors with the effect on data interpretation were identified.

Conclusions:

- Inter-service interval profile performance of UK dairy herds appears to be considerably lower than traditionally quoted targets. This study suggests more appropriate and achievable targets as described by the top quartile of herd calendar-years described above.
- The normal inter-service interval of dairy cows appears to be longer than the traditional 18-24 days, we believe this to be a reflection of cows having a longer oestrus cycle than commonly accepted.
- This extended “normal” interval does affect interpretation of inter-service interval profiles, but it does not appear possible to identify which herds will be affected.

P03-003-236

Influence of Bio-Active Peptides from Fpp (Fermented Potato Protein) on Reproductive and Production Performance in Dairy Cows

Stefaan Bekaert ¹; Kate Lin ²

¹Marketing, Huvepharma, Antwerpen, Belgium, ²Technical service department, Huvepharma, Taipei City, Taiwan, Province of China

Objectives: In dairy cows, there is evidence to link a NEB associated decline in fertility to reduced concentrations of Insulin like Growth factor I (IGF-I). IGF-1 is a likely candidate to mediate this effect of NEB on reproduction¹. Former research demonstrated that IGF-1 is involved in ovarian physiology and folliculogenesis^{2,3,4,9} and milk production in cattle⁵. Own research demonstrated a positive effect of Lianol[®] Dairy, a complementary feed based on highly digestible fermented potato protein, on IGF-1 levels in cows⁶. This study focuses on the effect of supplementing this new product on reproductive parameters and milk production in dairy cattle.

Materials and Methods:

Experimental animals

The experiment was conducted at Shen Xing dairy farm of Shanghai Bright Holstein Co. Ltd. Forty cows in close-up period were chosen based on parity, body weight (600±30kg), body condition scoring, and were assigned randomly into 2 treatment groups with 20 cows per group.

Experimental treatments

A control group was fed a basal diet; the treatment group was fed the same basal diet with addition of Lianol Dairy (25g/d/cow) from 20 days before calving to 40 days after calving.

The basal diet was formulated based on “Feeding standard of China dairy cattle”(NY/T 34-2004). The trial was conducted with 10 days adaptation and 170 days test period (from 20 days before calving till 150 days after calving or 150 days in milk (DIM). Both groups were fed with a total mixed ration (TMR) three times per day, with free access to water. The experiment duration was from Mar 20th to Nov 30th in 2014.

Measurements

Milk production of each cow was recorded at 7, 40, 60, 90, 120, 150 DIM during the test period. Estrus time and calculated conception rate at 90 d, 120 d and 150 d after calving. Conception was checked with SPB (pregnancy specific protein B) in blood of cows with ELISA. From interval calving-conception, the calving interval was calculated.

Statistical analysis

Data were sorted using Excel 2003 software and analyzed using SPSS16.0 by T test. The data of the conception rate at 120 d, and 150 d after calving were analyzed by chi-square test. Treatment effects were considered significant at P<0.05.

Results: There were no significant difference in average milk yield recorded. But treatment group had numerically higher milk yields than the control group (see table 1.). Especially for 7, 40 and 90 DIM with respectively 2.6 kg (+8%), 2.4 kg (+5.9%) and 2.7 kg (+7.4 %). Over the whole testing period, the daily milk yield was increased by 3.9 % (150 days).

Table 1. Effect of lianol Dairy on milk yield (kg) at different sampling points.

Sample point	Control group (in kg milk)	Liano [®] group (in kg milk)	P-value
7 DIM	32.4 ± 7.0	35.0 ± 8.5	0.301
40 DIM	40.8 ± 5.1	43.2 ± 8.1	0.256
60 DIM	40.6 ± 5.1	41.1 ± 7.0	0.827
90 DIM	36.1 ± 6.4	38.8 ± 6.0	0.253
120 DIM	35.4 ± 5.1	36.2 ± 4.4	0.650
150 DIM	32.4 ± 8.2	33.5 ± 7.1	0.697
Total period	36.1 ± 4.1	37.5 ± 5.6	0.440

There were no significant differences in interval calving-1st service and calving-interval between the two groups (Table 2). The average calving interval of the treatment group was shorter than this of the control group (380 d vs 397 d, p=0.118). The conception rate at 120 days and 150 days DIM was increased in the treatment group (resp. 80.0% vs 53.3%; P=0.121 and 93.3% vs 73.3%; P= 0.142).

Table 2. The effect of Lianol dairy on reproductive parameters: interval calving-1st insemination, calving interval and conception rate at different DIM.

Control group	Lianol group	P-value	
Interval Calving-1 st service (days)	83 ± 20	86 ± 13	0.578
Calving interval (days)	397 ± 35	380 ± 22	0.118
Conception rate (%):			
90 DIM	33.3 %	40.0 %	0.705
120 DIM	53.3 %	80.0 %	0.121
150 DIM	73.3 %	93.3 %	0.142

Conclusions: IGF-1 concentrations can influence follicle development during and after lactation directly by increasing the follicular response to gonadotropins or indirectly by acting on the hypothalamus and thereby influencing pulsatile LH release by the pituitary^{7,8}. Former research has demonstrated a positive effect of Liano[®] Dairy on plasma IGF-1 levels in cows⁶. This trial demonstrated a large effect on milk yield and reproductive performance. Supplementing the new product resulted in an increased milk yield production (+3.8%) over the whole trial period. The calving interval was reduced with 17 days and the conception rate was increased with 20%.

Ultrasound characteristics of ovarian cysts in cows – results of two-year observation

Bartłomiej M. Jaśkowski ¹; Jakub Kulus ¹; Magdalena Woźna ¹; Jędrzej M. Jaśkowski ¹; Marek Gehrke ¹

¹Institute of Veterinary Sciences, Faculty of Veterinary Medicine and Animal Sciences, University of Life Sciences, Poznań, Poland

Objectives: Ovarian cysts are still a significant cause of cows infertility. The ultrasounds examination provides opportunities for a more accurate diagnosis. The aim of the study was the morphological characterization of ovarian cysts in Polish Holstein Friesians.

Materials and Methods: The study included 270 cows and heifers in which, with the use of ultrasounds (iSkand, 7.5 MHz linearprobe), cysts were found. All of the animals came from 6 herds with milk production > 10000 liters. In all those herds regular veterinary examinations were taking place every 3-4 weeks. Ovarian structures with the cavity > 20mm in diameter and a luteinized wall > 3mm in diameter were recognized as lutein cysts, meanwhile structures with the cavity > 20mm and a luteinized wall ≤ 3mm were classified as follicular cysts (Hatvani, 2013).

Results: In general 323 cysts were evaluated. 220 (68%) in this group were follicular cysts, 103 of them (32%) were lutein cysts. The average diameter, surface area and volume were respectively 33mm, 897mm² and 22289 mm³. Cysts were observed mostly on the right ovary (74%), less often on the left (18%), or on both ovaries at the same time (8%). The average lutein cysts were bigger than follicular (34mm to 32,8mm). Symptoms of nymphomania appeared in 23 cows (8%), in 39% of those cows cysts were on both ovaries. There was no relation between size of cysts and appearance of nymphomania. The rest 267 cows were reported due to anestrus. The most common cysts were single-chambered, however there were also two-, three- or multi-chambered cysts (222, 39, 3 and 2 (68.7, 12.1, 0.9 and 0.6%, respectively). In rare cases ovarian cysts were accompanied by the corpus luteum (4%). Of all analyzed cysts in the period to 60 days after calving follicular creations occurred more often than lutein (57 to 43%). In the period from 60 day to 120 and > 120 day the incidence of follicular cysts was higher (resp. 74 and 72%). The percentage of follicular cysts in heifers, primiparous cows and cows after 2, 3 and 4 lactation and > 4 lactation was 6, 27, 36, 12, 10 and 9%, respectively. In 5,5% of cows, cysts persist intact despite of treatment.

Conclusions: Ultrasounds examination provides more valuable data, including the size, structure and types of ovarian cysts. It allows also to specify the connection between frequency of cysts and number of lactations, days after calving and clinical signs. On the base of ultrasounds examination more precise treatment can be introduced.

Monitoring Bovine Viral Diarrhea and Infectious Bovine Rhinotracheitis infections in dairy cattle using precolostral sampling

Paul Baillargeon¹Juan Carlos Arango Sabogal²Vincent Wellemans²Gilles Fecteau²

¹Zoetis, 16740 Trans-Canada Highway, Kirkland, ²Sciences Cliniques, Faculté de médecine vétérinaire, Université de Montréal, Saint-Hyacinthe, Canada

Objectives: The objective of the present study was to evaluate precolostral sampling as a tool to determine Bovine Viral Diarrhea and Infectious Bovine Rhinotracheitis status and infection in Québec dairy herds.

Materials and Methods: A convenience sample of 346 sera from 50 Québec dairy herds was used in the study. Out of them, 259 samples were taken between February 2005 and March 2008 by veterinarians and dairy producers who participated on a voluntary basis. The additional 87 samples originated from a previous study and were collected between August 1999 and October 2000 and were stored at -70 °C. At the moment of the visit, herd information (vaccination strategy adopted in the farm and veterinarian's perception of the farm's reproductive performance) and individual information (calving date, number of lactations, date of

vaccination and type of vaccine administered to the dam) were recorded. Cocygeal vein puncture using a vacutainer tube was used to draw blood. Antibody detection was achieved using 2 commercial IBR and BVD ELISA Kits. Sample processing and interpretation were performed according to the instructions of the manufacturer. In order to confirm that the samples were collected before colostrum intake, gamma-glutamyl transferase (GGT) activity was measured. As suggested by Paré et al., (1996), a sample with a GGT value < 50 U/L was considered to be precolostral.

Descriptive statistics were used to determine the distribution of the samples by farm, vaccination strategy and type of vaccine administered to the dams. The association between the IBR and BVD calf status and the type of vaccine given to the dam was analyzed using the Fisher's exact test. Results were considered to be statistically significant if P<0.05.

Results: A total of 304 samples were confirmed to be precolostral (PS). Out of them, 259 were collected from calves born from vaccinated cows (VC): 176 cows with an inactivated (K) vaccine and 83 cows with a modified live virus (MLV) vaccine. Overall, more positive results to either IBR (OR=86; 95% CI: 17.8 to 415.7) or BVD (OR=199.3; 95% CI: 41.7 to 952.3) were obtained within the non-PS than within the PS. Within the PS, 7 samples were positive either to IBR or BVD or both. One sample was positive to both IBR and BVD, 2 samples were positive only to IBR, and 4 samples were positive only to BVD. All positive PS were collected from calves born from VC, while positive non-PS originated mostly (60%) from calves born from non-VC. Five samples were collected from calves born from cows vaccinated with an inactivated (K) vaccine while 2 samples were collected from calves born from dams vaccinated with a modified live virus (MLV) vaccine.

Among the non-PS, 11 samples were positive to either IBR or BVD or both. Five samples were positive to both IBR and BVD, 1 sample was positive only to IBR and 5 samples were positive only to BVD. Seven samples were collected from calves born from non-vaccinated cows while the remaining 4 samples were collected from calves born from vaccinated cows (3 cows with a MLV vaccine and 1 cow with a K vaccine).

Conclusions: Positive results among PS indicate calf exposition to the viruses in utero. Positive results among non-PS reflect the presence of antibodies against both viruses in the dams. When samples are collected from calves born from non-VC, one could hypothesize that viruses are circulating in the herd. Precolostral sampling is a practical monitoring tool to determine and monitor IBR and BVD herd status in field conditions. Confirmation of precolostral samples by GGT activity level provides additional confidence in this strategy.

P04-004-171

Effects of Insemination Number and Days Postpartum on the Probability of Pregnancy at Insemination on Dairy Herds in the United Kingdom

Stuart Russell¹Helen Williams²Dai Grove-White²

¹Nantwich Farm Vets, Nantwich, ²School of Veterinary Science, University of Liverpool, Neston, United Kingdom

Objectives: Dairy herd fertility management is under increasing scrutiny in the European Union. Some conventional milk buyers are stipulating strategies that require selection of a subfertile population of cows before

hormonal intervention begins. Under management practices common in dairy herds in the United Kingdom, this study was designed to investigate how insemination number and days postpartum affect the probability of pregnancy at any given insemination, both at the cow and herd levels.

Materials and Methods: Milk recording data from National Milk Records (Wiltshire, UK) or the Cattle Information Service (Hertfordshire, UK) were collected from 240 dairy herds across the United Kingdom that had enrolled in a herd performance and monitoring scheme. Inseminations between 1st January 2012 and 31st December 2014 were included in analysis alongside corresponding testday milk records. Data were collated in DairyComp 305 (Valley Agricultural Software, USA) before being exported to Stata 13 (Statacorp, USA). Data were cleaned to exclude periods during lactations where the reliability of outcome or insemination data may bias the observed probability of pregnancy. A multilevel logistic model with a repeated measures structure (insemination within cow within herd) was fitted using a Markov-chain Monte Carlo approach with uniform priors (MLwiN 2.34; Centre for Multilevel Modelling, University of Bristol). The final model included insemination number, days postpartum, interservice interval, milk yield, calendar year, lactation group, linear somatic cell score (LSCOR) and four harmonic regression covariates to account for seasonality. Point estimates and ranges for average marginal effects of combinations of variables were obtained by simulation from the posterior distribution.

Results: The cleaned dataset contained 248,488 inseminations from 103,547 lactations in 66,388 cows on 228 herds, with 2,743 8th inseminations. Median herd 305d milk yield was 9145kg (IQR: 8316-9890kg), with mean conception rates for 1st lactation, 2nd lactation and >2nd lactation of 35.2% (95% CI: 34.9-35.5%), 31.8% (95% CI: 31.5-32.2%) and 29.1% (95% CI: 28.9-29.4%) respectively. At the cow level, controlling for other variables, odds ratios for inseminations 2 to 5 were higher than the reference 1st insemination ($P < 0.001$), with a peak of 1.14 (95% CI: 1.08-1.20) at 4th insemination. Odds ratios for the 6th to 8th inseminations were not different from the 1st ($P > 0.05$). Inseminations between 42 and 49 days postpartum (inclusive) had lower odds of pregnancy than the reference 50-70 day window ($P < 0.001$), corresponding to a 5.3% (95% CI: 3.9-6.7%) absolute difference in probability of pregnancy, assuming a baseline of 35%. The pattern of interservice intervals changed by both days postpartum and insemination number, emphasising their confounding effect in this study. At the herd level, observed cow-level residual error in the eligible population changed by both insemination number and days postpartum. Accounting for these changes there was a downward trend in probability of pregnancy by insemination number, but only the 7th and 8th inseminations were significantly different from the first ($P < 0.05$). There were no significant changes in odds of pregnancy by days postpartum once the combined effects of milk yield, lactation group, LSCOR and the eligible population were considered.

Conclusions: The use of days postpartum or insemination number to identify dairy cows with a low probability of pregnancy at the next insemination was not supported by this study. For similar herds to those investigated, herd fertility protocols would appear to be misguided if they rely on self-selection of a subfertile population before hormonal intervention starts. However, this study did not investigate variation in the probability of insemination. Reduced probability of pregnancy for inseminations before 50 days should not be taken in isolation, and may suggest room for improvements in transition management. Analysis continues at the time of writing.

Comments: This study was pursued in partial fulfillment of an Alternative Residency with the European College of Bovine Health Management.

P04-004-172

Detection of Under-Recorded Inseminations, Poor Oestrus Detection Specificity, or Abnormally Low Conception Risks in Multiherd Datasets

Stuart Russell¹*Helen Williams²Dai Grove-White²

¹Nantwich Farm Vets, Nantwich, ²School of Veterinary Science, University of Liverpool, Neston, United Kingdom

Objectives: Under-recording of unsuccessful inseminations leads to a bias in the observed conception risk towards lower insemination numbers. At the extreme, a 100% conception risk would be observed for first insemination. This bias may occur through poor data collection or by use of a stock bull. Abnormally low oestrus detection specificity would bias probability of pregnancy towards higher insemination numbers. As part of a study investigating conception risks, a graphical outlier detection technique was used to identify herd-years where insemination data was unreliable.

Materials and Methods: Milk recording data from National Milk Records (Wiltshire, UK) and the Cattle Information Service (Hertfordshire, UK) were collected from 240 dairy herds across the United Kingdom that had enrolled in a herd performance and monitoring scheme. Inseminations between 1st January 2012 and 31st December 2014 were included in analysis alongside corresponding testday milk records. Data were collated in DairyComp 305 (Valley Agricultural Software, USA). Lactations were right-censored to exclude periods during lactations where data reliability of recorded inseminations may bias the observed probability of pregnancy. Using non-censored inseminations, annual average 21-d Insemination Risk (21-d IR), 21-d Pregnancy Risk (21-d PR) and Conception Risk (CR) were calculated for each calendar year in each herd (herd-year) using a standardised 50 day voluntary waiting period.

To detect herd-years for which insemination data may be missing or unreliable, robust multivariate outlier detection was performed in R 3.2.0 (R Core Team 2015) using an iterated reweighted minimum covariance determinant procedure. Herd-years were marked as outliers if apparent relationships between annual averages for 21-d PR, 21-d IR and CR were unlikely for the dataset ($p < 0.025$), after approximating the distribution of their robust Mahalanobis Distances with an F distribution. The three-dimensional distribution of all herd-years was examined graphically. Observed conception risks were compared with those calculated after exclusion of data affected by outlying herd-years.

Results: Before outlier detection the cleaned dataset contained 269,992 inseminations between 1st January 2012 and 31st December 2014 from 240 herds. These data were clustered in 688 herd-years, of which 56 were identified as outliers by multivariate outlier detection, although only six herds were identified as outliers in more than one year.

Two main clusters of outlying herd-years were identified; Given their respective 21-d PR, one group had high mean CR and low 21-d IR. This pattern would be expected if a herd were systematically under-recording inseminations, or used a stock bull extensively. A second group of outliers had low mean CR and high 21-d IR when compared with their 21-d PR. This might suggest that oestrus detection specificity was low, pregnancy diagnosis results were not reliably recorded, or another process was reducing conception risks at the herd level. For this group of outliers, under-recording of pregnancy diagnosis results could be excluded by matching inseminations to results. Robust multivariate outlier detection excluded biologically implausible mean conception risks and identified other problems in the dataset. The potential bias in conception risk by insemination number induced by outlier censoring was minimal after the first insemination.

Conclusions: Robust Multivariate outlier detection using 21-d PR, 21-d IR and CR has potential to assist epidemiological studies into factors affecting conception risk. Furthermore, it may provide valuable information to assist large animal practitioners both in troubleshooting herd fertility problems and identifying herds with unreliable data. However, calculations for 21-d PR and 21-d IR in this study excluded inseminations censored in initial data cleaning in order to maintain the relationship between these variables and CR, so absolute values for 21-d PR and 21-d IR do not reflect true herd performance. Analysis is ongoing at the time of writing.

Comments: This study was pursued in partial fulfillment of an Alternative Residency with the European College of Bovine Health Management.

P04-004-173

Incidence of false positive oestrus in pasture-based, seasonally bred cows

Nikki Husaarts¹Jirigala Menghe²Scott McDougall^{2*}

¹Animal Husbandry and Animal Care, HAS Hogeschool, 's-Hertogenbosch, Netherlands, ²Cognosco, AnexaFVC, Morrinsville, New Zealand

Objectives: In the seasonal breeding system employed within the dairy industry of New Zealand, there is a strong emphasis on maximising sensitivity of oestrus detection. However, where false positive diagnosis of oestrus occurs conception will not occur, and in the case where pregnancy is already established, there is a high risk of embryo loss. Some studies have reported false positive oestrus rates of greater than 30%. Hence the objective of this study was to determine the incidence of false positive oestrus events during the period of artificial insemination.

Materials and Methods: Cows (n=556) from 15 herds (average herd size = 388 (SE= 277) range = 130 – 290) were enrolled. Herds were visited on 2 to 5 occasions coincident with the visit of the artificial insemination technician. All cows presented for AI that day were enrolled. These visits occurred between the 2nd and 4th week of the AI periods for the herds. Milk samples (2 to 4ml from a single gland) were collected into a vial containing a preservative (13mg of potassium dichromate in 200µl). The progesterone concentration was determined using an ELISA (Ridgeway Scientific, Gloucestershire, UK). A false positive oestrus was defined as occurring where the progesterone concentration was >2.5ng/mL. The artificial insemination technician was also asked to score the ease of insemination and the degree of mucus on an ordinal scale. The data were described, graphed and the exact 95% confidence intervals were calculated (Stata version 13.0)

Results: The mean milk progesterone concentration was 0.5 (SD=0.91) ng/mL. A total of 13 of the 556 (2.3% (exact 95%CI=1.3-4.0%)) cows had milk progesterone >2.5ng/mL indicating a likely false positive oestrus detection event. Nine of the 15 (60%) herds had no false positive cows, although due to the small sample size in some herds the confidence around these estimates is wide. The within herd prevalence of false positives ranged from 0 (exact 95%CI=0-13.7%) to 10.7% (exact 95%CI=2.3-28.2%). Cows presented for a second insemination were nearly four times more likely to be a false positive oestrus than those presented for their first insemination (5/68 (7.3%) vs 4/212 (1.9%) for 2nd vs. 1st service, respectively; relative risk=3.9, P=0.03).

Conclusions: The prevalence of false positive oestrus events was less than 3%. However, false positive oestrus does not appear to be a major

risk factor for poor reproductive performance in the seasonal breeding system practised in New Zealand. The prevalence of false positive oestrus was higher in the second three weeks of the seasonal breeding program, than the first. The consequences of a false positive oestrus in the second 3 weeks, when a proportion of cows are likely to be pregnant, is likely greater than where false positive oestrus event and insemination occurred in the first 3 weeks when few cows were pregnant.

P04-004-174

Maternal heart rate dynamics during the second stage of labour in dairy cows

Stefanie Krieger^{1*}Peter Kanz¹Christine Aurich²Christina Nagel²Michael Iwersen¹Marc Drillich¹

¹Clinical Unit of Herd Health Management for Ruminants, Clinic for Ruminants, Department for Farm Animals and Veterinary Public Health, ²Artificial Insemination and Embryo Transfer, University of Veterinary Medicine, Vienna, Austria

Objectives: Determining the onset of calving and monitoring the progress of labour is a challenging and time consuming process. A peripartum around-the-clock observation is regarded as the best method to detect dystocia in time. As a result of individual differences in behaviour, a practical tool which can be easily used on farms with sufficient accuracy is still missing. Therefore, the purpose of this study was to collect data of heart rate variability (HRV) on the basis of interbeat interval (IBI) measurements during parturition, in order to identify characteristic patterns for the onset of labour and calving process in dairy cows.

Materials and Methods: The study was performed at the Teaching and Research Farm Kremesberg, University of Veterinary Medicine Vienna, Austria. For this study, the cows (n=31) were moved from the group pen to a single calving box approximately 6 days before the expected calving. The straw bedded boxes were equipped with a 24h operating digital video recording system. In addition, interbeat intervals were measured using a Polar Equine H3 heart rate sensor and a RS800CX watch (Polar Electro Oy, Helsinki, Finland). In order to observe the dam's behaviour and posture, the video recordings were retrospectively analysed from 1.5 hours antepartum until the expulsion of the calf. The main recorded events were: lying, standing and abdominal contractions during lying bouts. Initial fragmentary bouts were counted as a completed period. Coherent abdominal contractions (n≥3) were classified as visible signs of labour. In a first step, the IBI measurements have been displayed graphically and were observed for characteristic patterns. In a second step, these findings were matched to the video recordings to determine causalities. Finally, the heart rate events were compared to the classified videos used as the gold standard.

Results: Overall, 20 IBI data sets were recorded in an evaluable quality. In 19 data sets, visually detectable patterns were found, shown as periodically appearing decelerations. Within these phases, the heart rate graph displayed v-shaped oscillations, varying in number, frequency and amplitude of the spikes. The decelerations appeared simultaneously to active phases of expulsion and every single spike occurred during an abdominal contraction. While evaluating the heart rate events, the highest correlation was found between two encoded events: visible signs of labour, and appearing spikes, both being present during the last lying bout before the expulsion of the calf. It can be assumed that the decelerations occurred during uterine contractions and, moreover, the amplitude of the spikes were related with the intensity of the

labour, which can be explained by the Frank-Starling mechanism and sympathetic activation.

Conclusions: The preliminary results of this study illustrate the potential of the use of the maternal heart rate as a peripartum monitoring parameter. Further data analyses and research is needed to prove these findings and to evaluate a new peripartum supervising system. A real-time heart rate based monitoring program could reduce calf mortality by providing an optimized calving management.

Therapeutic Evaluation of a Treatment Regimen in Dairy Cows with Acute Puerperal Metritis and Post Treatment Reproductive Performance

Abid Hussain Shahzad¹

¹Clinical Studies, University of veterinary and Animal Sciences Lahore, LAHORE, Pakistan

Objectives: Acute puerperal metritis (APM) is defined as a condition with an abnormally enlarged uterus and fetid, watery, reddish-brown uterine discharge, associated with systemic illness and fever within three weeks of calving. It is one of the major problem faced by dairy enterprises. Incidence rate ranges from 20-40%. Present study was conducted on a commercial dairy farm in from January, 2014-June, 2014. The objectives of this field study were to assess the diagnosis and a treatment regimen in dairy cow affected with APM and subsequent reproductive performance post treatment.

Materials and Methods: Totally 578 cows were routinely examined from day 2-15 postpartum. Cows were monitored for appetite and behavior on daily basis. Vaginal discharge was examined by vaginal inspection and rectal examination on alternate days. Cows with rectal temperature >39.5 °C, a large uterus with a thin uterine wall, fetid, watery, reddish-brown abnormal uterine discharge, when examined vaginoscopically, and loss of appetite were considered as APM positive cases. Cows not determined abnormal vaginal discharge, loss of appetite, depression, and with rectal temperature < 39.2 °C were considered as normal (without APM). Thirty cows with APM were enrolled in treatment group. Thirty cows without APM considered as control group with no treatment. Considering the life-threatening character of APM, no untreated control group consisting of APM was included in this study. Cows once diagnosed for APM were subjected to a treatment regimen consisted of Ceftiofur@ 2.2 mg/kg BW for 5 consecutive days intramuscularly from day 4th to 8th pp, intrauterine Cephapirin (500 mg) and prostaglandin I/M (25mg) on 15 day postpartum. Therapeutic cure of cows with APM was defined as the absence of fetid, watery, reddish brown abnormal uterine discharge examined on vaginoscopy, and disappearance of loss of appetite, depression, and the decrease of rectal body temperature (< 39.2) on day 6 after first ceftiofur administration.

Results: Data were analyzed using the SPSS. Independent sample t-test for parametric assumptions and Mann-Whitney test for nonparametric data were used for comparisons between groups. Fisher's Exact and chi-square tests were performed to test the differences between groups of categorical data ($p < 0.05$). Continuous variables were indicated separately according to the groups as means \pm SD. Vaginal discharge scores (VDS) for treatment (3.37 \pm 0.49, 2.37 \pm 0.93, 1.60 \pm 1.07, 0.37 \pm 0.67, 0.20 \pm 0.20) and control groups (1.40 \pm 1.13, 1.00 \pm 1.0, 0.27 \pm 0.64, 0.13 \pm 0.43) cows at different visit days (from V1 to V5) were calculated. Cervical and Uterine sizes (cm) for treatment and control groups cows at different visit

days. On visit V1 and V2 cervical diameter was 8.26 \pm 1.20 and 6.43 \pm 0.85 with corresponding control group having 4.87 \pm 0.77. Uterine horn (UH) diameter was 13.42 \pm 2.32 vs 12.51 \pm 1.03 in treatment and control group on V2 respectively. On Visit V5 uterine horn diameter was 5.76 \pm 0.61 in treatment groups as compared to 2.88 \pm 0.24 in positive control group. PMNs percentages on V2 were significantly higher in treatment group (48.17 \pm 10.07) as compared to control group (31.73 \pm 9.70). On V5 PMNs percentage was 4.10 \pm 5.74 in treatment group which was comparable with control one (4.67 \pm 6.17). First service conception rate was 40% and 43% in treatment and control group respectively. Pregnancy rate (87%) was comparable in treatment group with control one (90%) after overall inseminations.

Conclusions: Results of present study prove that systemic and intrauterine antibacterial therapy combined with prostaglandin has beneficial impact on reproductive performance in dairy cattle with acute puerperal metritis.

Reproduction: (Dairy)

P04-004-176

Evaluation of the effect of trace elements and vitamins boli on fertility parameters in dairy cows.

Celine Peudpiece¹Ruud De Gelas^{2,*}

¹R&D, ²R&D Export, Vetalis Technologies, Chateaubernard, France

Objectives: The costs of infertility can be very high for the farmer both in direct costs, like the multiplication of the number of artificial inseminations, as the hidden costs, more difficult to assess, such as loss of milk production or increase of the reform ratio due to infertility. The objective of this clinical trial was to evaluate the impact of a Vetalis bolus based on 5 trace elements (Co,Zn,Mn,I,Se), provitamins and vitamins (A,D3,E and beta-carotene), on the fecundity, particularly on the fertility of the dairy cattle. Beta carotene is an essential pre-cursor of vitamin A in the synthesis of progesterone from cholesterol by the corpus luteum.

Materials and Methods: 92 milk cows of the Prim Holstein race mainly, spread over 3 different farms with a different technical level have received a bolus on the day of calving in order to prepare the reproduction period. Group A, 49 cows, have received a placebo bolus, Group B, 43 cows have received a Vetalis bolus. Three parameters were investigated: interval calving - successful artificial insemination (parameter of fecundity), interval calving - 1st artificial insemination AI1, expressed in days and number of artificial inseminations (parameter of fertility). The products has been administrated under the supervision of the responsible veterinarian. A method of random alternating selection has been used to put up the different animal groups A and B.

Results:

- Study of the interval calving-fecundity insemination parameter (IC-FI)

On the IC-FI interval, we find a statistically significant herd effect, meaning a significant difference in between the herds X, Y and Z (Two factor ANOVA method- treatment and farm). Although no significant difference between the two groups A & B, neither in between the treatment effect on the herd, we can conclude an improvement after the use of the Vetalis bolus in the group B. Indeed, the IC-FI interval is 11 days shorter in group B compared to group A. This trend is even more important in the herd X, with a difference of 25 days in favor for the group that has received the Vetalis bolus.

- Study of the interval calving–first artificial insemination (IC_AI1)

We haven't distinguished significant differences between the treated group and the control group of animals on this parameter. The supplementation with the Vetalis bolus seems not to have influences of the heat detection in this study.

- Parameter "Number of artificial inseminations"

On the number of AI we observe a significant difference in between the 2 groups in favor for the group that has received the Vetalis bolus. PS : When the data are adjusted with a generalised linear model, the treatment effect is close to the threshold of statistical significance ($p=0.05972$). This effect becomes significant when we use a generalised linear model with mixed effect, meaning fixed and aleatory ($p=0.0484$). The herd effect is also significant (generalised linear mixed-effect model), meaning the number of AI is depending on the farm.

Conclusions: The results show that a supplementation with trace elements, vitamins and beta carotene have a statistically significant action on fertility and a clear tendency to improve the fecundity. The improvement of the number of inseminations is an average gain of 0,323 inseminations, meaning for a reproduction cycle of 21 days (theoretically in between 18 and 24 days), a gain of 6,9 days for the all farms and more precisely 16,6 days for farm X.

The bolus formulation, based on trace elements (Se,Zn,Mn,Cu,I), vitamins (A,D3,E; b-carotene precursor)occurs effectively in improving the fertility, even in non-optimal prescription conditions.

Comments:**- Estimated costs of a delayed in calving-calving interval:**

For an interval calving-calving longer than 400 days, the cost per delayed day is estimated at 3€(Verdoolaege, PLM) This means that in average, the use of a Vetalis bolus, saves 20,40€ per cow or 1032€ per herd with an average of 50,6 cows. The average AI-FI found in group A is 127 days. Taking in consideration a gestationperiod of 282 days, the calving-calving interval is 409 days in total. In the herd X, the supplementation with the Vetalis bolus has an economical gain of 49,80€ per cow, meaning 2520€ for a herd with an average of 50,6 cows. The interval AI-FI found in the herd X is 169,28 days, whether 450 days of calving-calving interval.

The results show that a supplementation with trace elements, vitamins and beta carotene have a statistically significant action on fertility and a clear tendency to improve the fecundity. This supplementation seems not to have influences on the cycle and the heat detection. On the other hand, we have noticed an action on the persistence of the gestation. According to scientific literature, the presence of a sufficient amount of beta-carotene is needed to complete the Vitamin A which is essential for a good growth of the corpus luteum and the local progesterone synthesis to attain an optimal plasmatic concentration. The progesterone promotes the elongation of the embryo and increase of the signal strength to maintain the gestation by the foetus. Beta-carotene and vitamin A are primary in the maintenance of the gestation. Vitamine E as Selenium are limiting the oxidative stress especially around ovulation. The trace elements are mainly involved in the hormonal system: I and Se in the synthesis of the thyroid hormones, Co and Zn rather the pituitary level.

The chelate form enables a direct assimilation in the bovine intestine, with a faster valorisation and efficacy of the Co Zn and Mn cations. Acting in synergy, they provide a support on the progesterone production and an increase on the fertility. The herd effect is important and allows us to assume an interesting action on farms with marked reproduction disorder as we can find in the farm X. This should be investigated in a new clinical trial on equal farms as farm X. The bolus was administrated at calving which is not the ideal timing for supplementation if we want to interfere with the reproduction period. However it is a strategic moment in the « field farm ». Indeed, we can assume that trace elements will be used to level up low trace elements concentration to address the needs

for calving preparation, placental transfer to the foetus and synthesis of colostrum. They will be less available for use in the context to improve fertility. We could consider exploring the trace element statutes before bolus administration and after his lead time. The interest was to demonstrate significant action even under non-optimal conditions.

Comparison of urine Pregnancy-associated Glycoproteins (PAG) and ultrasound as a specific method of late embryonic mortality diagnosis in dairy cows

Monika Petrajtis-Golobów¹, Noélita Melo De Sousa², Ricardo Faundez³, Jean-Francois Beckers², Zdzislaw Gajewski³

¹Department of Large Anim. Diseases, FVM, Warsaw University of Life Sciences (SGGW), Warsaw, Poland, ²Physiol. of Reprod. FVM, ULG, Liege, Belgium, ³Animal Reproduction, Andrology, FVM, WULS, Warsaw, Poland

Objectives: The aim of this study was to determine whether pregnancy-associated glycoprotein (PAG) concentration in urine of pregnant cows is as specific marker of late embryonic mortality (LEM) as ultrasound. For this purpose combine measurements of concentration of PAG in urine and transrectal ultrasonographic examination of the conceptus were performed.

Materials and Methods: The analyzed data were derived from 36 multiparous Holstein Friesian cows (BCS 3,25-3,5). Animals were divided into 3 groups: pregnant (P, n=16), non-pregnant (NP, n=10) and cow diagnosed with late embryonic mortality (LEM, n=10). Transrectal ultrasonographic examination and urine samples were obtained from all animals on days: 0 (AI day), 14, 21, 28, 35, 49, 63, 77, 91 and 105. Radioimmunoassay (RIA -706) was performed to determine cPAG (caprine PAG) concentration in urine. During the time all animals underwent pregnancy testing with B-mode diagnostic ultrasound Scanner (Mindray DP – 6600) equipped with a 7.5 MHz linear-array rectal probe and rectal palpation at each time point established. The diagnosis

of pregnancy indicates the presence of allantoic sac and the embryo presence, and after day 35 the heartbeat of the embryo. Late embryonic mortality or fetal death was diagnosed when observed embryo/fetus showed no heartbeat, or when previously observed embryo was not visible during subsequent ultrasound.

Results: The study of PAG concentrations in urine demonstrate an increased concentration of these proteins (>1,5ng/ml) in group of non-pregnant cows and cows with LEM. Identified low concentrations during pregnancy (<1ng/ml) in group of pregnant cows did not correlate with the period of pregnancy duration and varied more between individuals. In the context of late embryonic mortality diagnosis, PAG urine test proved to be as high sensitive and specific method as ultrasound examination.

The data obtained indicate the possibility of using PAG research in the urine as predictor of LEM. Marked significant differences occur as early as 5 weeks after insemination pointing to the high sensitivity and specificity of the method comparable to ultrasound. The accuracy of both tests at this time point was similar: sensitivity 98,3% for urine PAG, 100 % for ultrasound, specificity 90% and 98% respectively. Only the method of urine PAG analysis were able to detect pregnancy at stage of 28 day of gestation. (sensitivity 98% for PAG urine, 68% for ultrasound and specificity 90% and 70% respectively). However, by the end of the study the accuracy for ultrasound examination was 100% and for urine PAG method ranged between 75-100%.

Conclusions: Based on the study it can be concluded that the concentration of the PAG in the urine is a valuable source of information on the developing embryo / fetus. PAG concentration in urine is a sensitive indicator of pregnancy losses and requires further research to better understand and to develop methods for early detection of late embryonic mortality. In the context of late embryonic mortality diagnosis, PAG urine test proved to be as high sensitive and specific method as ultrasound examination.

High level of estradiol in sacroiliac luxation Holstein-friesian cow after calving

Yong-II Cho¹, Seogjin Kang¹, Taiseok Han¹, Seokki Im¹, Hyunjoo Lim¹

¹NATIONAL INSTITUTE OF ANIMAL SCIENCE, Cheonan-si, Korea, Republic Of

Objectives: Sacroiliac luxation was reported to occur rarely in cows during the periparturient period and high estrogen concentration was one of predispose through this phase. Prognosis is very poor because dystocia could not be avoided during calving period. The objective of the study is to serve the information to large animal practitioner that the case is rarely observed in the field.

Materials and Methods: A Holstein-Friesian cow was referred to animal clinic with unable to rise. The cow, on its fifth day after calving, had fallen on the slippery surface when it walked out from milking parlour after morning milking. It was moved to the soil ground by farm producers to prevent secondary injury due to the slippery floor and was crying in pain, with growling sound, for hours. Non steroid anti-inflammatory drug was injected into the cow to relieve the pain and antibiotic was restricted for preparation of the cow to be slaughtered.

Results: The next day, the cow was able to stand up after and regain its good appetite. The tuber coxa was quite raised above the lumbar vertebra and the gait posture of the hind limbs was rather unstable swing

back and forth. The estradiol(E2) level of the cow was high (average E2 concentration: 167 pg/mL) compared to those with normal standing posture (average E2 concentration: 41.4 pg/mL) within the same barn. The high E2 concentration continued for several days after the onset of the disease. Similarly, CK(creatine kinase), AST(aspartate aminotransterase) , LDH(lactate dehydrogenase) were also high in range while both the calcium and phosphorous levels were within the normal range as revealed by the blood chemistry analysis.

Conclusions: In conclusion, the cow finally was slaughtered due to the gait posture became more worsen though the cow had maintained good appetites. It would be presumed that the cow showed typical sacroiliac luxation after calving associated with the high level of E2 concentration.

Can in practice the success of insemination be predicted with a systematic assessment of the heat?

Marc Kirchhofer¹, Léonie von Tavel²

¹privat, ²Swissgenetics, 3033 Wohlen, Switzerland

Objectives: The success of insemination depends on several factors. It includes hosing of the bull, semen handling as well while the straw production as the insemination and the cow ready to conception. The quality of estrus of all cows inseminated by Swissgenetics SG will be evaluated with a simple system. Findings of an assessment of the cow at time of insemination are required to predict the probability of conception from the inseminated cow. The second aim of this assessments is to calculate the factor cow in the calculation of the nonreturnrate NNR of the bull and to estimate their influence in the work of the inseminator.

Materials and Methods: The records of all inseminations registered at SG from 07.01.2013 to 30.06.2014 were evaluated. The results of estrus assessments were compared to the NNR at day 56 post insemination. The following for criteria were assessed 1. information by the farmer: good heat, weak heat, Instruction by the veterinarian, no information. 2. rating of the point in time by the inseminator: in time, rather early, rather late, unclear signs . 3. findings of the sex organs: normal, large uterus, obscure mucus, urovagina, suspected cyst. 4. special findings: intravaginal device, other hormonal control, induced ovulation, other treatment by the veterinarian. Evaluations were made using excel.

Results: In the observation period total 835'281 inseminations were performed. 710'544 were performed by inseminators of SG and reported according to internal directives. Private veterinarians inseminated 124'736 cows. These are not required to assess the estrus; therefore from these there are no further information on estrus while insemination. The NNR 56 considering all inseminations was 69.78%, while the insemination success between inseminator (69.79%) and veterinarians (69.08%) was not significantly different. Were the heat qualitatively good and the time optimal assessed (610'566), the insemination success (70.93%) was significantly better than over all inseminations. The insemination success of a cow at earlier insemination in a good heat was not unfavorable affected (NRR 68.61 %). The other hand, a cow with an urovagina, their NRR dropped to 61.73 % although good estrus signs. Basically, a hormonal treatment for estrus induction reduces the NRR of less than 64%. However, showed the treated cows good estrus signs and the organs were assessed to be normal, the NRR (67.18%) of those cows were no longer differed from the average. Were findings assessed as different from the physiological properties, the NRR decreased: an enlarged uterus diminished the NRR to 60.42 % and a reduced NRR followed of changes in vaginal fluid (59.88 %).

Conclusions: The result shows, in practice a structured assessment of estrus signs before insemination is very useful. A possible success and especially failure of the insemination can be estimated. For a more differentiated expectation, the combination of different findings is important. Subsequently, calculation of the NRR, therefore the factor cow can be considered by systematic assessment of the heat. This more accurate calculation allows a differentiated evaluation of the quality of bull semen and the work of the inseminator.

Comparison of urine Pregnancy-associated Glycoproteins (PAG) and ultrasound as a specific method of late embryonic mortality diagnosis in dairy cows

Monika Petrajtis Golobow^{1*}Ricardo Faundez²Bartosz Pawlinski¹Zdzislaw Gajewski²

¹Dep. of Animal Reproduction, Dep. of Animal Reproduction, Warsaw University of Life Sciences, ²Dep. of Animal Reproduction, FVM, Warsaw University of Life Sciences, Warsaw, Poland

Objectives: The aim of this study was to determine whether pregnancy-associated glycoprotein (PAG) concentration in urine of pregnant cows is as specific marker of late embryonic mortality (LEM) as ultrasound. For this purpose combine measurements of concentration of PAG in urine and transrectal ultrasonographic examination of the conceptus were performed.

Materials and Methods: The analyzed data were derived from 36 multiparous Holstein Fresian cows (BCS 3,25-3.5). Animals were divided into 3 groups: pregnant (P, n=16), non-pregnant (NP, n=10) and cow diagnosed with late embryonic mortality (LEM, n=10). Signs of oestrus exhibition day was the "0" day. In P and LEM group AI was then conducted. Transrectal ultrasonographic examination and urine samples were obtained from all animals on days: 0 (AI day), 14, 21, 28, 35, 49, 63, 77, 91 and 105. Urine was obtained by catheterization. Blood was sampled from the tail vein (v. caudalis mediana). Samples has been deep-frozen and storage until analyses. RIA (RIA -706) was performed to determine cPAG (caprine PAG) concentration in urine. For the analysis of urine material, a modification of the method RIA III developed for the testing of PAG in milk with larger volumes of the test material was used. During the time all animals underwent pregnancy testing with B-mode diagnostic ultrasound Scanner (Mindray DP – 6600) equipped with a 7.5 MHz linear-array rectal probe and rectal palpation at each time point established. The diagnosis of pregnancy indicates the presence of allantoic sac and the embryo presence, and after day 35 the heartbeat of the embryo (Szenzi et al., 1998). Late embryonic mortality or fetal death was diagnosed when observed embryo/fetus showed no heartbeat, or when previously observed embryo was not visible during subsequent ultrasound.

Results: In contrast to the C group, the breakdown statistically different groups was not possible, the results of a group of LEM divided into two groups differ significantly depending on the time of the material collection: Group A (0 - 5 weeks after insemination), group B (7 - 11 weeks after insemination).

It was found no statistically significant differences between the PAG concentrations in the urine in study groups between 0 and 4 weeks after insemination. At 5, 7, 9 and 11 weeks after insemination we observed a statistically significant higher levels of PAG concentration in urine of

the cows from LEM group compared to P group. From 5 weeks after insemination it was observed directly proportional increase in the concentration of PAG in the urine of LEM cows until the end of the study. Cows diagnosed with late embryonic mortality at 5 weeks were higher than 1.5 ng / ml. The data obtained indicate the possibility of using PAG research in the urine as predictor of LEM. The accuracy of both tests at this time point was similar: sensitivity 98,3% for urine PAG, 100 % for ultrasound, specificity 90% and 98% respectively. Only the method of urine PAG analysis were able to detect pregnancy at stage of 28 day of gestation. (sensitivity 98% for PAG urine, 68% for ultrasound and specificity 90% and 70% respectively). However, by the end of the study the accuracy for ultrasound examination was 100% and for urine PAG method ranged between 75-100%.

Conclusions: Based on the study it can be concluded that the concentration of the PAG in the urine is a valuable source of information on the developing embryo / fetus. PAG concentration in urine is a sensitive indicator of pregnancy losses and requires further research to better understand and to develop methods for early detection of late embryonic mortality. In the context of late embryonic mortality diagnosis, PAG urine test proved to be as high sensitive and specific method as ultrasound examination.

Correlations between the volume of the corpus luteum and plasma concentration of progesterone in the estrous cycle of the cow.

Beatriz Alegre¹Judit Tejero¹Cristina Gomez¹Jose Ramiro Gonzalez-Montaña¹Marta E. Alonso²Julio Prieto²Juan Carlos Dominguez F. Tejerina^{1*}

¹Medicine, Surgery and Anatomy Veterinary, ²University of León, León, Spain

Objectives: The aim of present research was to evaluate the correlation between morphology and the volume of the corpus luteum with progesterone levels in the blood plasma of the reproductive cycle in dairy cows (Holstein-Friesian).

Materials and Methods: Ultrasound scans were carried out every 48 hours, using an ultrasound Sonovet 2000, with a multifrequency probe LV4-7AD designed to transrectal insertion. Several discriminative parameters of gestation (major and minor diameters of the corpus luteum, area and volume) were studied. In addition, progesterone levels in plasma, obtained of venous blood, was determined radioimmunologically using Spectria kits (Orion, Diagnostica, Finland). The limit of assay sensitivity was 94 pg/ml. The coefficients of variation within and between assays were 5.8 and 2.9% respectively. The mean recoveries were 95.4-104.2%

Results: Until the day 10 of the cycle, the luteal volume and concentration of plasma progesterone have been increasing. The growth rate of luteal volume is greater than the growth rate of the plasma progesterone in this period. However, from day 11 to 17 of the cycle, progesterone values which increases more sharply. Since the day 17, it begins to be sensitive process of luteal regression, down the values of luteal volume and plasma progesterone. The drop in progesterone levels is much faster and charged, especially between 20 and 21 drops to almost baseline levels.

Conclusions: It has been found that up to day 10 of the cycle, both the volume of the corpus luteum, as the concentration of plasmatic progesterone have increased. In this growth period, luteal volume is

greater than the growth plasmatic progesterone. From day 11 to 17 of the cycle, progesterone values increases more sharply. However, between 20 and 21 days, progesterone levels fall quickly, reaching baseline values.

Virulence factors profile and determination of phylogenetic group of *Escherichia coli* isolated from the uterus of Holstein cows in early postpartum

Luana C. Bicudo¹, Eunice Oba², Sony D. Bicudo², Domingos D. S. Leite³, Amanda K. Siqueira³, Meghi Nogueira³, José C. D. F. Pantoja⁴, Fernando J. P. Listoni⁴, Márcio G. Ribeiro⁴

¹Department of Animal Reproduction, University of São Paulo, São Paulo, ²Department of Animal Reproduction and Veterinary Radiology, São Paulo State University, Botucatu, ³Department of Genetics, Evolution and Bioagents, University of Campinas, Campinas, ⁴Department of Veterinary Hygiene and Public Health, São Paulo State University, Botucatu, Brazil

Objectives: This study aimed to evaluate pathogenic potential of *E. coli* involved in the uterine contamination on first days postpartum of healthy cows by the identification of virulence factors and phylogenetic grouping.

Materials and Methods: Data were collected from a dairy farm located in Araras, Brazil, on 75 Holstein cows with a mean age of 2.9 years (± 1.4), between first to sixth parity order, with normal calving and physiological puerperium, free from treatments with antibiotic or anti-inflammatory drugs during the experimental period of 14 days. Samples of uterine contents were collected 24 hours (Moment 1) and 14 days postpartum (Moment 2) for bacteriological analysis. All samples were cultured in MacConkey agar in aerobic conditions at 37°C for 48 hours aiming the isolation of *E. coli*. This bacterial specie was confirmed by the biochemical profile on the tests of glucose fermentation, gas production, L-TD (L-tryptophan deaminase), H₂S, urease, Simmons citrate, lysine, motility and indole. In all isolated *E. coli*, were investigated genes associated with virulence factors by Polymerase Chain Reaction (PCR). DNA extraction of *E. coli* strains was performed by boiling and centrifuged at 9676.8xg/2minutes, the supernatant was collected and refrigerated. Specific primers were used to amplify genes encoding virulence factors of adhesin of type 1 pili (fimH), S fimbriae (sfa), fimbriae P (papGI, papGII, papGIII and papC), K99 pilus (k99), afimbrial adhesin (afa), cytotoxic necrotizing factor type 1 (cnf-1), α -hemolysin (hlyA), verotoxin (vt1 and vt2), intimin (eae), uropathogenic specific protein (usp), K capsule (kps), and aerobactin (iucD/aer). To determine the phylogenetic group (A,B1,B2 or D) of *E. coli* strains were used the results of PCR amplification of the chuA and yjaA genes and DNA fragment TSPE4.C2.

Results: *E. coli* was isolated in 35 cultures at Moment 1 and in 24 cultures at Moment 2. Frequencies obtained for fimH, iucD/aer, kps, hlyA, usp, vt1, and vt2 genes were, respectively, 91,4%, 25,7%, 20,0%, 17,1%, 8,6%, 2,9% and 2,9% at Moment 1 and 79,2%, 25,0%, 4,2%, 12,5%, 4,2%, 0% and 4,2% at Moment 2. Sfa, papGI, papGII, papGIII, papC, k99, afa, cnf-1, and eae genes were not detected in any Moment. Distribution of *E. coli* phylogenetic groups in Moment 1 was 54,3% A, 31,4% B1, 0% B2, 14,3% D and in Moment 2 was 58,3% A, 33,3% B1, 8,3% B2, 0% D.

Conclusions: *E. coli* isolated from the uterus until the second week postpartum show virulence factors genes for adhesin of type 1 pili, aerobactin, K capsule, α -hemolysin, uropathogenic specific protein and verotoxin, and belong mainly to phylogenetic groups A and B1. Although

commensal strains, generally, belong to these phylogenetic groups, the presence of several virulence factors may favor the development of uterine infections in a later period depending on the immune status of the cow.

Comments: This work was conducted under the supervision of the ethical use of animals FMVZ-UNESP (protocol number 064/2012).

Distal Paravertebral Block for Left Flank Unilateral Ovariectomy in Cattle

Zdzislaw Gajewski¹, Katarzyna Siewruk², Michał Trela³, Ricardo Faundez⁴, Bartosz Pawlinski³, Michał Dabrowski³, Barbara Lisowska⁵

¹Dep. of Animal Reprod, CBB, WCB, Warsaw University of Life Sciences, ²Department for Animal Reproduction, ³Dep. for Animal Reproduction, WCB, CBB, ⁴Dep. for Animal Reproduction, FVM, Warsaw University of Life Sciences, ⁵Anesthesiology and Intensive Care Department, Independent Public Hospital them. Prof. Adam Gruca CMPK in Otwock., Warsaw, Poland

Objectives: Although general anaesthesia is used in cattle, there are some risk with using general anaesthesia. Local or regional anesthesia is safe, effective, and still the most desirable procedure in many situations. Many surgical procedures including unilateral ovariectomy can be performed safely in cattle using a combination of physical restraint, mild sedation, and local or regional nerve blocks. The aim of the study was to obtain the luteal tissue from ovary while defined oestrus cycle time for early pregnancy factors identification with precise molecular biology tools for early embryonic death prophylaxis.

Materials and Methods: The 10 Holstein-Friesian type cows during induced oestrus cycle were enrolled into the study. The elective, surgical procedure under distal paravertebral nerve block was performed in all animals. The distal paravertebral nerve block (between Th13 and L3 vertebra) following pharmacological sedation with xylazine 5-30 mg/100 kg (Xylapan 20mg/ml, Vetoquinol Biowet) combined with physical restraint was performed before left flank ovariectomy. The ovaries were removed to obtain luteal tissue for further detailed examinations. The postoperative antibiotic therapy with procaine benzylpenicillin 1ml/30 kg (Penillin 30%; 300 mg/ml; ScanVet Poland) in combination with postoperative analgesia flunixin 2ml/45kg (Flunimeg 50mg/ml; Scanvet Poland) was proceeding for 3 following days.

Results: No scoliosis and pelvic limb weakness were observed during surgery. Moreover no recumency occurred. Distal paravertebral nerve block provides great quality, unilateral analgesia of the paralumbar fossa for flank laparotomy being alternative to the inverted L block. This block provides uniform desensitisation of the peritoneum than is field infiltration, and also provides relaxation of the abdominal wall. For unilateral ovariectomy, this technique does not risk development of haematomas at the operating site. No general side effects including hypotension or respiratory paralysis were observed after lidocaine administration.

Conclusions: Local anesthetic techniques are usually simple, inexpensive and provide a reversible loss of sensation to a relatively well-defined area of the body including left flank region. Regional or local anaesthesia is safe, effective, and still the most desirable procedure in many situations because standing position in cattle is the best for surgical procedures including unilateral left flank ovariectomy. Properly performer blocks do not desensitize femoral and ischial nerves, thereby preserving pelvic limb function.

Preselection of high and low ovulatory responders for embryo transfer programs in goats

Mario Balara¹*Felipe Z. Brandão²Ana Lucia R. S. Maia¹Joanna Maria G. Souza-Fabjan¹Marcela Cueto³Alejandro E. Gibbons³Jeferson F Fonseca⁴

¹Clinical and Animal Pathology, ²Universidade Federal Fluminense, Niteroi, Brazil, ³Instituto Nacional de Tecnologia Agropecuaria, Bariloche, Argentina, ⁴Embrapa goats and sheep, Coronel Pacheco, Brazil

Objectives: This study aimed to evaluate the feasibility of establishing a pre-selection test by the use of low dose of eCG to identify does as high or low responders, prior to the use of a multiple ovulation FSH treatment. Concomitantly, the effect of follicular status at the beginning of eCG and FSH-superovulatory treatments and their relationship with the number of corpora lutea obtained was assessed.

Materials and Methods: The study was carried out in a dairy farm at Minas Gerais, Brazil. Twenty Saanen does received 800 IU of eCG at the end of long-term progestagen treatment. Fourteen days later, a second progestagen protocol associated with a multiple-dose FSH treatment (5 IU/kg of FSH, in six decreasing doses between Days 4 to 6 of the protocol) were administered. Transrectal ultrasound was used to assess the ovarian status at the following time: (1) previous to superovulatory treatments to quantify the number of small (2-4 mm), large (>4 mm) and total follicles; (2) onset of estrus behavior to quantify the large follicles; and (3) 7th day of the estrous cycle to quantify the number of corpora lutea (CL). The median of the number of CL per treatment was used as cut-off point for eCG (high ≥ 7 ; low < 7 CL) and to FSH treatments (high ≥ 23 ; low < 23 CL) to characterize the goat donors in high or low ovulatory potential. Other cut-off point was adopted just to compare the number of CL between treatments from goats with a lower number of large follicles (eCG: 5.4; FSH: 4.4) at the onset of the superovulatory treatment. Regression analysis and Pearson correlation coefficient were applied to assess the relationship between the number of CL and follicular status in treatments. The Spearman's rank correlation coefficient and Kappa coefficient were used to evaluate the relationship between high or low ovulatory responder does after each treatment. For all tests, $P < 0.05$ was considered as statistically significant.

Results: Positive correlations were obtained between the number of small follicles at first eCG/FSH dose with the number of CL ($r = -0.47$; $P < 0.05$) as well as the negative correlation between the presence of large follicles at eCG dose and number of CL ($r = -0.44$; $P < 0.05$). Furthermore, positive correlations were also obtained between the number of large follicles at estrus onset with the number of CL (eCG: $r = 0.51$; $P < 0.05$ / FSH: $r = 0.70$; $P < 0.05$). A good multiple correlation between all collected follicular indexes (small follicles, large, total at the beginning of superovulation and large follicles at estrus onset) was obtained for predicting the number of CL ($r^2 = 0.86$; $P < 0.05$). The assessment of the follicular status, prior to superovulatory stimulus, was able to estimate about 50% ($r^2 = 0.48$; $P < 0.05$) in multiovulatory response. A significant relationship ($r^2 = 0.498$; $P < 0.05$) between the number of CL in response to each treatment was obtained from a quartic regression. From the correlation analyzed of preselected goats ($n = 6$), with a lower number of large follicles prior to hormonal stimulation, a linear equation was obtained between treatments ($r = 0.76$; $y = 34.98 - 0.54x$; $P = 0.07$). Overall, 14 does out of 20 still showed high or low response after FSH treatment (70%; 14/20). The Kappa ($k = 0.40$; $P < 0.05$) coefficient did show a moderate concordance regarding to donors to be classified as high or low responders between treatments. However, the Spearman coefficient ($r_s = 0.39$; $P = 0.08$) has just indicated a trend of relationship between them.

Conclusions: It was concluded that the screening protocol with eCG has the potential to identify Saanen goats that will better respond to the

FSH treatment. In addition, it highlighted the importance of an ultrasound assessment prior to the beginning of superovulation treatments with FSH in order to characterize the follicular status and identify potential donors with probable high ovulatory response for MOET programs in goats.

Comments: The results of this study will contribute to the improvement of the current indices obtained in MOET programs in goats. Furthermore, the Buiatrics congress arises as the site for propagation and discussion of the findings with the scientific community.

Answer Sheep Reproductive Synchronized with Progestogen Utilized Montas Addressed

Rodolfo Lucio Dominguez¹, Jose Luis C. Bedolla Cedeño², Victor M. Sanchez Parra², Valente Velazquez Ordoñez³, Leticia Sesento Garcia²

¹Produccion Animal, ²Production Animal, Faculty of Veterinary Medicine and Animal Science of the University Michoacana of San Nicolas of Hidalgo, MORELIA, MICHOACAN., ³CIESA, University Autonomous of State of Mexico. Toluca. Mexico, TOLUCA, MEXICO, Mexico

Objectives: The aim of this study was to evaluate the response to estrus and treatment costs by comparing two sources of progestogen (progesterone + prostaglandin vs melengestrol acetate (MGA)) in two synchronization protocols

Materials and Methods: 30 sheep were used in the study, which were divided into two batches (L1 and L2). Crosses of Dorper and Katahdin breeds were handled. From 3 to 4 years old, clinically healthy, with an average weight of 36.5 ± 38.2 kg and body condition of 2.5 to 3.5 on a scale of 0 to 5. The treatments were: Lot 1 (Protocol 9 days) was supplied progesterone (P4) on day 1, start of the protocol, with a dose of 0.75 ml IM + prostaglandin (PGF2a) on 9 IM with a dose of 0.75 mg / kg. It was allowed to proceed 24 hours and for the 10th of the protocol, a guard male (with a penis deflected) of the Katahdin breed was introduced, with an average weight of 36.5 ± 37 kg and body condition 3. Lot 2 (Protocol 9 day): melengestrol acetate (MGA) at a dose of 1 mg, and a concentration of 0.44%, orally, following supply MGA was supplied was allowed to elapse 24 hrs, to introduce the male guard (with penis off target) in the Katahdin breed he was introduced Once the male guard a certain number of days (4 days) was given to the sheep come into estrus in both protocols.

Results: Differences between the two treatments synchronization protocols in the proportion of ewes entered in heat were observed. Lot 1. Of the 15 sheep treated with P4 + PGF2a in this batch, 7 ewes in estrus while the remaining 8 are not presented. The zeal occurred in an average of 66 hours \pm 30 hours. Lot 2. Of the 15 sheep treated with MGA (melengestrol acetate) 12 had zeal, while the remaining 3 did not show. The zeal occurred in an average of 45 hours \pm 28 hours. Results for percentage of estrus in the operation were significantly different, was obtained for the protocol P4 + PGF2a, a percentage of zeal was 46% and for MGA 80% was obtained. The final treatment interval of estrus in both groups, was a great difference between them, that because the P4 + PGF2a protocol progesterone (P4) is given on day 1 + prostaglandin (PGF2a) on 9 while the AMS was supplied for 9 consecutive days.

Conclusions: Which it concludes the estrus synchronization with melengestrol acetate (MGA) in sheep reproductive induce Positive answers if is APPLY of a high concentration (1 mg / ewe), this benefit producers due to a cost under the (\$ 3.5) Do estrus and Response. While progesterone + prostaglandin has a low reproductive response, if is applies

Concentrations low (0.75 ml P4, prostaglandin 7.5 mg / kg), combined with poor nutrition of (stubble / oats) and Poor body condition 2.5.

Evaluation of cardiorespiratory parameters in Santa Ines sheep undergoing side access laparoscopic ovum pick-up

Renata S. G. Mariano¹Ricardo P. Nociti¹Ricardo A. R. Uscategui¹Felipe F. P. D. C. Barros¹Luciana Cristina P. Nakaghi¹Victor José C. Santos¹Mariana G. K. Rodriguez¹Pedro Paulo M. Teixeira²Wilter Ricardo R. Vicente^{1*}

¹Unesp-Universidade Estadual Paulista/FCAV, Jaboticabal,

²Universidade Federal do Pará, Castanhal, Brazil

Objectives: The laparoscopic ovum pick-up (LOPU) is widely used in reproductive biotechnology, although this intervention produce physiological changes in the cardiorespiratory system due to Trendelenburg position and CO₂ pneumoperitoneum. Aiming to decrease these problems we development a new surgical approach in the lateral position for follicular aspiration.

Materials and Methods: Twenty-four Santa Ines sheep were randomly divided into two groups with 12 animals: GL - positioned in right lateral position and head down position of 10 degree; GD – supine positioned and an head down inclination of 35 degree. The animals were submitted to LOPU procedure, with 36 hours fasting (hydric and solid), without hormonal treatment, using three portals and CO₂ pneumoperitoneum. The heart rate (HR, beats/minute), respiratory rate (RR, cycle/minute), mean arterial pressure (MAP,mmHg) and pressure at the end of the exhaled CO₂ (EtCO₂) were evaluated in the surgical period.

Results: Lateral and traditionally surgical approaches evaluated in this study were effective for follicular aspiration. Cardiorespiratory parameters were affected by the surgical position being: the Hearth Rate (GL 98,3±3,3 and GD 111±3,6 beats/minute), Medium Arterial Pressure (GL 78±2,3 and GD 87,4±2,6 mmHg) and End Tidal CO₂ pressure (GL 37,3±1,2 and GD 42,5±1 mmHg) were higher in the GL group (p=0,009; p=0,012 and p=0,001 respectively) than in the GD group and the Respiratory rate (GL 40,9±2,1 and GD 36,7±2 mmHg) was similar between groups (p=0,9).

Conclusions: Technique in lateral recumbence for follicular aspiration presents as a viable and effective procedure for oocyte recovery in Santa Ines sheep. However, this access result in considerable cardiorespiratory system alterations when compared to the conventional procedure, making that practical applicability was limited

Activation of SIRT1 by resveratrol influences developmental competence of bovine oocytes in relation to maternal age

Paul Kordowitzki^{1,2*}Klaus-Gerd Haderl¹Doris Herrmann¹Patrick Aldag

¹Heiner Niemann¹

¹Department for Biotechnology, , Friedrich-Loeffler-Institut, Neustadt am Ruebenberge, ²Hannover Graduate School for Veterinary Pathobiology,Neuroinfectiology, and Translational Medicine, University of Veterinary Medicine Hannover, Hannover, Germany

Objectives: Maternal age affects the developmental capacity of mammalian oocytes and embryos. Sirtuins are critically involved in ageing associated pathways. SIRT1 belongs to the family of NAD⁺-dependent deacetylases, and it has been shown to regulate several key cellular processes, including transcriptional silencing and ageing. SIRT1 plays also a crucial role in sensing and modulating the cellular redox status. Resveratrol (3,4',5-trihydroxystilbene) is a phytoalexin identified in various plant species which enhances SIRT1 activity by inhibiting phosphodiesterase.

Materials and Methods: The goal of the present study was to examine the effects of resveratrol on SIRT1 gene expression profiles of bovine oocytes and embryos derived from donors of different age. Cumulus-oocyte-complexes of prepubertal (5-6 months old) and adult (2. lactation) cows were collected by Ovum Pick-up. Medium for in vitro maturation and in vitro fertilization was supplemented with 2µM Resveratrol® (Sigma-Aldrich, Buchs, Switzerland). Maturation rates, cleavage and blastocyst formation were evaluated. Comprehensive gene expression assays of germinal vesicle and metaphase II (MII)-stage oocytes and expanded blastocyst were conducted using next-generation sequencing technology.

Results: Relative mRNA abundance levels of SIRT1 were higher in in vitro-matured oocytes derived from cows than in those derived from their younger counterparts (2.8 fold change, p≤0.05). The gene-expression profiles in blastocysts derived from oocytes of the two types of donors showed no significant differences. However, resveratrol improved maturation rates (82.3±4 and 83.6±3 %) and blastocyst formation rates (26.4±3 and 28.7±2 %) in both donor groups compared to a laboratory typical protocol without resveratrol as a control (74.6±5 and 20.8 ±2%, respectively, p≤0.05).

Conclusions: In conclusion, expression profiles for SIRT1 of oocytes and embryos derived from adult donors differ from those of oocytes and embryos derived from prepubertal donors. In addition, activation of SIRT1 in bovine oocytes in relation to maternal age may be a potential indication for determining age-associated events in bovine oocytes.

Comparison of histology and cytology for diagnosis of bovine subclinical endometritis

Desiree Hartmann^{1*}Jacquelin Rohkohl²Sabine Merbach³Thomas Heilkenbrinker²Hans-Peter Klindworth²Heinz-A. Schoon³Martina Hoedemaker⁴

¹Farm Department, Hampden Veterinary Hospital, Aylesbury, Buckinghamshire, United Kingdom, ²Animal Health Department , Chamber of Agriculture Lower Saxony, Oldenburg, ³Faculty of Veterinary Medicine, Institute of Veterinary Pathology, University of Leipzig, Leipzig, ⁴Clinic for Cattle, University of Veterinary Medicine Hannover, Hannover, Germany

Objectives: Inflammation of the endometrium is a major cause of impaired fertility in the postpartum cow. Particularly, to identify subclinical

endometritis no reliable standardised diagnostic techniques are established. Therefore, it was the aim of this study to compare uterine histology (as the golden standard) and cytology (as a routine diagnostic tool) for diagnosis of bovine subclinical endometritis.

Materials and Methods: Dairy cows from 33 dairy farms were examined by rectal palpation and vaginoscopy at 42 to 50 d postpartum. Inclusion criteria were absence of abnormal vaginal discharge and abnormalities of the uterus (fluctuation) at rectal palpation. Cytobrush samples from the uterus were collected by a modified cytobrush® method. A minimum of 200 cells were counted to determine the percentage of neutrophils (PMN) as indicators of endometritis (thresholds: $\geq 5\%$). Furthermore, biopsy samples from the endometrium were taken using the biopsy forceps according to Kevorikan. Tissue samples were fixed in 4% formaldehyde, embedded in paraplast and stained with hematoxylin-eosin.

Results: Overall, from 277 animals, both types of samples could be obtained. Percent PMN $\geq 5\%$ was 25.9 (n=72). Histologically, endometritis was diagnosed in 105 cases (37.9%). Thirty-three (31.7%) of those samples had a PMN $\geq 5\%$. In 100 samples, a differentiation between purulent (n=91) and non-purulent endometritis was possible (n=9). Percent PMN $\geq 5\%$ was 77.8 vs. 27.5 for purulent vs. non-purulent endometritis (P<0.05). Compared with cows with a negative histological result, cows with non-purulent endometritis did not differ, whereas cows with purulent endometritis had a higher percentage of samples with $\geq 5\%$ PMN (P<0.05).

Conclusions: Our results suggest a relationship between % PMN in uterine cytobrush samples and histologically in diagnosed purulent endometritis. However, using uterine biopsy as the reference method to diagnose endometritis, the calculated sensitivity is just 31.4% and the specificity 77.3% for cytology with a threshold of $\geq 5\%$ PMN. Therefore, with uterine cytology no reliable diagnosis of non-purulent endometritis is possible.

SEMENRATE: Independent Assessment of Bovine Semen through CASA and Flowcytometry

Jonathan Statham¹, Katie Burton¹, Mark W. Spilman²

¹RAFT Solutions Ltd, ²Bishopton Veterinary Group, Ripon, United Kingdom

Objectives: Conventional parameters routinely examined in bovine semen assessment are concentration, progressive motility and morphology. However, this subjective approach used during quality control at SPCs or during investigations of poor reproductive performance in veterinary practice has been shown to be relatively inaccurate, imprecise and operator dependent (Vincent et al, 2012).

Analysis of semen in use on 50 dairy and beef farms using CASA and flow cytometry in a dedicated breeding laboratory in a veterinary practice aimed to establish variations in the multiple parameters and then evaluate the relationship to semen performance in the field.

Materials and Methods: The development of a new automated independent screening service for frozen and fresh semen, using computer assisted semen analysis (CASA) with flow cytometry (FC) is very new. Initial research was needed to determine the technology and service proposed provides reliable results, as the approach combines 2 emerging technologies (CASA and FC) in a previously unused way.

During this period of the project veterinary surgeons with recognised semen evaluation experience cross checked the results manually. This helps build a multi-parameteric database of results across the EU to enable analysis of the most significant factors to subsequent fertility outcomes on farm.

The 'SemenRate' service will provide farmers with accurate data on semen they purchase to compare and validate semen choice. A funded research study has provided the platform to launch the commercial semen analysis service.

- Stage 1 analysed frozen and freshly collected bull semen from 50 cattle farms against 5 parameters.
- Stage 2 compared analysis parameters to subsequent fertility performance on farm; this is ongoing in collaboration with 7 European countries.
- Stage 3 will extend a commercial service across the UK and EU for freshly collected bull semen, frozen semen collected via a national network of recognized breeding centres associated with XLvets veterinary practices and to semen from other species such as porcine or equine semen.

Results: Three groups of semen (AI frozen, fresh and AI sexed frozen) were assessed using 5 CASA and flow cytometry parameters. For frozen AI semen (n=49), % viable sperm (max=65.22, min=18.80, mean=43.86), % sperm with polarised (active) mitochondria (max=72.50, min=11.25, mean=39.33), % sperm with acrosome intact (max=68.82, min=10.34, mean=36.53), % motile sperm (max=63.80, min=13.10, mean=38.46) and % progressively motile sperm (max=51.60, min=3, mean=25.04).

For fresh semen 5 parameters were assessed (n=48), % viable sperm (max=89.94, min=10.3, mean=50.65), % polarised (active) mitochondria (max=91.56, min=4.3, mean=44.9), % sperm with acrosome intact (max=87.44, min=5.38, mean=41.79), % motile sperm (max=89, min=1.40, mean=47.51) and % progressively motile sperm (max=75.50, min=0, mean=35.65).

For frozen, sexed AI semen 5 parameters were assessed (n=9), % viable sperm (max=66.31, min=17.08, mean=43.57), % polarised (active) mitochondria (max=26.74, min=13.40, mean=19.96), % intact acrosome (max=52.62, min=15.34, mean=37), % motile (max=38, min=9.40, mean=24.88) and % progressively motile (max=22.80, min=3.90, mean=13.15).

Conclusions: An EU collaboration aims to establish correlations between semen quality parameters and fertility outcomes for UK dairy and beef herds providing unique data for British dairy and beef herds. This data should highlight to fellow stakeholders in the industry how imperative optimal semen quality is and highlight the benefits to herd fertility and financial performance.

SemenRate could be used: to screen semen pre ET/OPU-IVF programme; in Bull breeding soundness evaluations for repeatability and objectivity; to screen semen batches to minimise risk of reduced performance & when cold chain is risk high; and to investigate fertility issues.

Salmonellosis

P04-004-190

A rapid, robust molecular diagnostic test for bovine salmonellosis.Fredericka Mitchell^{1,2,3}* Gary Forster-Wilkins¹ Tim Potter³ James Denholm-Price¹ Matt Dobbs³ Mark Fielder¹¹Kingston University, Kingston upon Thames, ²AHDB Beef and Lamb, Kenilworth, ³Westpoint Veterinary Group, Horsham, United Kingdom

Objectives: *Salmonella enterica* is a zoonotic pathogen with a broad host range. *Salmonella enterica* serovar Dublin (S. Dublin) is host-adapted to cattle and causes significant morbidity. Infection with S. Dublin can result in long term carriage in cattle, abortion and a high mortality in calves. To enable targeted treatment at the point of decision making, a loop-mediated isothermal amplification (LAMP) assay for the detection of *Salmonellae* is being developed as part of a diagnostic platform. The proposed platform will be rapid, robust, reliable and cost effective in detecting *Salmonellae* in bovine faecal matter for ease of use.

Materials and Methods: To identify highly conserved genes across multiple *Salmonella* serovars, eleven complete salmonella genomes were aligned using a genome alignment software package (Mauve). Using the alignment and relevant literature a number of conserved genes were identified, of which three highly conserved genes were selected for polymerase chain reaction (PCR) primer development, using Primer BLAST. After extensive method optimisation, primer sets have been tested against a panel of eight salmonella serovars, using a no-template assay and *Escherichia coli* as a negative control. Utilising Primer explorer, LAMP primers are being developed for all three target genes using the sequences targeted by the PCR primers. All primers were run through a nucleotide BLAST search, excluding *Salmonella* sp., to test for the likelihood of false positives from the primer set. The matches were assessed by several criteria; whether both primers in a set match the same organism, how exactly the primers matched the genome of the organism and whether that organism is likely to be found in a UK cattle industry setting.

Results: Whilst a full screening of the Mauve alignment was not undertaken, 28 genes conserved across multiple salmonella genomes were found: 7 highly conserved genes were found to be salmonella specific. The 3 genes used for PCR primer development (*hilA*, *orgA*, and *bapA*) were chosen as they are highly conserved across multiple *Salmonella* species, with sparse differences in sequence, and *Salmonella* specific when analysed using BLAST. The *hilA* gene is located within the *Salmonella* Pathogenicity Island 1 (SPI1) and encodes a protein that controls the expression of invasion genes and is required for *Salmonella* to colonise the extracellular surface of the intestinal lumen of the host. The *orgA* gene is also located in SPI1 and encodes a protein involved in the formation of the type III secretion needle structure which aids invasion and secretion. Whilst the function of *bapA* needs further investigation, it is thought to have a role in biofilm formation.

Using the *hilA*, *orgA*, and *bapA* gene sequences 15 sets of PCR primers were generated; 5 per gene. After non-salmonella specific matches were assessed, 6 primer sets in total were chosen for production, 2 per gene. Through PCR it has been established that all 6 primer sets recognised multiple salmonella serovars, demonstrating that multiple *Salmonella* serovars can be identified by targeting these 3 genes.

Conclusions: A rapid, robust and reliable diagnostic platform allows targeted treatment of bovine salmonellosis at the point of decision making. Rapid diagnostics for salmonellosis potentially: reduces economic impacts of the disease; has public health benefits; reduces the spread of infection within herds and environment. Additionally animal welfare is improved as early diagnostics could facilitate the

implementation of targeted treatment so improving cattle health. This is opportune given that multidrug resistance is a worldwide problem. Targeted treatment of disease will promote antibiotic stewardship by reducing blanket treatment in cattle.

Small Ruminants

P01-001-082

The effect of antimicrobial treatment on faecal flora of goat kidsSarah Lais¹Andrea Mueller²Roger Stephan²Cedric Muentener³Ulrich Bleul^{1,*}

¹Department of Farm Animals, Clinic of Reproductive Medicine, Vetsuisse-Faculty University Zurich, ²Institute for Food Safety and Hygiene, ³Institute of Veterinary Pharmacology and Toxicology, 8057 Zurich, Switzerland

Objectives: The faecal flora of goat kids affected by the floppy kid syndrome consists more of streptococci/staphylococci, enterococci and lactobacilli than the faecal flora of healthy goat kids. Therefore it was suspected that these bacteria might be responsible for the D-lactate hyperemia causing the floppy kid syndrome. Reducing these bacteria might prevent the floppy kid syndrome.

In this study it was tested experimentally, if an oral dose of antibiotic changes the bacterial intestine bacterial microflora in goat kids.

Materials and Methods: Goat kids (n = 29), between 4 and 20 days of age, were randomly divided into three groups and every second day a sample of faeces and blood was taken during an 11-day observation period. Two groups were treated for seven days with two different antibiotics orally. In group T (n = 9) Tylosin, given in a dose of 25 mg per kg body weight twice a day, and in group B (n = 10) Bacitracin, given in a dose of 210 IU per kg weight twice a day, were chosen for antibiotic treatment due to their efficacy mainly against gram positive bacteria. Animals in group C served as controls (n = 10). Every day all kids were examined clinically. The total number of aerobic bacteria and the number of streptococci/staphylococci, of enterococci and of lactobacilli were analyzed in the faecal samples using spread-plate method with selective culture media. A geometric dilution series was used for calculating the number of bacteria per gram faeces based of the number of CFU. D-lactate, blood gas and acid-base parameter were measured in heparinized blood samples. For all groups of organisms, numbers of CFUs were not normally distributed, and therefore groups were compared using Mann-Whitney-U und Kruskal-Wallis tests. A log₁₀(CFU³) transformation was made to test differences over time using ANOVA for repeated measures.

Results: None of the analyzed bacterial groups showed the expected decrease in the amount during the observation period. The numbers of CFU differ neither over time nor between groups. Only on a few single test days significant differences between groups were measured, but in these cases the samples of the control group always showed a lower amount of tested bacteria than the faecal samples of the treatment group. There was no statistical coherence between the amount of bacteria and D-lactate, blood gas and acid-base parameter. None of the goat kids showed clinical signs of floppy kid syndrome. However, on day 0 seven of them showed a concentration of D-lactate > 3 mmol/l in the blood and the concentration decreased significantly until day 8 (p < 0.0001). Simultaneously the pH increased from 7.34 ± 0.071 to 7.42 ± 0.053 (p < 0.05).

Conclusions: The expected decrease of the analyzed bacterial groups due to the antimicrobial treatment was not measurable. The reason for the undetectable effect could not be found. The short duration of treatment, the selected antibiotics or a selection and subsequent growth of resistant bacteria may be possible causes. 24% of the goat kids showed signs of a D-lactate acidosis, which may also have an effect on the faecal flora. Hence, a prophylactic antibiotic treatment as used in this study could not be recommended to prevent floppy kid syndrome in neonatal goat kids.

P01-001-083

Effect of a 5-months lameness inspection and gamithromycin treatment on footrot in sheepSimon Rougegré¹Jean-Baptiste Del Marmol¹Benoit Bolkaerts¹Christine Baricalla¹Nathalie Kirschvink^{1,*}

¹Veterinary Medicine, University of Namur, 5000 Namur, Belgium

Objectives: Gamithromycin belongs to the macrolide antibiotics and is characterised by an important volume of distribution and accumulation in skin tissue (Kellermann et al., 2014). It represents an interesting treatment option against ovine footrot that is caused by *Dichelobacter nodosus*. First reports about field studies with short intervention periods describe successful reduction of lameness in affected sheep flocks (Forbes et al., 2014 ; Strobel et al., 2014). The present study describes the long term evolution of lameness and need for treatment in a sheep flock that underwent during 5 consecutive months a weekly lameness inspection.

Materials and Methods: Adult ewes and 4-7 months old ewe lambs of the Ovine Research Center (ORC) of the University of Namur (Belgium) were enrolled in this study (n=427). The sheep flock of ORC was affected by footrot with around 35% of the animals displaying moderate lameness affecting at least one limb. All sheep underwent once per week lameness inspection during which 8-12 animals were observed during 5 minutes. Lame animals received a single gamithromycin injection (6 mg/kg BW SC) and their ear tag number was recorded. The inspection period lasted from July to November 2015. The percentage of treated animals was analysed over time and in function of treatment frequency. 50 animals underwent regular footrot lesion scoring.

Results: 461 treatments were administrated over 7818 individual inspections performed during the observation period. At first week of inspection, 32% of sheep required treatment. During the following weeks, the percentage of treatment requiring sheep ranged between 0% (dry and hot conditions in July) and 15% (rainy conditions in October) with a mean percentage of 4.4% per week. Lameness severity strongly decreased and lesion scores of lame sheep were reduced by more than 50% (passing from a median score of 2 to 1). 33% of the animals did not require treatment during the observation period; 40% were treated once; 16, 8, 2 and 1 % required respectively 2, 3, 4 or 5 treatments.

Conclusions: This study demonstrates that regular lameness inspection and treatment with gamithromycin of lame sheep strongly reduces footrot incidence. However, this lameness-based approach does not allow definite eradication of footrot. Further investigations are necessary to test how eradication of the disease could be achieved, especially by considering sensitive animals requiring more frequent treatments.

Comments: The authors acknowledge Nicolas Noël and Martin Dieu for technical contribution to this study.

P01-001-084

Estimation of the influence of risk factors affecting ovine colostrum quality of high producing dairy Lacaune ewesFernando Hernandez¹Laura Torres-Rovira²Laura Elvira³Juan Vicente Gonzalez-Martin⁴Antonio Gonzalez-Bulnes²Susana Astiz^{2,*}

¹Granja Cerromonte, Ávila, ²Animal Reproduction, INIA, ³Technical Department, MSD AH, ⁴TRIALVET SL, Madrid, Spain

Objectives: Refractometry using a Brix refractometer has been demonstrated as a means to estimate IgG concentration in bovine maternal colostrum. The refractometer has advantages over other methods being inexpensive, readily available and less fragile, as it has previously confirmed in bovine and ovine colostrum. With the refractometer risk factors affecting colostrum quality can be measured on farm and help to take management decisions quickly.

Objectives: Our objective was to estimate ovine colostrum quality and its variation depending on risk factors declared to influence colostrum quality using an inexpensive Brix refractometer

Materials and Methods: Animals from one single commercial dairy Lacaune farm (4100 ewes; average milk yield per ewe per year of 450L) were included. We tested colostrum from 537 lambings during the years 2011-2013, from ewes with different previous dry period (PDP). A total of 118 were primiparous; 23 had a short previous dry period (0-30 days long); 214 had an adequate dry period (31-60d long); 134 had a long dry period (61-90d long) and 48 had a very long dry period (>90d); parity of the ewes ranged between first and 10th lambing (118 first lambing; 116 second one; 87 3rd one; 84 4th one and 132 ewes had ≥5th lambings); season was also taken into account comparing the lambings in the natural reproductive season (Dec-Aug) versus lambings occurring in the contra-natural lambing season (Sept-Nov). The influence of the age at first lambing was evaluated including the 118 primiparous ewes and separately analyzed. SPSS®19.0 (IBM, NY, USA) was used. The statistical significance of differences was assessed by ANOVA test and relationships between parameters were assessed by Pearson correlation analysis and non-parametric correlation tests.

Results: The average of dry period length was 65.1±41.5d and the age at first lambing 12.7±1.7 mo.

The length of the previous dry period significantly affected the quality on colostrum measured as percentage of solids expressed as percentage by the Brick refractometer. Ewes at first lambing (22.5±5.6%) and those with the longest PDP (20.9±6.3%) showed the maximal qualities (P<0.0001). Ewes with the shortest PDP had the worst quality 16.8±4.2% (P<0.0001). Ewes with an adequate PDP showed 18.7±4.4% and ewes with a long PDP 19.9±5.4%.

Parity significantly affected colostrum quality with the primiparous ewes showing the highest quality (22.5±5.6%; P<0.0001) followed by the ewes with ≥5th lambings (19.9±4.2%). The worst quality was observed by the 2nd lambing ewes (18.8±3.8%).

Year of study was significantly different, with 2011 showing a higher colostrum quality, because we had a bias of the percentage of animals with very long PDP during the year 2011 (21,1 in 2011 vs. 8.9% as average; P= 0.026), bias that was controlled in the analyse.

Lambing season did not affect colostrum quality (20.11±5.0% natural season vs. 19.7±5.7% contra-natural season; P=0.47).

Finally, the age at first lambing showed a quadratic significant relationship with higher colostrum values at the age at first lambing of ≤12mo and ≥15 mo of age (P= 0.012).

Conclusions: These results ratify risk factors such as parity, length of the previous dry period and age at first lambing, affecting ovine colostrum quality of dairy ewes under intensive management conditions. Moreover the Brick refractometer can be used to easily evaluate colostrum quality at ovine dairy farms.

Efficacy of a novel formulation of injectable eprinomectin against natural gastrointestinal nematode (GIN) infections in semiextensive dairy goats

Pedro Rodriguez ^{1,†} Juan P. Casas ² Julio G. Prieto ³ Manuel La Nuez ³ Joaquin Sánchez ⁴ Juan M. Nieto ⁵ Miguel A. Habela ⁵

¹Ceva Sante Animale, Libourne, France, ²Ceva Salud Animal, Barcelona, ³Biomedical Sciences Department, University of León, León, ⁴Animal Medicine Department Pathology, ⁵Animal Health Department. Parasitology, University of Extremadura. Veterinary Faculty, Cáceres, Spain

Objectives: Nematode gastrointestinal infections is an important parasitic problem in goats worldwide. Eprinomectin is the latest avermectin developed to control internal and external parasitosis in cattle. Eprinomectin has a large spectrum, high endectocide efficacy and a low excretion in milk that makes it appropriate for the use in lactating animals. A new eprinomectin injectable formulation has been developed with 0 withdrawal period in milk for dairy cattle. The objective of the present study was to evaluate the efficacy of Eprecis 20mg/ml against natural gastrointestinal nematode infections in goats.

Materials and Methods: From a 400 mixed production goats flock located in Extremadura (Spain) 30 animals were selected. The selected animals had an average milk production of 1.5l/day at the moment of treatment. All animals were naturally infected by gastrointestinal nematodes. Faecal egg counts (FEC) of GIN were performed. The arithmetic average of egg per gram of faeces (epg) excretion of the flock was ≥300. The flock wasn't treated with anthelmintics at least 2 months prior to the beginning of the trial.

Experimental design

Animals were randomly distributed in 3 groups of 10 animals each. G1 (control group/not treated), G2 (animals treated at 0.2mg/kg body weight (bw) subcutaneously), G3 (animals treated at 0.4mg/kg bw subcutaneously).

On D0 animals were treated with the dose determined and on D0, D7, D15 and D30 coprological exams (FEC) were performed (Mc Master, 1970). Coprocultures (Van Wyk, 2004) were also performed to identify the nematodes present by using morphological characteristics as described by Smith, 1981.

Results: All groups had a similar arithmetic average epg on D0 (the day of the treatment): 300 (G1), 345,4 (G2) and 320 (G3). Animals on Group1 (control) showed a continuous eggs excretion after treatment. Arithmetic average epg excretion was 400 on D7, 440 on D15 and 280 on D30.

Animals on Group2 (treated at 0.2mg/kg bw subcutaneously) showed an arithmetic average epg excretion of 0 at D7 and D15 and 54,5 epg at D30.

Animals on Group3 (treated at 0.4mg/kg bw subcutaneously) showed an arithmetic average epg excretion of 0 at D7 and D15 and 20 epg at D30. Both treated groups showed an efficacy of 100% up to D15. On Day 30 both groups had a slight rise on epg with an efficacy <85%.

Conclusions: A novel injectable formulation of eprinomectin (Eprecis 20mg/ml) has been proven to be efficacious on reducing gastrointestinal nematode populations in naturally infested goats flocks at a rate of 0.2 or 0.4 mg/kg bw both applied subcutaneously. The persistency, based on epg counts, was of at least 15 days for gastrointestinal nematode infections. Injectable eprinomectin, can therefore be considered as a new and efficacious tool in the control of nematodes infections in dairy goats.

P01-001-086

Transmission of the classical scrapie agent via goat milkTimm Konold¹, Steve A. Hawkins², Hugh A. Simmons¹, Lorenzo Gonzalez³¹Animal Sciences Unit, ²Pathology Department, Animal & Plant Health Agency Weybridge, Addlestone, ³Pathology Department, Animal & Plant Health Agency Lasswade, Penicuik, United Kingdom

Objectives: There is evidence that scrapie, a transmissible spongiform encephalopathy of sheep and goats, can be transmitted from ewe to lamb via milk. This study aimed to determine whether milk collected from goats naturally infected with classical scrapie is also able to transmit the scrapie agent.

Materials and Methods: Milk was collected from eight scrapie-infected goats at clinical or pre-clinical stage and fed to lambs with scrapie-susceptible prion protein genotype (ARQ/ARQ) from one day of age. Lambs were sourced from an established classical scrapie-free flock. The milk from each doe, which included colostrum from two goats, was fed to a pair of lambs (volume ranging from 8 to 87 litres per lamb). Pairs of lambs were kept separate and only mixed if infection was confirmed by immunohistochemical examination of a rectal biopsy. Five ARQ/ARQ sheep were kept in the same building as environmental controls and fed milk replacer. Milk recipient sheep were culled at clinical end-stage and any remaining sheep including controls culled at approximately 1850 days of age. Scrapie diagnosis was made on examination of brain and lymphoid tissues by immunohistochemistry.

Results: Six pairs of goat milk recipient sheep, which had been fed the largest volume of goat milk (38-87 litres per lamb), developed signs of scrapie and were culled at 1122-1552 days of age (mean 1362 days). Scrapie was confirmed by immunohistochemistry. The two pairs of lambs fed approximately 8 litres of milk and culled between 1492 and 1872 days of age and the five control sheep culled from 1858 days of age did not develop signs associated with scrapie, and scrapie was excluded by immunohistochemistry.

Conclusions: Milk from naturally infected goats is infectious and able to transmit the scrapie agent to sheep. Some milk recipient sheep did not show evidence of infection, which may be explained by the lower milk volume consumed, by a lower infectious titre of the milk they received, or by a hypothetical lower susceptibility of sheep to goat scrapie compared to goats.

Field trial to evaluate efficacy of a novel vaccine against biofilm formation by staphylococci, in protecting ewes against staphylococcal mastitisNatalia G. Vasileiou¹, Katerina S. Ioannidi¹, Vasia S. Mavrogianni¹, Dimitris C. Chatzopoulos¹, Dimitris A. Gougoulis¹, Stella N. Kalonaki¹, Teresa Calvo González-Valerio², Roger Guix Vallverdu², Stelios Argyros³, George Fthenakis¹¹Veterinary Faculty, University of Thessaly, Karditsa, Greece,²Laboratorios Hipra S.A., Girona, Spain, ³Laboratorios Hipra S.A., Athens, Greece

Objectives: Objective of the field trial was to evaluate the efficacy of a novel vaccine for protection of ewes against staphylococcal mastitis. The

vaccine induces antibodies against the poly-N-acetyl β -1,6 glucosamine exopolysaccharide, the main component of the extracellular biofilm matrix of staphylococci, and acts in preventing slime production and consequently biofilm formation by these organisms, which are a principal causal agent of ovine mastitis.

Materials and Methods: The trial was performed in an intensively-managed dairy sheep farm in Greece. In total, 150 ewes were enrolled in the study: 76 vaccinated (group V) and 74 unvaccinated controls (group C). The vaccine that was evaluated, is licenced in the European Union (Vimco®; Laboratorios Hipra S.A.) and contains an inactivated slime-producing, biofilm forming *Staphylococcus aureus* strain. Initial vaccination of ewes was performed 6 to 5 weeks before expected lambing date, followed by a repeat vaccination 3 weeks later. Ewes were examined initially once during the first 15 days after lambing and then at monthly intervals up to the end of a 165 day-long lactation period. At each examination, milk samples were collected for bacteriological and cytological examination, which were performed by using established techniques. Blood samples were collected before start of vaccination, as well as 3 and 21 weeks after completion of the full vaccination program from 10 ewes into each group; serum was tested for anti-staphylococcal slime antibodies by means of an ELISA assay. Staphylococcal mastitis was defined as the simultaneous isolation of staphylococci (*S. aureus* or coagulase-negative staphylococci) from a milk sample and presence of either clinical signs (clinical disease) or increased cell content in the sample (subclinical disease). Incidence of staphylococcal mastitis was calculated for the total lactation period. Risk ratios were calculated for that period, as well as for the periods 1-90 and 91-165 days post-lambing.

Results: Fewer cases of staphylococcal mastitis were recorded in group V than in group C ewes (2 versus 3 clinical and 15 versus 23 subclinical, respectively). Incidence risk of mastitis in group V was significantly smaller than in group C: 0.283 versus 0.495, respectively, throughout the trial ($P=0.004$). There was clear evidence that vaccinated ewes were at smaller risk to develop mastitis than controls: throughout the trial, there were 0.00196 cases of mastitis per day at risk of animals into group V and 0.00376 cases for animals into group C ($P=0.017$); respective figures for the first stage of the lactation period (up to 90th day post-lambing) were 0.00209 and 0.00516 ($P=0.004$) and for the second stage of the lactation period (after 90th day post-lambing) were 0.00170 and 0.00048 ($P=0.110$). Further, there was evidence that group V ewes developed mastitis later in the lactation period than the controls: on average the 83rd day versus the 33rd day post-lambing ($P<0.001$). Differences in titres of anti-staphylococcal slime antibodies between ewes in the two groups were not significant before vaccination: median values 5.11 and 3.27 for group V and group C, respectively ($P=0.49$). Differences became significant 3 weeks after completion of vaccination schedule: median values 15.67 and 1.95 for group V and group C, respectively ($P<0.001$); 21 weeks after completion of vaccination schedule differences between groups were significant: median values 5.88 and 0.38 for group V and group C, respectively ($P=0.004$), although in some vaccinated ewes titres had returned to below protective levels.

Conclusions: The results confirmed a protective effect of the vaccine against staphylococcal mastitis. This was stronger up to the 90th of the lactation period. Subsequent waning of anti-staphylococcal slime antibodies corresponded to reduced protection. Protection during the first stage of lactation is important, as at that period there is increased incidence risk of mastitis due to the post-partum reduced immunity often observed in ewes. Milk yield of ewes is highest at that stage, therefore mammary infections have a significant adverse effect both in dairy (reduced milk production) and in meat (suboptimal growth of lambs) production systems.

Comments: The work has been carried out as part of a research grant by Laboratorios Hipra S.A.. The funding organisation did not apply any influence in the experimental design or the presentation of the results of the study.

Efficacy of a novel vaccine against biofilm formation by staphylococci, in protecting ewes against experimentally induced staphylococcal mastitis

Natalia G. Vasileiou ¹Vasia S. Mavrogianni ¹Katerina S. Ioannidi ¹Dimitris C. Chatzopoulos ¹Teresa Calvo González-Valerio ²Roger Guix Vallverdu ²Stelios Argyros ³George Fthenakis ¹

¹Veterinary Faculty, University of Thessaly, Karditsa, Greece, ²Laboratorios Hipra S.A., Girona, Spain, ³Laboratorios Hipra S.A., Athens, Greece

Objectives: Objective of the experiment was to study the efficacy of a novel vaccine for protection of ewes against experimentally induced staphylococcal mastitis and to evaluate potential effects in milk yield of ewes. The vaccine induces antibodies against the poly-N-acetyl β-1,6 glucosamine exopolysaccharide, the main component of the extracellular biofilm matrix of staphylococci, and acts in preventing slime production and consequently biofilm formation by these organisms, which are a principal causal agent of ovine mastitis.

Materials and Methods: In total, 19 ewes were used in the study. They were allocated into group A (n=9; vaccination, intramammary challenge), B (n=3; vaccination, no challenge), C (n=4; no vaccination, intramammary challenge) or D (n=3; no vaccination, no challenge). In ewes into groups A or B, initial vaccination was performed 5 weeks before expected lambing date, followed by a repeat vaccination 3 weeks later; the vaccine that was evaluated, is licenced in the European Union (Vimco[®]; Laboratorios Hipra S.A.) and contains an inactivated slime-producing, biofilm forming *Staphylococcus aureus* strain. In ewes into groups A or C, intramammary challenge was carried out with 10⁶ cfu of a slime-producing *Staphylococcus chromogenes*, inoculated directly into the left mammary gland cistern. Clinical examination (results expressed on a 0-5 scale taking into account mammary and systemic signs) and milk sample collection for bacteriological and cytological examination by using established techniques were undertaken daily for 10 days after challenge day and then at weekly intervals for two months after the challenge day. Milk quantity measurements were performed the day before and at weekly intervals after the challenge day. These data referred to milk volume collected from a mammary gland of a ewe over a 4-hour period on each measurement day; comparisons of milk quantities collected were performed (i) between the two glands within the same group, (ii) between groups and (iii) between quantities collected before and after challenge day within the same group.

Results: No adverse reactions were recorded in any ewe after any vaccination. After challenge, clinical signs in vaccinated (group A) were numerically milder than in unvaccinated (group C) ewes: mean score of clinical signs was 0.34 versus 1.50 (P=0.197), respectively. Further, the experimental mastitis was resolved numerically earlier in vaccinated (group A) than in unvaccinated (group C) ewes; duration of disease was 18.7 days versus 31 days (P=0.214), respectively. Before challenge day, average (per ewe) milk quantities collected from the left (LMG) and right (RMG) mammary gland were similar within the same group (P>0.11); there was significant difference among group A and C (120 mL LMG, 128 mL RMG and 152 mL LMG, 152 mL RMG, respectively; P=0.045), but not among other groups (P>0.12). After challenge day, average (per ewe) milk quantities collected from LMG or RMG were similar within groups A, B, D groups (P>0.10), but not within group C (76 mL LMG versus 91 mL RMG; P=0.04). Furthermore, the significant differences observed among group A and C before challenge day had not been apparent after that (P=0.49), as decrease on milk quantities collected was greater in group C ewes (average milk quantity per ewe on the challenged mammary gland: 66.5 mL) compared to group A ewes

(average milk quantity per ewe on the challenged mammary gland: 40.0 mL) (P=0.035).

Conclusions: There is no documentation available regarding efficacy of this licenced vaccine against experimental intramammary challenge of ewes with staphylococci directly into the mammary parenchyma and effects on milk yield of vaccinated animals. The results confirmed the protective effect of the vaccine, as evidenced by the milder clinical signs, the earlier resolve of the disease and the smaller decrease in milk yield compared to results of challenge of unvaccinated ewes.

P01-001-089

Prevalence and ultrasonographic characteristics of lung and pleural pathologies that may affect the identification of ovine pulmonary adenocarcinoma.

Phil Scott ¹Chris Cousens ²

¹Virology Department, ²Moredun Research Institute, Penicuik, United Kingdom

Objectives: The objective of this study was to determine the prevalence and sonographic appearance of lung and pleural pathologies that may complicate the ultrasonographic diagnosis of naturally occurring ovine pulmonary adenocarcinoma (OPA) in adult sheep in the United Kingdom.

Materials and Methods: Adult sheep in four flocks (comprising 350, 500, 700 and 850 breeding ewes, respectively) in the United Kingdom were screened for ovine pulmonary adenocarcinoma (OPA) during autumn 2015 using a 6.5 MHz microconvex probe connected to a real-time, B-mode ultrasound machine. Trans-thoracic ultrasonographic examination of both sides of the chest was undertaken by the same operator (PS) at a rate of 50-80 sheep per hour. All sheep with OPA were culled from the flocks and necropsied. A retrospective analysis was also undertaken of 62 adult sheep with lung and/or pleural pathology submitted over a three years' period (2013-15) to the University of Edinburgh Veterinary School's Farm Animal Hospital (FAH).

Results: Two sheep with extensive unilateral fibrinous pleurisy were identified in the 700 ewe flock during the OPA screen; neither sheep showed signs of illness. Three sheep with fibrinous pleurisy were diagnosed ultrasonographically in 62 adult sheep presented to the FAH. Four sheep were treated with procaine penicillin daily for four weeks; three sheep responded well. A sharply-demarcated hypochoic area in the ventral margin of the lung field in three of these five sheep was considered to be consolidation rather than OPA because these lesions could no longer be imaged three (1 sheep) and six weeks (2 sheep) later. Six of 55 sheep with OPA in the flock screening study had extensive secondary abscessation of the OPA tumour affecting one side of the chest. Extensive secondary abscessation of OPA lesions identified during ultrasound examination of four of 52 sheep in the FAH study was confirmed at necropsy. Typically, in these 10 cases the dorsal margin of the lung lesions appeared as sharply-demarcated hypochoic areas with abscesses present as 2-3 cm diameter poorly defined anechoic areas containing multiple hyperechoic dots more ventrally. A diagnosis of OPA in all the secondary abscessation cases was made possible by finding smaller OPA lesions without secondary bacteria infection in the contralateral lung.

Conclusions: Lung consolidation imaged in three of six sheep with extensive fibrinous exudate could not be differentiated sonographically from OPA pathology therefore such sheep should be isolated, treated with antibiotics, then re-scanned 6 weeks later. Where ultrasound examination of the more ventral lung field identified multiple abscesses within consolidated lung tissue in 10 sheep, examination of the dorsal margin of pathology imaged the typical sharply demarcated pattern of OPA as well as finding typical OPA lesions in the contra-lateral lung.

On-farm ultrasonographic examination of the lungs of sheep in a pilot programme to control ovine pulmonary adenocarcinoma (OPA) in affected flocks

Phil Scott¹·Chris Cousens²

¹Capital Veterinary Services, Haddington, ²Moredun Research Institute, Penicuik, United Kingdom

Objectives: The objectives of this pilot study were to evaluate the sensitivity and specificity of high throughput trans-thoracic ultrasound scanning of the chest of sheep (50-80 sheep scanned per hour per veterinary surgeon) to detect OPA lesions in commercial sheep flocks. A benefit:cost analysis was undertaken after the first screening in four flocks to provide financial data for veterinary practitioners and farmers.

Materials and Methods: An initial prospective study had examined the authors' accuracy of trans-thoracic ultrasound examination using a 6.5 MHz sector ultrasound machine widely available in veterinary practice in the United Kingdom (DP50; BCF Technology) to diagnose OPA lesions >3 cm diameter in contact with the visceral pleura (Cousens and Scott, Vet. Record 2015;177:366). Handling, preparation and examination time was restricted to 5 minutes per sheep. One hundred sheep were examined; all 41 cases identified with suspect OPA lesions during trans-thoracic ultrasound examination had the diagnosis confirmed at necropsy, whilst sheep without ultrasonographic changes characteristic of OPA had no gross lesions of OPA at necropsy.

Subsequently, 50-80 sheep were scanned per hour by one veterinary surgeon or 50-100 sheep scanned per hour by two veterinary surgeons in four large commercial flocks (350-910 breeding sheep). Sheep with well-defined hypoechoic lesions measuring >1 cm with the echogenic appearance of previously confirmed OPA cases were deemed positive and culled from the flocks to expedite removal of as many potential OPA cases as possible. Necropsies of suspected OPA positive and negative cases were undertaken where possible. Local market prices for cull ewes at the time of examination were used in the benefit:cost calculation taking into sheep body condition score and liveweight. No allowance was made for projected reduced losses following lowered transmission of JSRV virus after removal of OPA-affected sheep.

Results: In flock A, one of 15 suspect OPA positive sheep was negative at necropsy; no lesions were found in the 12 predicted negative sheep. In flock B, one of 15 suspect OPA positive sheep was negative at necropsy; one of four predicted negative sheep had a 1 cm OPA lesion. No OPA cases were detected in flock C. Only 2 of 12 sheep from flock D were necropsied confirming OPA in both cases. Only 4 of the 21 OPA sheep in flock A and 3 of 26 OPA sheep in Flock B were picked out by the farm staff.

Estimated benefit:cost Flock A -£105, Flock B +£542, Flock C -£350 Flock D -£196.

Conclusions: The sensitivity and specificity of diagnosis was lower when operating a high throughput ultrasound scanning system where lesions >1 cm were considered as OPA positive. In negative and low prevalence flocks the cost of scanning was approximately 25 pence to £1 per ewe whereas in high prevalence flocks there would be an immediate financial benefit because sheep with early lesions could be sold for slaughter and furthermore did not incur disposal charges.

Modelized evolution of Schmallenberg virus seroprevalence in a sheep flock

Francois Claine¹·Laetitia Wiggers¹·Damien Coupeau¹·Benoît Muylkens¹·Nathalie Kirschvink¹

¹Integrated Veterinary Research Unit, University of Namur, Namur, Belgium

Objectives: The research sheep flock of the University of Namur was infected by Schmallenberg virus (SBV) in autumn 2011 leading to 98% (417/422) SBV seroprevalence and underwent SBV re-emergence between July and October 2012. Since then, no serological evidence of SBV novel episode has been detected increasing yearly the number of seronegative animals and probably promoting future viral re-occurrence. The objective of this study was to modelize the evolution of SBV seroprevalence in this flock by considering the duration of colostral protection in lambs and active immunity in adult sheep.

Materials and Methods: Two groups of animals were used. The group A (n=30) was composed by lambs born in 2013 from SBV infected ewes and the group B (n=50) was composed by adult sheep that encountered SBV infection in 2011 or in 2012 during viral re-emergence. Blood was collected in those two groups at different time points. In order to evaluate the decay of colostral antibodies against SBV, group A animals were collected at birth, 48h after first colostrum intake and then bimonthly until 150 days after birth (DAB). To assess the persistence of active immunity against SBV, group B animals were collected quarterly from early 2013 until late 2015. Anti-SBV antibody titers were evaluated in animals' serum by virus neutralization tests (VNT) and expressed as the dilution neutralizing 50% of the challenge virus (ED50). Animals were considered seropositive if the log² ED50 was > 3.49.

Results: In lambs, the median (min – max) length of time between birth and the first detection of VNT negative result was 122 days (74 – 144). In adult sheep having encountered SBV infection, all the 50 animals remained seropositive from early 2013 until late 2015. Median (min-max) log² ED50 anti-SBV antibody titers in early 2013 equaled 8.97 (6.48 – 10.96) and were significantly higher than titers obtained at the following sampling times that equaled 8.47 (6.47 – 8.47) in early 2014, 8.47 (6.47 – 8.47) in early 2015 and 8.47 (6.47 – 8.47) in late 2015 respectively (p<0.05). Based on these results, lambs born from SBV seropositive ewes infected by the virus in 2011 or in 2012 were considered to benefit from colostral protection until 4 months of age. Adult animals that encountered SBV infection in 2011 or in 2012 were considered seropositive from their time of infection to date. Animals born after the period of SBV re-emergence (after October 2012) were considered seronegative as their lambs were deprived of colostral protection against SBV. By considering these data, lambing periods (4/year) and the renewal in this research sheep flock, the evolution of SBV seroprevalence was modelized. In early 2013, the estimated within-flock SBV seroprevalence equaled 91% (669/735) while it equaled 76%

(509/669) and 50% (235/474) in early 2014 and late 2014 respectively. In autumn 2015, the SBV seroprevalence dropped to 37% (152/410).

Conclusions: In conclusion, based on calculated duration of colostral protection in lambs and evaluation of long-term immunity in adult sheep, the evolution of SBV seroprevalence was modeled at a herd scale. It appears that the absence of novel SBV circulation since 2012 associated with flock renewal has clearly increased the number of seronegative animals as soon as colostral protection against SBV disappears. This results in supposed high flock susceptibility to SBV infection. The accuracy of this model needs to be confirmed by VNT among the entire sheep flock.

Comments: The authors thank Christine Baricalla and Benoît Bolkaerts for their helpful technical assistance.

P01-001-092

Association of milking parlours and milking procedures with subclinical mastitis in dairy sheep

Sofia Afroditi Termatzidou¹ Sotiria Vouraki¹ Panagiota Kazana¹ Athanasios Gelasakis¹ Georgios Valergakis¹ Georgios Arsenos¹

¹Laboratory of Animal Husbandry, School of Veterinary Medicine, Faculty of Health Sciences, Aristotle University, THESSALONIKI, Greece

Objectives: The standard operating procedures of machine milking are usually underestimated or ignored by the majority of dairy sheep farmers. As a result, udder health problems and large variation in milk quality dominate the routine of dairy flocks. The objective here was to assess the role of milking parlours on udder health and particularly the prevalence of subclinical mastitis in dairy sheep.

Materials and Methods: A random number of twenty-eight dairy sheep farms, located in Northern Greece, were used. Each farm was visited by a team of two veterinarians that assessed the structure and function of the milking parlour. A designated recording form was used to assess the following: i) type and structure of the milking parlour, including dimensions and holding area, numbers of stalls and milking units, diameters of pipelines, number of milkings per day, frequency of teat cup liners replacement and general maintenance. Moreover, a specific mobile device (Exendis Milking System Analyser PTV) was used to measure the vacuum level in the clusters (in order to compare it with the vacuum of the pump), the pulsation rate and the duration of pulsation phases, in three milking units of each line in every milking parlour. A random sample of milking ewes from each flock, representing about 20% of the total population in the flock, was selected for milk sampling in order to perform California Mastitis Test (CMT; scores 0-4) as an indicator of subclinical mastitis. If the percentage of ewes with milk assigned CMT score 3 and 4 was over 20%, then the flock was considered as positive for subclinical mastitis. Data were analysed using univariate analysis of variance with SPSS 22 statistical software. Vacuum level, difference of vacuum level between clusters and vacuum pump, pulsation rate, pulsation ratio and cluster removal after vacuum cessation were transformed into categorical variables and used as fixed effects.

Results: In 71% of the flocks, the percentage of animals with CMT 3 and 4 was over 20%. The average percentage of ewes with CMT 3 and 4 was 7% and 22%, respectively. The holding area was small compared to the number of milking ewes in the majority of the flocks. Also, the length of milking stalls was < 90cm in 36% of the flocks and the width was < 35cm

in 25% of the flocks. Additionally, in 14% of farms, the diameter of pipes in the milk line was smaller than normal, which resulted in a decrease in vacuum level and acts as a predisposing factor of subclinical mastitis. At only 57% of the flocks the milking machine maintenance was done by a specialist. Furthermore, only one farmer replaced the liners after 2500 milkings; all others were well above this number. In 79% of farms the milking procedure was considered inappropriate. The effect of ewes per milking unit was statistically significant, with the flocks that had more than 11 ewes per unit showing a higher percentage of subclinical mastitis (24.5% to 31.4%, P=0.012). The vacuum level measured in clusters differed significantly from that in the vacuum pump (≥ 2 kPa) at two or more measurements in 50% of flocks and at one measurement in 21% of flocks. In case such difference existed at two or more measurements, subclinical mastitis was observed in a significantly higher percentage (33.5%) than in the other cases (24.7%, P=0.047).

Conclusions: Errors in milking process and lack of proper maintenance of the milking parlour increased the prevalence of subclinical mastitis in dairy sheep. Farmers should have the milking parlours serviced by specialists in order to limit any issues that have negative consequences on animal health and welfare.

Usefulness of clinical observations and blood chemistry values for predicting clinical outcomes when treating dairy goats with pregnancy toxemia

Julia Silveira¹ Miguel Lima²

¹Faculdade de Medicina Veterinária - Universidade de Lisboa, Lisboa, Portugal, ² Departamento de Clínica, Faculdade de Medicina Veterinária - Universidade de Lisboa, Lisboa, Portugal

Objectives: The objective of this study was to establish a prognostic algorithm for dairy goats with pregnancy toxemia (PT) based on the blood values for pH, beta-hydroxybutyric acid (BHBA), glucose, ions (K⁺, Na⁺, Cl⁻), blood gases and clinical signs.

Materials and Methods: This study was done on a 1,800-head dairy goat commercial farm. The goats were of two breeds: Alpine and Saanen. The present study involved a total of 32 goats. All the goats included in this study were dry goats.

Any pregnant doe in the dry doe group that refused to eat when fresh feed (concentrate) was offered (4 times during a 24 hour period) was considered to be a PT suspect and her blood BHBA value was determined using an electronic on-farm test (Precision Xceed®, Abbott, UK). If this value was found to be 3 mmol/L, or greater, she was considered a PT doe and handled accordingly.

At the time that each PT doe was enrolled in this study, a physical examination was performed, clinical signs (of disease) and vital signs (rectal temperature, heart rate, respiratory rate and ruminal motility) were determined and recorded. In addition, a blood sample was obtained from the jugular vein with a 20-gauge needle using a 1 mL new syringe and the following parameters ions (Na⁺, K⁺, Cl⁻ and HCO₃⁻), glucose, pH, BE (Base Excess), pCO₂ and BUN were measured on the farm, using a portable analyzer (i-Stat®, Sensor Devices Incorporated, Waukesha, WI; USA):

Consent was obtained from the owner of the animals prior to their enrollment in the study. All the experimental procedures (handling, blood sampling, and caesarean when applicable) were performed so as to

minimize the stress and discomfort experienced by the animals.

Results: Polypnea (88%), swollen limbs (78%), anorexia (69%), recumbency (66%), neurological signs such as "star gazing" or opisthotonus (9%) and drooped ears (9%) were the most observed clinical manifestations in the 32 PT goats. In the present study, the case fatality rate was 75% (24/32).

Nineteen out of 21 recumbent goats died. Sixteen out of 17 goats with anorexia died. All the goats that showed neurologic signs (3 out of 3) and drooped ears (3 out of 3) died. Mean BHBA and glucose values in the goats that died were not significantly different from those in goats that survived (6.5 vs 6.0 mmol/L and 2.2 vs 2.0 mmol/L, respectively). The blood values for pH (7.13 vs 7.30), pCO₂ (26 vs 33 mmHg), HCO₃⁻ (8 vs 21 mmol/L), BE (-20 vs -5 mmol/L) and K⁺ (2.7 vs 3.7 mmol/L) were significantly lower in the goats that died.

Conclusions: The results showed that anorexia, recumbency, neurological signs and drooped ears can be used as prognostic indexes in goats with PT. Among the blood parameters to be considered, K⁺ and those indicative of a metabolic acidosis can also be used as prognostic indexes. The other blood parameters measured in this study (Na⁺, Cl⁻, glucose, BUN and BHBA) do not have prognostic value in goats with PT.

Case study on the usage of Gamithromycin for the treatment and prevention of ovine caseous lymphadenitis (*Corynebacterium pseudotuberculosis*).

Rawi Taoufik¹EMBARKI Tarik¹Homer David²Lazare Tano²Omari Tadlaoui Khalid¹

¹MCI Santé Animale, Mohammedia, Morocco, ²Merial, Lyon, France

Objectives: Caseous lymphadenitis (CLA) is an infectious disease caused by *Corynebacterium pseudotuberculosis*. The objectives of this case study were to assess if a single injection of Gamithromycin (GAM) subcutaneously could improve the recovery process and case management associated with the more common and less severe CLA cases seen in a Moroccan 1000+ sheep feed-lot where routinely 40 to 60% of the animals are affected with CLA and, if so, to assess the potential for GAM to be used to reduce the prevalence of the disease in the flock.

Materials and Methods: Individual animals affected with CLA, in Morocco, are treated as required with either antibiotics and/or surgical draining and flushing of the abscesses. This approach is intensive and many treated cases suffer protracted periods of recovery. Further, the wounds can also be a source for on-going infection of the flock. In 2013, thirty sheep of different ages (average weight of 60 kg) were included in the study on the basis of having a detectable and non-ruptured small to medium sized abscess on D0 and on not having received any prior antibiotics to treat the condition. All sheep were injected subcutaneously on day 0 with Gamithromycin (Zactran®) using a consistent dose of 4 mL (10 mg/kg). The pharmacokinetics of Gamithromycin make it potentially ideal for managing CLA cases, with a tendency to concentrate for persistent periods in inflamed tissues. Each animal was then closely monitored over a 30-day period post-treatment. The information collected for each case at each time point were: Lymph node affected, Size of swelling at D0 (Small, Medium, Large, or Very Large), Degree of change in swelling on days 5, 15 and 30 (0 = no improvement to 5 = resolved) and detection of abscess rupture. This type of monitoring allowed for

at least a semi-quantitative determination of the level of improvement for each case and also for an assessment of the speed of response. Towards the end of 2014, the entire flock was treated at the same time with a single dose (6 mg/kg) of GAM.

Results: All 30 cases had small to medium-sized abscesses in either the parotid (12) or retropharyngeal (18) regions. Six sheep also had large to very large abscesses in either the breast/chest region (1), the groin/inner thigh region (2) or the gluteal/perineal region (3). All assessed abscesses showed significant reduction in size by day 30 (with no rupture) and were noted as improving in size from the first post-treatment visit (day 5). All swellings were still detectable on day 30 but the vast majority were graded as 4 (the last grade prior to complete resolution). Whilst culturing abscess material was not part of the study, *C.pseudotuberculosis* has been routinely isolated from affected sheep on this farm, including one of the included cases that was sampled during this study. In 2015, following the whole flock treatment in 2014, there were 20 abscess cases identified (2-5%).

Conclusions: On this farm, all small to medium-sized lesions showed significant improvement without rupturing or requiring surgical intervention, virtually resolving by the end of the study period. The response to the whole flock treatment was also impressive with a dramatic reduction in flock incidence being seen in the following year. The results seen were positive and support further studies to both confirm these findings and to better define both the type of cases suitable (e.g. site and severity) and the dosing regimen(s) required. The recommended label dose for cattle is 6 mg/kg.

Comments: Zactran is a registered trademark of Merial Inc.

Ovine Herpesvirus 2 In Goats In Austria: Epidemiological And Case Study

Reinhild Krametter Froetscher¹Andrea Klang²Karin Möstl³Gabriela Bagrinovschi³Angelika Iglseider³

¹University Clinic for Ruminants University of Veterinary Medicine Austria, ²Institute of Pathology and Forensic veterinary Medicine, ³Institute of Virology, 1210 Vienna, Austria

Objectives: Ovine herpesvirus 2 (OvHV-2) belongs to the genus Macavirus, in the subfamily Gammaherpesvirinae. OvHV-2 is worldwide endemic, mainly in sheep but also in goats. It is well adapted to these species and does not induce any clinical signs. In clinically susceptible hosts, such as cattle, bison, deer and buffalo an OvHV-2 infection causes Malignant catarrhal fever (MCF), a disease that usually has a fatal outcome (Russell et al., 2009).

Materials and Methods:

Epidemiological study

The study was carried out among 100 goats, being patients of the University Clinic for Ruminants of the University of Veterinary Medicine Vienna. Blood samples collected from the animals were investigated for OvHV-2 specific DNA using PCR.

Case study

A female dwarf goat with a five week history of alopecia and crusting dermatitis admitted to the Veterinary University Clinic for Ruminants. Moreover, 12 contact sheep and two contact goats. All animals were clinically examined and blood samples as well as conjunctival and nasal

swabs were collected and investigated for OvHV-2 specific DNA using PCR.

Results:

Epidemiological study

OvHV-2 specific DNA was detected in 7 (7%) blood samples. The 7 animals (6 female, one male) were between 1 and 14 years old. Clinical signs typically for MCF were not seen in these animals.

Case study

The goat described was the only affected animal in a flock harbouring 12 sheep and 2 goats. At admission clinical examination revealed that the goat was mildly depressed and dehydrated with an increased body temperature and heart rate. Conjunctivitis, photophobia, keratitis and anterior uveitis were diagnosed in both eyes. The hair coat was generally dull and rough with hairless areas. Patches of the skin were hard, dry, hyperkeratotic, painful and locally fissures and ulcerations were seen. After 12 days of hospitalisation the goat developed nervous signs and was euthanized. Pathology, histopathology and virological investigations confirmed the suspected diagnosis OvHV-2 infection.

The remaining animals of the flock were clinically healthy. In blood samples of eight sheep and one contact goat OvHV-2 specific nucleic acids were found. Moreover investigations of conjunctival /nasal swabs showed in one sheep a positive result. Sequence analysis performed on OvHV-2 positive samples showed a 100%identity between those from the animals of the flock and that one of the clinically affected goat (Bagrinovschi et al., 2014).

Conclusions: Only a few epidemiological studies according the dissemination of OvHV-2 in goats are described worldwide. Among the animals investigated in the study presented here the infection rate with OvHV-2 was 7%. To determine the importance of goats in the spread of OvHV-2 among ruminants in Austria further studies are needed. However, clinical signs in goats affected with OvHV-2 reported here are rarely described in the literature. This was the first case of an OvHV-2 infection in a goat in Austria characterised by clinical signs.

Determination of risk factors associated with postparturient udder edema in dairy goats

Muhammad Avais¹·Muhammad Atif²Jawaria A. Khan²Muti U. Rehman³Muhammad Haisem U. Rasool²

¹Department of Clinical Medicine and Surgery, University of Veterinary and Animal Sciences, Lahore, Pakistan, ²Department of Clinical Medicine and Surgery, University of Veterinary and Animal Sciences, Lahore, Pakistan, ³Department of Pathology, University of Veterinary and Animal Sciences, Lahore, Pakistan, Lahore, Pakistan

Objectives: Udder edema is one of the major problems in dairy goats imposing colossal economic losses to the farming community by affecting milk production particularly in heavy milker goats. The objective of the present study was to determine the risk factors associated with postparturient udder edema in dairy goats at different farms in Lahore, Pakistan.

Materials and Methods: A prospective study was carried out in which the data was evaluated to determine risk factors associated with udder edema in dairy goats. Three hundred and fifty (n=350) dairy goats either pregnant, near to parturition or recently parturited were considered

for this study. Udder edema was diagnosed on the basis of visible and palpable changes in the udder tissue. Goats with enlargement of udder with evident skin distension, fluid accumulation and retention of finger imprint were considered as case of udder edema. Time to return to normal of fingerprint of the skin of the udder for more than 3 sec confirmed the diagnosis. Variables considered as potential risk factors were breed, age at kidding, kidding month, doe weight, height at the level of shoulders, body condition score at kidding, kidding difficulty, retention of placenta, number of gestation, previous history of udder edema, number of off-springs, gender of off-springs, milk yield, housing system, feeding system and type of feeding. Each of the factors included were evaluated by Chi square test. Adjusted odds ratios (OR) and 95% confidence intervals (95% CI) was reported.

Results: Goats fed on more salt than recommended during pregnancy were 18.08 (OR) times more likely to develop udder edema than goats not fed to salt. Goats giving birth to male kid are at greater risk. Recently parturited goats (1-2 day) were 1.18 times more susceptible to udder edema compared to goats 3-5 days after kidding. On the other hand, goats that were pregnant >4.5 m (near to parturition) were 0.43 times more prone to udder edema than goats of <4 m pregnancy. Younger goats were 1.263 times more likely to develop udder edema than older ones (P>0.05). The goats in first Parity were 1.26 times more likely to develop udder edema than goats in 2nd parity and so on. Occurrence of udder edema was 1.54 times higher in goats kidding during the month of January compared to November-December and February-March. Goats having kidding difficulty (dystokia) were 3.60 times more likely to contract udder edema than goats having normal kidding (P<0.05). Goats with retained fetal membranes were 2.27 times more prone to udder edema than without RFM. Goats having previous history of udder edema were 3.26 times more susceptible to develop udder edema than goats which did not develop udder edema previously (p<0.05). It was found that as the number of the off-spring increased chances of udder edema were also increased. Results showed that if there were twins then chances of udder edema are increased by 0.65 times. It is also statistically significant when compared a single kid with twins (P<0.05) but it is statistically non-significant when twins and triplets were compared (P>0.05).

Conclusions: It was concluded that several risk factors like high salt concentration in feed, age of the goats, parity, retained fetal membranes, number of kids at birth and sex of the kid are significantly associated with udder edema in dairy goats.

Comments: This paper represents novel information about risk factors of udder edema in dairy goats and is first ever study in Pakistan.

Environmental and management influences on Haemonchus contortus prevalence on North Carolina goat farms

Derek Foster¹·Hannah Sylvester¹Emily Griffith²Megan Jacob¹

¹Population Health and Pathobiology, NC State University College of Veterinary Medicine, ²Statistics, NC State University, Raleigh, United States

Objectives: The objective of this study was to identify factors contributing to H. contortus presence on North Carolina goat farms, and identify parasite reduction strategies that are effective in controlling H. contortus infection.

Materials and Methods: Fecal samples were collected from 560 adult goats from 51 different farms. Goat farms were identified from hospital, producer group, and North Carolina Department of Agriculture records. Farms were solicited by postal mailings, and participating farms were visited to collect fecal samples and administer a survey designed to assess potential risk factors. A McMaster's exam was performed on each fecal sample to determine fecal egg count (FEC). A second survey was administered to elicit more quantifiable data after analysis of initial survey.

Results: Univariate analysis revealed farm-type, herd size, anthelmintic use, pasture type, presence of a natural water source, raised feeding trough use, and owner perception of difficulty controlling parasitism to be significantly associated with average farm FEC. Age, grazing environment, pasture grass height, herd introductions, breed, goat use, kidding, lactation, diet, and coccidia prevalence were significant in predicting individual goat FEC. Multivariate analysis revealed breed, goat use, anthelmintic dosing strategy, daily dietary protein intake, Coccidia presence, age, kidding and lactation, and dew exposure to be significant in predicting FEC.

Conclusions: Results identified young age, recent kidding, and lactation as risk factors predisposing goats to *H. contortus* infection, while being a companion animal appeared to have a protective effect. Farms who never use chemical anthelmintics have the lowest FECs suggesting that alternative parasite control measures may be effective, and that preventative measures including grazing wooded areas may reduce the need for anthelmintics, and subsequently slow the development of anthelmintic resistance.

Survey on "Abscess syndrome" in small ruminants in Emilia Romagna Region (Italy)

Angelo Peli¹, Alessandra Scagliarini¹, Giovanni Casà¹, Giuseppe Merialdi², Gianluca Ferlazzo¹

¹Department of Veterinary Medical Sciences, University of Bologna,

²Istituto Zooprofilattico Sperimentale della Lombardia e dell'Emilia Romagna, Bologna, Italy

Objectives: The presence of abscesses is a widespread problem in sheep and goat, and *Staphylococcus aureus* subsp. *anaerobius* (SAAN), agent and *Corynebacterium pseudotuberculosis* (CPS), are the recognized agents of "Abscess disease", also known as Morel's disease (MD), and of caseous lymphadenitis (CLA) respectively. The objectives of this study were to evaluate clinical appearance and spread of these diseases in farms of Emilia Romagna Region and to characterize the aetiology of the clinical cases observed.

Materials and Methods: In this seven-month study, 10 farms who referred abscess presence were visited, including eight dairy goat farms which held Chamois colored goats and two sheep farms which held Sarda (milk) and Suffolk (meat) sheeps, with the average age of 7 years. Sixteen animals (14 goats and 2 sheeps) with abscessual lesions were examined and pus samples were collected by 5-10 ml syringes with 18-gauge needle, then sent for bacteriological investigations to Istituto Zooprofilattico Sperimentale della Lombardia e dell'Emilia-Romagna, Bologna department. Every sample was concurrently subjected to a bacteriological examination by direct smear on Blood Agar plates and enriched in a liquid medium Brain Heart Infusion (BHI); for every sample a Blood Agar plate was incubated at 37°C in an aerobic atmosphere and

one in an anaerobic atmosphere using a commercial kit (GENbag anaer, Biomerieux). Blood Agar plates were observed daily for a maximum period of 72 hours, then developed grown colonies were identified by fenotypic evaluations (colonial appearance, hemolysis, gram staining, urease/catalase/coagulase and other biochemical tests).

Results: Clinical examination revealed the presence of round to oval lesions, singles and rarely multiple, with smooth and uniform surface, not warm nor painful, larger ones located usually in the neck and sternal regions. The abscessual lesions were mostly located in prescapular and subauricular regions as well in head and precrucial region, neck and sternal region, ischiatic region and their size ranged between 1,5-10 cm. Animals overall body condition score was rated 2/5, probably due to CAEV presence in farms. The bacteriological examination revealed the presence of the typical agents causing abscesses like SAAN and CPS but, surprisingly, in 48% of collected samples, other bacteria was isolated like *Trueperella pyogenes*, *Staphylococcus aureus*, *Kocuria kristinae*, *Staphylococcus caprae*, *Streptococcus thoralthensis*, *Prevotella*, *Peptoniphilus asaccharolyticus*. Only in 5 cases we found a mixed infection. Some of these last species didn't previously described as cause of abscess disease in small ruminants in Italy. Furthermore it is worthwhile to note that these "non conventional" bacteria are commonly isolated in humans.

Conclusions: The results show heterogeneity of bacteria that can cause abscesses and this must be considered in the preparation of field vaccines. The key points are biosecurity measures and farm management: care of animals with abscesses to prevent spontaneous breakage and contamination of environment and livestock facilities; strong plans against flies to limit the spread of bacteria. Since we found a high prevalence of abscess caused by non conventional species of bacteria, we propose the labeling of "Abscess Syndrome" to distinguish them from the classical form know as Abscess disease and CLA.

Malignant Catarrhal Fever In Farmed Cervids In Texas

Terry Hensley^{1,2,*}

¹Texas A&M AgriLife Extension Service, ²Texas A&M Veterinary Medical Diagnostic Laboratory, College Station, United States

Objectives: Malignant catarrhal fever (MCF) is a member of the gammaherpesvirus group that contains several pathogenic viruses that affect a number of susceptible ruminant species. Malignant catarrhal fever has been reported in at least 14 species cervids. Cases from the Texas A&M Veterinary Medical Diagnostic Laboratory (TVMDL) involving MCF in cervids were reviewed to determine common clinical signs, gross and microscopic lesions, and association with known MCF reservoir ruminant species in order to assist with management of cervids and other exotic ruminants.

Materials and Methods: Cases involving the diagnosis of MCF in cervid species was reviewed to determine common clinical signs, gross and microscopic lesions, and real time PCR results. Gross lesions were recorded for necropsies performed at TVMDL. Tissues were collected from all major organs and half were fixed in 10% buffered formalin and half were saved as fresh for further testing if needed. Fixed samples were processed following standard procedures for histopathology. Samples for realtime polymerase chain reaction (qPCR) testing for MCF were prepared following accepted molecular techniques. Clinical signs were recorded as submitted by the referring veterinarian. Case which were

qPCR positive for MCF were analyzed to establish if common clinical signs, gross and microscopic lesions, and exposure to MCF reservoir species existed.

Results: During the two-year period of 2014-2015 MCF was diagnosed at TVMDL in 5 white-tailed deer and 2 axis deer from game ranches in Texas. Clinical signs ranged from listlessness, anorexia and progressive decline over three week period leading to neurological disease and death. Other affected deer showed signs of acute neurological disease. Other deer showed a more protracted disease which lasted several days before terminating in death. Gross lesions included organ enlargement, epicardial petechia, lymphadenopathy and serosal hemorrhages. The microscopic lesions included peri-arteritis and arteritis, necrotizing endarteritis, lymphoid hyperplasia and lymphocytic/mononuclear inflammation of various organs. Two MCF viruses were confirmed by qPCR; these viruses were ovine herpesvirus-2 and MCFV-Ibex.

Conclusions: Deer affected with malignant catarrhal fever can exhibit various signs which can be acute in onset. The clinical signs and gross lesions can be confused with other disease conditions affecting cervids. Definitive diagnosis of MCF must be by histopathology and/or qPCR. Susceptible cervid species are at risk of contracting MCF when pastured with or adjacent to ruminant species that are known reservoirs for the MCF virus.

Strategic control of sheep gastrointestinal nematodes using *Duddingtonia flagrans* and Levamisole Hydrochloride 5%

VINÍCIUS L. R. VILELA¹JOSÉ G. G. LINS²THAIS F. FEITOSA²FABIO R. BRAGA³JACKSON V. ARAÚJO³GABRIELA L. L. SILVA⁴SAMUEL C. LUCENA⁴VANESSA D. VIEIRA⁴ANA C. R. ATHAYDE⁴

¹Veterinary Medicine, Instituto Federal Da Paraíba, Ifpb, ²Veterinary Medicine, Instituto Federal Da Paraíba, Ifpb, Sousa, ³Veterinary Medicine, Universidade Federal De Viçosa, Viçosa, ⁴Veterinary Medicine, Universidade Federal De Campina Grande, Patos, Brazil

Objectives: The objective was to evaluate the action of *D. flagrans* pellets associated with strategic anthelmintic treatment with Levamisole Hydrochloride 5% in the control of sheep gastrointestinal nematodiosis in the Brazilian semiarid.

Materials and Methods: Were used 18 Dorper sheep, females, aged between 24-36 months and a mean weight of 50 kg. It was created three groups consisting of six sheep. In group 1, each animal received 3g of the pellets (0.6g of *D. flagrans* mycelium) for each 10 kg of body weight, twice a week for six months and a deworming with Levamisole Hydrochloride 5% each EPG \geq 1500 (Fungi + Chemical). In group 2, each animal received a dosage of levamisole hydrochloride with a 5% when EPG \geq 1,500 (Chemical); and group 3, each animal received 3g of pellets without fungi for each 10 kg of body weight, twice a week for six months, serving as Control group. The animals were weighed and it was made EPG, larval cultures, PCV and in the animals every 15 days. Monthly, samples of grass from each paddock were collected for quantification of L3/ kg D. M.

Results: The groups EPG mean began to statistically differ from day 30 (p<0.05). At day 180, the EPG mean of Fungus + Chemical group was 480, Chemical group was 1320 and Control group was 2340. The Fungus + Chemical group required less deworming with Levamisole

Hydrochloride 5% when OPG \geq 1500 (p<0.05), only eight, while Chemical group required 17. *Haemonchus* sp. was the most prevalent helminth gender in all larval culture. The Fungus + Chemical group showed superiority in PCV values throughout the experiment (p<0.05). There was a significant reduction (p< 0.05) in the recovery of L3 on pasture on the Fungus + Chemical paddock from day 30, peaking at day 180 with an average of 800 L3/ kg D.M.

Conclusions: In conclusion, the use of pellets of *D. flagrans* associated with strategic anthelmintic treatment with Levamisole Hydrochloride 5% was effective in controlling gastrointestinal nematodiosis of sheep kept in irrigated pasture in the Brazilian semiarid region.

Comments: Keywords: integrated control, nematophagous fungi, *Haemonchus* sp., farming sheep.

Assessing the effect of a reduced mulesing wound size on breech strike risk parameters and wound healing in Merino weaners

Sabrina Lomax¹Emily Sears¹

¹Faculty of Veterinary Science, The University of Sydney, Sydney, Australia

Objectives: The Code of Practice for the Welfare of Sheep states that mulesing should be performed with the minimum number of cuts suitable to the individual for flystrike protection. With the move towards a plainer bodied flock, assessment of the necessity for the current modified 'V' standard mules is required. The objective of the current study was to compare the effect of a smaller, conservative mules to the modified 'V' standard mules on wound healing and breech strike risk parameters. The outcomes of this study will also provide a scientific basis to refine industry best standards.

Materials and Methods: Two separate trials were performed on Merino ewe weaners (6-8months) in the Southern Tablelands of NSW, Australia. Animals were randomly assigned to one of two treatment groups; industry standard modified 'V' mules (MOD, 6-8 cuts) (n=100) and the conservative (CONS, 4 cuts) (n=100). In both trials, sheep were weighed and scored for key breech strike risk parameters (breech wrinkle, BRWR and perineal bare area or breech cover, BCOV) prior to and following mulesing treatment. Wounds were photographed at Day 0 and Day 28 relative to mulesing and analysed using digital planimetric software (PictZar) to obtain measurements of wound surface area (WSA, cm²), WSA to body surface area ratio (WSA:BSA) and contraction rates as an indication of healing. Tissue removed during mulesing was weighed (g).

Results: There was a significant treatment x farm interaction for weight of tissue removed (P = 0.018). The mean weight of tissue removed for the CONS treatment was significantly smaller than the MOD at both Farm 1 (85.14 \pm 1.72 g vs 113.73 \pm 1.72 g) and Farm 2 (46.17 \pm 1.73 g vs 66.54 \pm 1.75 g). There was a significant treatment x time interaction for WSA (P < 0.001). The MOD treatment resulted in a larger WSA than CONS on both Day 0 and Day 28. There was a significant reduction in WSA from Day 0 to Day 28 for both CONS (87.62 \pm 1.25 cm² vs 17.25 \pm 1.25 cm²) and MOD (150.82 \pm 1.25 cm² vs 29.53 \pm 1.26 cm²) treatments. Both treatments resulted in an 80% reduction in WSA over the 28 days. There was a significant interaction of time x treatment for BRWR (P < 0.001). Both the CONS and MOD treatments resulted in a significant reduction in BRWR (- 0.57 vs - 0.92) and BCOV (- 1.67

vs - 2.11) ($P < 0.001$). MOD treatment had significantly lower BRWR and BCOV scores than the CONS treatment ($P < 0.001$) on both farms.

Conclusions: The findings from this study provide new information and are supportive of the use of the conservative mules over a range of flock phenotypes. A conservative mulesing wound results in less mulesing cuts, less tissue removed and faster wound healing, presenting a welfare benefit to sheep undergoing the procedure. Furthermore, this method still resulted in significant improvement in breech strike risk parameters, albeit not to the same degree as the MOD method. Follow up of these sheep in flystrike seasons is important to validate the protection provided by the CONS vs MOD mulesing methods.

P01-001-102

Study Of Genetic Resources: Morphological Characteristics And Goats Morphostructural Native Community Of Cebadillas False Pen, Maravatío Michoacan

Rodolfo Lucio Dominguez ¹ Jose Luis C. Bedolla cedeño ¹ Victor M. Sanchez Parra ¹ Valente Velazquez Ordoñez ² Leticia Sesento Garcia ¹

¹Animal Production, Faculty of Veterinary Medicine and Animal Science of the University Michoacana of San Nicholas of Hidalgo, MORELIA, MICHOACAN., ²Animal Production, Faculty of Veterinary Medicine and Animal Science of the University Autonomous of State of Mexico, Toluca, Mexico, Mexico

Objectives: The objective of this work was to study phenotypically (morphology and morfoestructuralmente) native goats (Creole) located in Town of Cebadillas Corral Falso is located in the Municipality of Maravatío in the State of Michoacán de Ocampo. Cebadillas Corral Falso is 2320 meters above sea level

Materials and Methods: 110 adult animals (60 females and 50 males) from 12 deferent production units were selected and determined (by visual assessment) morphological variants TO Ears size (small, medium and large) to your ears, DO (upright, horizontal or falls), consistency of the ears, CO (rigid or pending), type of udder, TU (globosa, baggy or palillera), e-nipples, DP (parallel or divergent); and morfo-structural variables head width (ACF), head length (LCF); face length (LR), height at the withers (ACR), thoracic perimeter (PT), longitudinal diameter (DL), dorsoesternal diameter (DD), distance between horns (DC), rump length (LG), width rump (AG), width between legs (AEA), height at moths (AP) and perimeter cane (PC). For morfo-structural determinations inextensible tape measure from 1 to 150 cm and 1 cm capacity precision used to measure perimeters they were used.

Results: Morphologically it shows that there is a predominance of large ears (38.3 p.100 p.100 in females and 44 males). In relation to the direction and consistency of the ears, floppy ears males and females as well, mainly pendulous in males and females predominate pendulum. The main way the udder is globosa (53.3 p.100) although there are baggy udders (28.3 p.100) and palilleiras (18.3 p.100), forms which in turn influence the direction of the nipples (56.6 p .100 43.3 parallel and divergent p.100). The evidence for sex differences reveal a marked sexual dimorphism for morfo-structural, especially with regard to the formation of appeal of the cross, cane perimeter, thoracic perimeter and longitudinal diameter characters. Morpho-structurally no significant differences between sexes

Conclusions: Regarding the morphological characters Creole goats

has large ears, fallen and tilting consistency in both males and females. In this case the sexual dimorphism is mainly determined by the shape of the croup, the height at the withers, the width of the head and around the perimeter of cane.

P01-001-103

Effect of feeding silages from plant raw materials on the profile of fatty acids, cholesterol, and vitamins A and E in lamb meat

Przemyslaw Sobiech ¹ Stanislaw Milewski ¹ Cezary Purwin ¹

¹University of Warmia-Mazury, Olsztyn, Poland

Objectives: The type of silage given to animals may influence the quality of their end products. Inclusion of red clover into the lambs' diet in the form of both green forage and silage had a beneficial effect on the fatty acid profile in intramuscular fat because it increased the contribution of polyunsaturated fatty acids (PUFA). Feeding lambs with different silages induced changes in fatty acids metabolism in the rumen that may derive from differences in the extent of PUFAs biohydrogenation. The aim of the study was to compare selected traits characterizing the health quality of meat lambs fed silages produced from red clover, alfalfa and grass.

Materials and Methods: The experimental materials were 24 single ram lambs of the Polish Longwool Sheep variety Kamieniecka weaned at the age of 70 days. There were divided into 3 equal groups that were fed ad libitum experimental silages prepared from the second cut of red clover (RC), alfalfa (ALF) and grass (GR). The initial mean body weights of lambs were comparable in all groups: RC – 22.63kg, ALF – 22.42kg, GR- 22.71kg. The specific fattening period spanned for 60 days. All animals were placed in metabolic cages, and were fed only experimental silages ad libitum. Silage samples (1.0kg) were collected once before experiment and 3 times during the experiment. In the samples of silage the fatty acid composition was determined using Gas Chromatography. The ram lambs were slaughtered at the following mean body weights in groups: RC-33.66kg, ALF-34.69kg, GR- 31.75kg. Samples for meat analysis (100g) were collected from the musculus longissimus lumborum. In the meat following parameters were determined: cholesterol content (enzymatic method), vitamin A and E levels (high – performance liquid chromatography – HPLC method). Additionally the intramuscular fat content was determined by the Soxhlet method. The results were processed by one-way ANOVA test, and the significance of differences between groups was verified with Duncan's test using Statistica 9.0 software.

Results: The analyzed silages did not differ significantly in the content of saturated fatty acids. The silage from alfalfa was characterized by the lowest content of monounsaturated fatty acids (C18:1 – oleic and C14:1 – myristic) and the highest content of PUFA acids. The lowest content of PUFA acids was observed in the grass silage. The highest content of vitamin E in lamb meat was observed in the group fed grass silage. The highest content of fat was assayed in the meat of RC lambs (fed the silage from red clover).

The intramuscular fat of the lambs fed the grass silage was characterized by the highest contribution of C12:0 (lauric) and C14:0 (myristic) acids and the lowest content of C18:0 (stearic) acid. In the same group of lambs the highest content of C14:1 (myristoleic) acid and the lowest content of C18:3 (alpha-linolenic) and C20:2 (eicosanoic) acids were observed. The content of C18:3 and C20:2 acids was the highest in the fat of RC lambs.

Conclusions: The analysis of traits characterizing the health quality of lamb meat points to different effect of the silages administered to lambs in the fattening period. The silage from red clover was found to enhance intramuscular fat deposition in ram lambs, especially when compared to the silage from grass. The results of our study indicate that the species of plants used to prepare silage exerts a significant effect on the quality of silage and its intake by lambs. As consequence, it determines nutrient absorption and health-promoting properties of lamb meat.

P01-001-104

Coadministration of nematophagous fungi in the biological control of sheep gastrointestinal nematodes in Northeastern Brazil

Vinicius L. R. Vilela¹ Jose G. G. Lins¹ Thais F. Feitosa¹ Fábio R. Braga² Jackson V. D. Araújo² Antonielson Santos³ Dayana F. Morais³ Diego V. O. Souto³ Ana C. R. Athayde³

¹Veterinary Medicine, Instituto Federal Da Paraíba, Sousa, ²Veterinary Medicine, Universidade Federal De Viçosa, Viçosa, ³Veterinary Medicine, Universidade Federal De Campina Grande, Patos, Brazil

Objectives: It was aimed to evaluate the coadministration of fungi *D. flagrans* and *M. thaumasium* in sodium alginate matrix on gastrointestinal nematodes of lambs and adults sheep in the semiarid region of Northeastern Brazil.

Materials and Methods: An area of 1 ha (approximately 2,5 English acres) was divided into two paddocks and two experimental groups (one in each paddock) were placed on these places. Also, each group was composed by six adult females and ten young males, providing two experimental groups (Fungus and Control group). In each group, two subgroups have been created in accordance with the animal type (Adult and Young). In Fungi group, each animal received, in the feed, 3g of the pellets (0.6 g of fungal mycelium, with 0.3g of *D. flagrans* and 0.3g of *M. thaumasium*), for each 10 kg of body weight, twice a week, for six months. In Control group, each animal received, in the feed, 3g of pellets without fungus, also for each 10 kg of body weight, twice a week, during six months.

Results: It was observed a reduction of 76 % in the Eggs per gram (EPG) of subgroup Fungi - Adults and a percentage of 83 % in the subgroup Fungi - Young, when compared to their respective Control subgroups. The groups that received these fungi needed less salvage deworming, and they presented the best PCV percentages in the days 150 and 180 ($p < 0.05$). In addition, they had the best weight gain (18.7 kg) and a significant reduction of 91.6% in the number of L3/ kg D.M. in its paddock, when compared to Control groups.

Conclusions: Finally, it is concluded that *D. flagrans* and *M. thaumasium* coadministration was effective in the control of gastrointestinal nematodes of adults and young sheep in the semiarid region of Northeastern Brazil.

Keywords: *Duddingtonia flagrans*, nematophagous fungi, *Monacrosporium thaumasium*, sheep farming

Glutamate Precision Supplementation, Antral Follicular Development And The Secretion Pattern Of Lh In Adult Goats.

C.A. Meza-Herrera¹ C.E. Santamaria-Estrada¹ G. Calderon-Leyva² C.A. Rosales-Nieto³ F.G. Veliz-Deras² C.A. Romero-Rodriguez¹ C. Navarrete-Molina¹ B. Ramírez-Omaña¹ B.S. Girón-Gómez¹ A.R. Alvarez-Ruiz¹

¹URUZA, Universidad Autónoma Chapingo, Bermejillo, Dgo., ²Programa de Posgrado, UAAAN-UL, Torreón, Coahuila, ³CE-SLP, INIFAP, San Luis Potosí, SLP., Mexico

Objectives: Nutritional supplementation, even without detectable increases in live weight, the “acute effect of nutrition”, can increase reproductive outcomes. The physiological signals involved are not fully elucidated, but activation of glutamatergic neurons should be implicated. Glutamate is a primary mediator of excitatory synaptic transmission in the CNS and has receptors localized in a variety of hypothalamic nuclei, some of which are critical for reproductive function. We aimed to evaluate the possible effect of acute-short term glutamate supplementation upon antral follicular development and the serum levels, pulsatility and AUC of LH in goats.

Materials and Methods: The experiment was carried-out at the Southern Goat Research Unit, UACH-URUZA, Mexico (25°NL, 1,117m) under decreased photoperiods (Nov). Adult goats (n=22) 7/8 Sannen-Alpine were randomly distributed to individual pens and divided into two experimental groups, with homogeneous live weight (LW) and body condition (BC): 1) Glutamate group (GLUT, n=10, LW=45.8±4.37 kg; 0.175 mg kg⁻¹ LW of glutamate, i.v. applied on days 1, 9, 14 and 17 post-ovulation and 2) Control group (CONT, n=12, LW=46.2±5.87 kg; received saline (0.0875 mL kg⁻¹ LW, i.v.). The basal diet considered alfalfa hay (14% CP; 1.14 Mcal kg⁻¹ mNE) and corn silage (8.1% CP; 1.62 Mcal kg⁻¹ mNE). After 2-wk adaptation period to general management and conditions, the estrous cycles were synchronized with the use of intravaginal sponges; glutamate was applied on days coincident to the emergence of the four follicular waves. The population of antral follicles (> 5 mm) was estimated on d19 (the mid-follicular phase) throughout transrectal ultrasonographic scanning (TUSS) with a 7.5 MHz linear-array transducer (Toshiba Medical Systems, Ltd, Crawley, UK) and an intensive blood sampling (6 h x 15 min) was performed the last TUSS to evaluate serum LH through RIA. Data were analyzed by a CRD-ANOVA, while separation of the means was assessed using the LSMEANS-PDIFF option of the PROC GLM. All statistical analyses considered the procedures of SAS (SAS Inst. Inc. V9.1 Cary, NC, USA). Correlation analyses between different response variables were conducted by Pearson’s product-moment test; least-square means ± SEM are reported.

Results: Both LW (44.5±1.3 Kg) and BC (3.3±0.8 units) did not differ ($P > 0.26$) between treatments. In addition, the serum levels (4.94 ng mL⁻¹), pulsatility (3.8 pulses) and the area under the curve (1,804.4 units) of LH did not differ ($P > 0.05$) during the follicular phase between treatments. However, an increased antral follicular population ($P = 0.05$; 3.40 vs. 2.18) favored to the GLUT-group. Results confirmed an acute effect of the short-term supplementation with L-glutamate, stimulating the steroidogenic activity while promoting a greater development of the antral follicular population. The last, without changes in the secretion pattern of LH, considering concentration, pulsatility and area under the curve of LH. The site of glutamate action, at brain or ovarian level, cannot be deciphered without further work, but there are some interesting possibilities. In the hypothalamus, the excitatory amino acid glutamate plays a critical role in the activation of gonadotropin secretion, particularly, in the production of the preovulatory surge of

GnRH. Glutamatergic neurons involved in the control of GnRH neurons contain kisspeptin+GPR54, a molecular complex which play a crucial role as essential regulator of the gonadotropic axis. Besides, ionotropic glutamate receptors have been identified at ovarian level while glutamate itself is present in antral fluid at several stages of follicular development.

Conclusions: Results confirmed a short-term-acute effect of the precision supplementation with L-glutamate during specific windows of the estrous cycle upon follicular growth in adult goats, stimulating the steroidogenic pathway while promoting a greater development of the antral follicular population. The last physiological scenario occurred without changes in the secretion pattern of LH, considering overall concentration, pulsatility and area under the curve of LH. Even so, the precise site of glutamate action, either at hypothalamic centers or at ovarian level, remains to be deciphered; results may encompass translational applications.

Genetic parameters for health traits in a multi-breed sheep population

Áine C. O' Brien^{1,2}; Noirin McHugh¹; Eamon Wall³; Kevin McDermott³; Shane Randles³; Sean Fair²; Donagh P. Berry¹

¹Animal and Grassland Research and Innovation Centre, Teagasc, Moorepark, Fermoy, Co. Cork, ²Department of Life Sciences, Faculty of Science and Engineering, University of Limerick, Limerick, ³Sheep Ireland, Highfield House, Bandon, Co. Cork, Ireland

Objectives: The objective of the study was to quantify the genetic variation present in three key health related traits (i.e., lameness, dagginess and mastitis) and their genetic association with body-related traits (i.e., body condition score (BCS), live weight (LW), muscle depth and fat depth) in a multi-breed Irish sheep population.

Materials and Methods: Records were available on 35,282 animals (i.e., lambs and adults) from the Sheep Ireland database between the years 2009 and 2015, inclusive. Each trait was measured by trained technicians. Mastitis was measured as a binary trait (0=no mastitis; 1=mastitis). Lameness was visually assessed on a 3-point scale (0=not lame, 1=slightly lame, 2=moderately to severely lame). Dagginess, a measure of the build-up (or lack thereof) of faecal material around the hindquarter of the animal, was measured on a 5-point scale: 1=clean to 5=faecal material covering the breech area and extending down the hind legs. Live weight was recorded using a pre-calibrated (electronic) scales. Both muscle depth and fat depth were measured using ultrasound scanning. BCS was subjectively assessed on a scale of 1 (extremely emaciated) to 5 (over-fat). Animals without a known sire were excluded, as were all rams (i.e. male animals ≥ 365 days old) and ewes that had previously been used as embryo transfer donors. Variance components were estimated using linear animal mixed models. Fixed effects included in the model were the breed proportion of the animal, coefficients of heterosis and recombination, parity/age group, and the age difference from the median of each parity/age group; an additive genetic effect and residual effect were both fitted as random terms with the animal pedigree considered via a numerator relationship matrix.

Results: The heritability estimate for dagginess and lameness across all data were 0.13 (SE=0.01) and 0.07 (SE=0.01), respectively. The heritability estimates for LW and BCS were 0.28 (SE=0.02) and 0.12 (SE=0.02), respectively. Mastitis, which was only measured in ewes, had an estimated heritability of 0.04 (SE=0.04). Muscle depth and fat depth had heritability estimates of 0.05 (SE=0.01) and 0.30 (SE=0.06),

respectively and were measured only in lambs. Body related traits were all strongly phenotypically correlated; the phenotypic correlations between LW and BCS, muscle depth and fat depth were 0.52, 0.42 and 0.26 respectively. The phenotypic correlations between dagginess and BCS, LW and muscle depth were -0.09, -0.03, and -0.06, respectively. Weak genetic and phenotypic correlation existed among lameness, mastitis and dagginess. Similarly, weak genetic correlations existed between LW and dagginess, or between lameness and mastitis while the phenotypic correlations between LW and dagginess, lameness and mastitis were -0.03, -0.09 and -0.03, respectively. The genetic correlation between lameness and BCS was -0.51 (SE=0.13) while the genetic correlation between dagginess and muscle depth was -0.26 (SE=0.13). Body related traits were strongly correlated with each other; the genetic correlations between BCS and LW, muscle depth and fat depth were 0.76, 0.45 and 0.40, respectively. The genetic correlations between LW and muscle depth and LW and fat depth were both 0.75, while the correlation between muscle depth and fat depth was 0.81.

Conclusions: Ample genetic variation exists for all the health traits investigated in the current study indicate that genetic improvement in dagginess, lameness and mastitis is possible. Furthermore, knowledge of the correlations between the health and production traits indicates that it is possible to select for improved health traits without compromising on production gains.

Staphylococcus aureus Associated With Subclinical Mastitis From Sheep Meat Flocks From Small Production Units In Two Regions Of The State Of Mexico.

Velazquez-Ordoñez Valente¹; Benjamin Valladares Caranza¹; Jorge P. Acosta-Dibarrat¹; María Uxua Alonso-Fresan¹; Jose Luis Zamora-Espinosa¹; Soledad Díaz Zarco¹; Abigail Gil-Gil¹; Jose Luis Carlos Bedolla-Cedeño¹; Rodolfo Lucio-Domínguez¹ and Red de Cuerpos Académicos en Salud Animal e Inocuidad Alimentaria

¹UNIVERSIDAD AUTONOMA DEL ESTADO DE MEXICO, TOLUCA, Mexico

Objectives: The objective was to determine the frequency of subclinical mastitis and associated pathogens with mammary gland infection in sheep meat flocks from small production units in two regions of the State of Mexico.

Materials and Methods: A longitudinal descriptive study was conducted using a non-probabilistic convenience sampling in sheep production areas in the central-eastern and northeastern region of the state of Mexico in smallholder semi-intensive sheep farms where the following meat breeds were found: Suffolk, Hampshire, Corriedale and hybrids with prevalent creole flocks in the north-eastern region. 625 composite samples from the udder of lactating ewes were collected; lambs were separated one hour prior to hand milk. Milk was obtained as a single composite sample in sterile plastic tubes, kept at 4 °C until microbiological tests were run. Subclinical mastitis was detected using California test. Reactions were interpreted as negative, trace, one, two and three. For microbial isolation milk was homogenized at 25 °C, and 0.01 ml of milk was inoculated on blood and MacConkey agar plates, and incubated at 37 °C for 18 to 24 hours. Colony forming units were identified by Gram staining, coagulase, Voges-Proskauer, catalase, oxidase, triple sugar iron (TSI), and motility tests. Final identification was performed using

ApiStaph and API20E system. The isolated groups of pathogens were classified as contagious (*S. aureus* and *St. agalactiae*), environmental (*Escherichia coli*, *Klebsiella* spp, *Enterobacter* spp, *Streptococcus* none *agalactiae*), and as minor (coagulase negative *Staphylococcus*). Results were evaluated by testing estimated proportions ($p < 0.05$). Analysis of the results was made through the frequencies of isolation observed, subclinical mastitis and regional distribution in sheep flock units.

Results: Subclinical mastitis frequency was 43%, and 0.4% for sheep with clinical mastitis, different in all sampled regions ($p < 0.001$). Isolated pathogens were (%): *Staphylococcus aureus* 36.2, *Staphylococcus coagulasa* negativos 12.5, *Streptococcus* spp. 6.5%, *M. hemolítica* 5.4., *Klebsiella* spp 2.8, *Pasteurella multocida* 0.2, *γ* *Arcanobacterium pyogenes* 0.4. The general isolation rate was high in the different regions with no associations according to the breed ($p < 0.05$). Subclinical mastitis is mainly related with *Staphylococcus aureus*, negative coagulase *Staphylococcus*, and in less proportion *Streptococcus* spp and other environmental pathogens. Clinical mastitis cases were directly related with *S. aureus*, *Streptococcus* spp., and *A. pyogenes*.

Conclusions: We conclude that *S. aureus* and coagulase-negative *Staphylococcus* showed a wide distribution in sheep flocks compromising the health of the mammary gland and its capability to produce milk for rearing of lambs, therefore affecting sheep meat production systems from smallholder sheep farms.

P01-001-108

Patterns of heat tolerance in different sheep breeds in Brazil

Concepta McManus¹Bruno S. L. Dallago¹Candice B. Tanure¹Paulo Ricardo M. Lima¹Vanessa Peripolli¹

¹University of Brasilia, Brasilia, Brazil

Objectives: Physiological mechanisms which limit and adjust cold and heat tolerance are regaining interest due to global warming, therefore this study aimed to determine regions of Brazil suitable for sheep breeds with differing in heat adaptation.

Materials and Methods: Data were collected on 80 sheep from 11 breeds using a total of 1077 observations. Breeds included Australian Merino, Polwarth/Ideal, Corriedale, Romney Marsh and Crioula for wool sheep. Short wool sheep included Hampshire Down, Texel, Ile de France and Suffolk, while hair sheep included Santa Inês and Dorper. All sheep were adult and non-lactating. Eye temperatures (T_{eye}) were taken in both eyes using an infrared camera (FLIR®) and average temperature calculated. The respiratory rate (RR) was assessed by movement of the chest wall and abdomen and counted. During the evaluation, the animals were at rest and were not feeding or ruminating. The air temperature (T_{air}) and relative humidity (RH) of the housing were evaluated at several points using a digital thermo-hygrometer. Measurements of the shed conditions - T_{air} and RH - and the physiological parameters of animals - T_{eye} and RR - were taken three times a day: in the morning between 7 and 9; afternoon between 13 and 15 and night between 18 and 20 hours. For data collection there was no interference in the behavior and physiological responses of animals due to management as the sheep were not handled or disturbed during the experiment. The temperature humidity index (THI) was calculated from temperature and humidity data. Data were analysed, using broken line regression to determine THI, T_{air} and RH limits by breed for respiration rate and T_{eye} . These inflexion points were then used to determine regions suitable for sheep rearing by

breed, using mean THI by municipality and spatialized using ARCGIS®.

Results: The mean THI (THI_m) was 20.30, ranging from 14.02 to 31.44. There was an increase in RR and T_{eye} with T_{air} and THI and a decrease in RR with an increase in RH. Correlations between THI and THI_m were 0.99. The inflexion point for RR indicates the point (THI, T_{air} or RH) that the animal changes its respiration to compensate for environmental changes, while for T_{eye} inflexion point is the value where physiological mechanisms no longer can maintain the core temperature under control. The hair breeds tended to have faster reactions to increases in THI and T_{air} , as expected. Variation in responses for Dorper, Santa Ines and Ile de France were more varied and in general lower. T_{eye} were highest in Romney, Merino, Ideal and Suffolk, while Crioula showed lower T_{eye} , although it used respiration at a lower temperature managed to maintain T_{eye} at a low level. The Southern region is the region most suitable for all breeds of sheep. Some municipalities in the Southern Region are unsuitable even for rearing Suffolk or Texel breeds, while the Santa Ines can be reared in almost all environments. However, there are some regions where sheep cannot be reared. There is a band of municipalities running from the center-west to the northeast of the country where many sheep breeds would be under stress on an average day. A large portion of the northern region is covered by forest and therefore, although adequate environmental conditions exist, is not used for sheep production.

Conclusions: To determine differing regions of Brazil for sheep breeds in heat adaptation is required to re-evaluate thermal limits, to adjust cold and heat tolerance, for sheep breeding, especially in Brazilian hair sheep.

P01-001-109

A novel ELISA for the detection of caseous lymphadenitis in United States goat herds: Test validation and application in a field setting

Katherine Whitman¹John D. Loy²Bradley Jones³

¹Great Plains Veterinary Educational Center, University of Nebraska, Clay Center, ²Veterinary Diagnostic Center, ³School of Veterinary Medicine and Biomedical Sciences, University of Nebraska, Lincoln, United States

Objectives: Commercially available diagnostics for caseous lymphadenitis (CL) in the United States include bacterial culture and Synergistic Hemolysis Inhibition (SHI) serological testing, whereas ELISA testing is used more extensively outside of the US. ELISA testing may be more economical and because most US diagnostic laboratories have ELISA capabilities, could become more widely available. The objectives of this study were to validate a CL ELISA test commercially available in Europe, then use the ELISA in subsequent field testing to determine CL prevalence in Midwestern United States dairy goat herds.

Materials and Methods: For test validation, goat serum from 78 positive controls and 138 negative controls were collected. Serum samples were tested using ELISA plates (Elitest CLA, MV Diagnostics, Edinburgh, UK), per kit instructions and SHI testing performed at an accredited diagnostic laboratory. Positive and negative results were recorded and compared to known disease status. Sensitivity and specificity of each test was calculated.

For field application of the ELISA test, serum samples (n=543) were collected from 4 dairy goat operations in Kalona, Iowa, US. Herd 1 (HD1)

consisted of 172 head of goats (age: mean=33.3m, median=18m); HD2=121 head (age: mean=45m, median=42m), HD3=122 head (age: mean=63.3m, median=63m), and HD4=128 head (age: mean=59.4m, median=54m). Any goats with abscess formation were also collected for culture. Prevalence of CL was determined for each herd, and ELISA test results were subsequently compared to culture results.

Results: All 138 negative status goats were seronegative with the ELISA and a subset of 67 negative status goats were also seronegative with the SHI test. 9/78 goats that were culture positive were negative on the ELISA (11.5% false negative), and 4/78 culture positive goats were negative with the SHI test (5.13% false negative). The sensitivity and specificity for the ELISA was 88.46% and 100%, respectively. The sensitivity and specificity for the SHI test was 94.87% and 100%, respectively. Agreement between the two serologic tests was evaluated using Kappa Statistic at 0.90 (95% CI: 0.83-0.97).

Using the ELISA in a commercial setting, the total seroprevalence of CL in herds that had known infections was 77.8%, and the prevalence of culture positive goats was 5%. The prevalence within each of the four herds varied; prevalence in HD1=65.7% (113/172), HD2=92.6% (112/121), HD3=85.2% (104/122), and HD4=77.34% (99/128). When goats from these herds that were exhibiting clinical signs were sampled for culture, 26/27 (96%) culture positive goats were also positive with the ELISA.

Conclusions: In this population, either the ELISA or SHI test could be used to achieve similar results and sensitivity and specificity were high for both tests. However, variations between sensitivity and specificity in previous studies indicate the need case-controlled studies over a wider geographic population. The field study showed that culling all seropositive animals could nearly depopulate all herds, and negative status could not be guaranteed. Therefore, in high prevalence herds, clearer understanding of risk factors for abscess formation and a stronger focus on management rather than eradication needs to be evaluated.

P01-001-110

Caprine Arthritis Encephalitis (CAE) and Maedi-Visna by AGID and PCR in goat and sheep herds from State of Rio de Janeiro, Brazil

Patricia Mayumi D. O. L. Abe¹·Fernanda Carla C. Aguiar¹Daniela S. José¹Mario Felipe A. Balara²Nathalie C. Cunha¹Juliana F. Almeida¹Virginia L. D. A. Pereira¹Elmiro R. Nascimento¹

¹Saúde Coletiva Veterinária e Saúde Pública, ²Patologia e Clínica Veterinária, Universidade Federal Fluminense, Niterói, Brazil

Objectives: Caprine Arthritis Encephalitis (CAE) and Maedi-Visna (MV) are infectious multisystemic diseases of chronic nature, caused by Lentivirus group, which determines economic importance to sheep and goat industry due to production losses and trade barriers. Both diseases are regulated by the Sheep and Goat Health National Program of the Ministry of Agriculture, Livestock and Supply, Brazil. In order to investigate these lentiviruses, sheep and goat blood samples were collected in the period of 2013 to 2015, in seven farms in the state of Rio de Janeiro, Brazil.

Materials and Methods: A total of 242 sheep, distributed in farms A (n = 95), B (n = 36), C (n = 65), D (n = 30) and E (n = 16) had serum samples tested for Maedi-Visna and CAE by Agarose Gel Immunodiffusion (AGID). Farms A, B and C adopted the semi-intensive system of

production, while the farm D had an intensive system for blood products and E, belonging to the Brazilian Army (IBEX), sheep found themselves confined. Also, 57 serum samples from goats were collected from two farms in the state of Rio de Janeiro (29 and 28 sera from F and G establishments, respectively). These properties had adopted systems of semi-intensive and intensive breeding respectively. For diagnostic of Lentivirus by Nested-PCR, blood samples of 26 sheep from farm A and 11 goats (farm G) were collected with EDTA in the same period described above. For AGID was used a commercial kit (Biovetech®), following the manufacturer's instructions. In the first stage of Nested-PCR (Barlough et al., 1994), 34µL of ultra-pure water, 5µL 10x buffer, 2 µL 50 mM MgCl₂, 2 µL 10mM dNTP, 1.5 µL of each primer and 0.2 µL of Taq DNA polymerase 5U were used for obtaining an "amplicon" of 297bp. Then, in the second stage, 36µL of ultra-pure water, 5µL 10x buffer, 2 µL 50 mM MgCl₂, 2 µL 10mM dNTP, 1.5 µL of each primer and 1 µL of Taq polymerase 5U were used to the second Nested-PCR amplification, generating an "amplicon" of 185bp. The amplifications were obtained in a thermocycler programmed. The amplified products were subjected to agarose gel electrophoresis and visualized under UV light at transilluminator.

Results: We observed that 2.48% (06/242) sera sheep were reactive for Maedi-Visna, being obtained from two farms (A and C). While for CAE, 2.89% (07/242) of the tested sheep sera were reactive, all from one establishment (A). According to the literature, it is expected higher prevalence of lentiviruses in intensive farming systems, but there was no positive animal on the premises D and E. Facilities A and C showed greater flow of buying and selling animals, and probably this rotation without proper sanitary control, had worked as a potential risk factor for the spread of the virus.

In addition, four samples of sheep sera were reactive for CAE, as for Maedi-visna by AGID, which can be explained by the mixed infection or cross-reaction, necessitating a greater in-depth study. For this elucidation, a sequence to typify Lentivirus can be identified after completion of PCR. Already, in two herds of goats, the positivity of animals tested for CAE, by AGID, was 29.82% (17/57). The results of PCR in sheep samples demonstrated that 11.54% (3/26) were positive. Although AGID and ELISA constitute the tests recommended by OIE, three sheep samples were positive by PCR, but, at the same time, none of them were reactive by AGID for CAE and Maedi-Visna. This fact can be justified by the absence of seroconversion in the initial phase of infection and / or the greater sensitivity of PCR. Besides that, 18.18% (2/11) of goats were positive by PCR. The use of PCR together AGID improved diagnostic efficacy, particularly in cases of animals with serology negative or doubtful.

Conclusions: In this study, it was found reactive samples by AGID for MV and CAE, both in sheep and goats herds; as well as mixed infection or cross-reaction, in the State of Rio de Janeiro. It was evident the importance of epidemiological monitoring for obtaining the incidence of these lentiviruses. Additionally, the use in conjunction of AGID and PCR improved the diagnostic accuracy, especially in cases of doubtful or negative serology.

Reproductive Performance Of Nulliparous Anovulatory Ewes Exposed To Glutamate And Or Testosterone Treated Rams During Increased Photoperiods In Mexico

César Meza-Herrera¹,¹Guadalupe Calderón-Leyva²,²Oscar Ángel-García³,³Juan R. Luna-Orozco⁴,⁴Francisco G. Véliz-Deras⁵,⁵Gerardo Arellano-Rodríguez³,³Rafael Rodríguez-Martínez⁵

¹URUZA. Universidad Autónoma Chapingo, Bermejillo, Dgo., ²Ciencias Médico Veterinarias, ³Producción Animal, Universidad Autónoma Agraria Antonio Narro, Torreón, Coahuila, ⁴CBTA N° 1., La Partida, Torreón, Coahuila, ⁵Ciencias Médico Veterinarias, Universidad Autónoma Agraria Antonio Narro, Torreón, Coahuila, Mexico

Objectives: The aim of this study was to evaluate the possible effect of glutamate and(or) testosterone treated males upon the male sexual behavior and the reproductive outcomes of nulliparous Dorper ewes once exposed to such males during the natural spring anestrus season in Northern Mexico (25° N, 103° W).

Materials and Methods: 8 Dorper rams, and 55 nulliparous-anovulatory ewes were used. Two transrectal ultrasound screenings were performed on days -14 and -7 prior the experimental breeding to confirm absence of corpora lutea. Thereafter, prior exposure to males, each ewe received a total of 60 mg i.m. of progesterone divided in 3 doses (20 mg each) on days -6, -4 and -2 prior to the male effect, in order to avoid short cycles and to promote ovulation accompanied by standing estrus. Both ewes and rams were divided into four experimental groups, 1). Glutamate Group (GG, 14 ewes exposed to two rams treated 7 mg kg⁻¹ BW of L-Glutamate i.m. every 4d x 30d; 2). Testosterone Group (TG, 14 ewes exposed to two rams treated with 0.5 ml saline every 3d x 15d + 25 mg of testosterone i.m. every 3d x 15d); 3). Glutamate + Testosterone Group, (GTG, 14 ewes + two rams treated with 7 mg kg⁻¹ BW of L-Glutamate every 4d x 30d + 25 mg of testosterone i.m. every 3d x 15d, the last 15d) and 4). Control Group (CONT, 13 ewes exposed to two rams treated with 0.5 mL of saline i.m. every 4d x 30d). Each group was placed at different pen, at a distance of 100 m among them. The frequency of the appetitive sexual behaviors (ASB) and consummatory sexual behavior (CSB) were daily recorded during 2-h x 2d, and from the first day of contact with the males, reproductive activity from anovulatory ewes exposed to the male effect, the onset of estrus was recorded. Thereafter, the embryo implantation rate was determined on d-45 from male exposure. Data were analyzed with X², while onset of estrus were analyzed using t test.

Results: Regarding the ASB, the frequency of behaviors of the GGT, GG, CONT and TG groups were 43 vs 29, 18, 11%, respectively; differences (P<0.05) were observed only between TG and CONT. With respect to the CSB, the best response was depicted by the GG and GTG (32% each; P>0.05), followed by the GC (20%) with the lowest response depicted by the TG (3%; P<0.05). When evaluating the female response upon exposition to the different treated males, those ewes exposed to the GG-males depicted the best reproductive response since they showed not only the shortest interval to estrus (38.6±2.6 h) but also the highest estrus (100%) and ovulatory (100%) rates as well as the highest embryonic implantation rate (100%).

Conclusions: Such ovarian and reproductive responses depicted by these nulliparous Dorper ewes during the natural anestrus season while exposed to males treated with glutamate (GG) and glutamate + testosterone (GTG) are of paramount and potential importance to promote the sustainability. The last being of paramount importance to different animal production system depicting reproductive seasonality.

Nebulization Therapy In Small Ruminants, 21 Cases (2000-2015)

Joe Smith¹,¹John Angelos²,²Meera Heller²

¹Veterinary Diagnostic and Production Animal Medicine, Iowa State University, Ames, ²Department of Medicine and Epidemiology, University of California Davis, Davis, United States

Objectives: The objectives of this study were to identify the agents and dosages utilized for nebulization therapy in small ruminants at a university teaching hospital. Additional objectives were to describe outcomes vs non-nebulized cases and report any complications arising from therapy.

Materials and Methods: Medical records of small ruminants presented to the University of California-Davis Veterinary Medical Teaching Hospital (VMTH) between January 1, 2000 and March 1, 2015 were evaluated for this study. Cases that had undergone nebulization therapy were selected.

A group of control cases of small ruminants that were not nebulized with a diagnosis of pneumonia were collected from the same search period for the same institution. A logistic regression was used to compare outcome between groups with outcome being survival to discharge from the hospital, among other treatment variables.

Results: Fourteen goats and 7 sheep that underwent nebulization were identified, all treated for some form of respiratory disease. Nebulized drugs included antimicrobials, mucolytics, and bronchodilators. In goats, the most commonly nebulized drug was ceftiofur (n=7). Dosages ranged from 1 to 14.5 mg/kg (mean 6.8 mg/kg). In sheep, the most commonly nebulized drug was ceftiofur (n=4). Two goats exhibited respiratory distress during nebulization.

Preliminary regression analysis demonstrated a negative outcome for patients that did not undergo nebulization.

Conclusions: Nebulization appears to be a minimally invasive adjunct for treatment of small ruminant respiratory disease. Practitioners should be aware of non-antimicrobial therapies for treating respiratory disease in small ruminants such as mucolytics and bronchodilators. Dosages higher than previously reported for calves (ceftiofur, 1 mg/kg) may be clinically useful for small ruminants with respiratory disease. Extralabel drug use should be considered when utilizing nebulization therapy. More research in a controlled setting is needed to further evaluate efficacy of nebulization therapies in the treatment of in small ruminants with respiratory disease.

⁴Departament of veterinary Clinics and Surgery, FCAV - Univ. Estadual Paulista, Jaboticabal-SP, Brazil

Objectives: There is a lack of information about the effects of the diet fat source on goat reproduction and acute phase proteins (APP) response. The aim of the present study was evaluate the acute phase proteins profile in eighteen goats fed with different fat sources and submitted to twice-laparoscopic ovum pick-up (LOPU).

Materials and Methods: Eighteen Anglo-Nubian goats were randomly divided into 3 groups based on their diets with different fat sources [soy oil (S, n=6), linseed (L, n=6) and Megalac® (M, n=6)], formulated with 40% concentrate, 60% corn silage and 4% ether extract (in dry matter) from the fat source. The animals were submitted to 15 days adaptation period and, then, an experimental period of 77 days. The LOPU was performed after 36 hours of an ovarian superstimulation protocol [FSH (80mg) + eCG (300IU)], on Day 42 (LOPU1) and Day 70 (LOPU2) of the trial. The blood samples were taken just before each LOPU (D42 and D70), 24 hours (D43 and D71), 72 hours (D45 and D73), five days (D47 and D75) and seven days (D77) after LOPU. The fraction of proteins were obtained by SDS-PAGE. Data were analyzed by ANOVA for repeated measures with Tukey post-hoc test ($p \leq 0.05$) using software R. There were interaction between groups and time and the results are expressed by means \pm sd and capital letters after meaning indicate difference between groups and small letter difference between times. Were found between 16 to 18 proteins and for this study ceruloplasmine (CER, mg/dL) and haptoglobine (HAPT, mg/dL) were elected as relevant.

Results: The CER results on days D42, D43, D45, D47, D70, D71, D73, D75 and D77 of S group are 34.4 ± 13.4 Aa; 26.2 ± 8.95 Aa; 42.7 ± 21.3 Aa; 60.7 ± 23.4 Aa; 35.4 ± 10.2 Aa; 38.9 ± 23.0 Aa; 46.7 ± 27.0 Aa; 34.2 ± 25.4 Aa; 29.1 ± 18.6 Ba; of group L are 56.0 ± 37.5 Aab; 47.0 ± 24.8 Aab; 74.0 ± 50.9 Aa; 47.9 ± 12.2 Aab; 38.0 ± 14.8 Aab; 35.0 ± 9.66 Aab; 29.3 ± 21.9 Ab; 53.9 ± 19.6 Aab and 54.3 ± 21.5 Abab, and in M group are 38.4 ± 17.9 Aa; 47.3 ± 14.5 Aa; 69.6 ± 44.0 Aa; 42.7 ± 25.7 Aa; 52.8 ± 38.5 Aa; 40.5 ± 22.4 Aa; 46.5 ± 10.7 Aa; 43.9 ± 20.6 Aa and 64.3 ± 21.6 Aa. The HAPT results on days D42, D43, D45, D47, D70, D71, D73, D75 and D77 of S group are 16.3 ± 20.6 Bc; 76.1 ± 24.5 Aa; 116 ± 102 Aab; 87.1 ± 73.4 Aab; 20.9 ± 13.6 Abc; 140 ± 123 Aa; 183 ± 176 Aa; 137 ± 174 Aa and 152 ± 218 Aa; of group L are 78.7 ± 64.9 Aab; 124 ± 74.8 Aa; 168 ± 85.7 Aa; 105 ± 78.0 Aa; 19.3 ± 5.03 Ab; 108 ± 34.4 Aa; 148 ± 149 Aa; 176 ± 202 Aa and 136 ± 169 Aab, and of M group are 31.9 ± 25.9 Abc; 106 ± 39.8 Aab; 128 ± 78.8 Aab; 68.2 ± 50.5 Aabc; 46.9 ± 49.4 ; Abc; 258 ± 318 Aa; 89.6 ± 49.9 Aabc; 54.9 ± 38.9 Aabc and 26.8 ± 13.5 Ac. The values of CER were different between moments only in group L with the highest values on D77 and D43 and lowest on D75. The values of HAPT were different between groups only on D42 with the highest values measured on L group and the lowest on C group, in C group the highest value were on D75 and lowest on D42, on L group the biggest value were on D43 and the smaller on D77, in group M the biggest values were on D71 and smaller on D77.

Conclusions: According to our results CER and HAPT were higher on L group and despite what was reported in monogastric animals and humans the enrichment of diet with polyunsaturated fat acids (PUFA) goats fed with higher levels of pufa have a bigger APP response. There might be an influence from the source of dietary fat on APP profile of goats and more studies are necessary to explore these effects.

Reproductive Tract Surgeries in Goats under General Inhalational Anaesthesia

Katarzyna Siewruk ¹; Barbara Lisowska ²; Ricardo Faundez ³; Zdzislaw Gajewski ⁴; Michał Trela ⁵; Michał Dabrowski ⁵; Bartosz Pawlinski ⁵

¹Departament for Animal Reproduction, FVM, Warsaw University of Life Sciences, Warsaw, ²Anesthesiology and Intensive Care, Independent Public Hospital Prof. Adam GrUCA CMPK in Otwock, Otwock, ³Dep. for Animal Reproduction, FVM, Warsaw University of Life Sciences, ⁴Dep. of Animal Reprod, CBB, WCB, Warsaw University of Life Sciences, ⁵Dep. for Animal Reproduction, WCB, CBB, FVM, Warsaw University of Life Sciences, Warsaw, Poland

Objectives: Goat (*Capra hircus*) is gaining acceptance as an established model for research about ruminant reproductive tract physiology. Goats can be gentle, easy to handle and transport, intelligent, affectionate, friendly and clean. The study of oviduct contractility (isthmus and ampulla) near ovulation time in females is still not enough nevertheless overall understanding is vastly important in clinical practice especially in seasonally polyoestral animals. The aim of the study was to record myoelectric activity of the oviduct and uterus in goats following induced oestrus with different synchronisation protocols during breeding season.

Materials and Methods: The 30 polish white landrace goats were enrolled into the study. The elective, surgical, procedure under general inhalational anesthesia (sevoflurane in oxygene) was performed in all animals. The general inhalational anesthesia (sevoflurane in oxygen; Sevoflurane Baxter) with endotracheal intubation following intramuscular premedication (midanium 0,4 mg/kg; Midanium 5mg/ml Polfa Warszawa S.A., ketamine 4mg/kg; Bioketan 50 ml Vetoquinol Biowet PL) and intravenous induction (propofol 4mg/kg; Scanofol 10mg/ml ScanVet Poland) was performed due to the left flank laparotomy. The silicone base silver bipolar electrodes were adapted to be sutured on oviduct and uterine horn. Goats were surgically fitted with TL10M3-D70-EEE (DSI, St. Paul, MN, USA) implants positioned between the abdominal muscles, and 3 silicone electrodes sutured on the left or right oviduct (bulb and isthmus) and the corresponding uterus horn. The myoelectric activity was recorded using the DL10 analog output (DSI) coupled to PowerLab (ADInstruments, Melbourne, Australia) and PC computer. The postoperative antibiotic therapy with amoxicillin 1ml/10kg (Betamox L.A 150mg/ml; ScanVet Poland) in combination with postoperative analgesia meloxicam 0,5 mg/kg (Metacam 5mg/ml; Boehringer Ingelheim Vetmedica) was proceed for 5 days. Goats after the research underwent euthanasia with intravenous injection of phentobarbital 0,3- 0,6 ml/kg (Morbital; Biowet Puławy) to collect tissues for further histopathology examination and to obtain uterine and ovarian explants.

Results: The maintenance of general anaesthesia (sevoflurane in oxygene) was smooth and easier to control compared with general anaesthesia maintenance with isoflurane in oxygene. No complications like heart arrhythmias, respiratory depression and anaphylactic reaction were observed during surgery. The recovery process after endotracheal tube removal was much faster (5 min- standing position) without complication in intensive care room for large animals compared with recovery process after isoflurane administration (15 min). The back to consciousness after sevoflurane anaesthesia is faster than after isoflurane anaesthesia which is preferably especially in ruminants.

Conclusions: General inhalational anesthesia (sevoflurane in oxygene) allows for optimal however safely, painless management of the highly complicated surgeries on reproductive tract in goat model. Furthermore, the medical sciences state of art progress affords application of the latest anaesthetic drugs and techniques allowing to minimize pain and distress in animals.

Hematological and biochemical evaluation of goat whole blood stored in CPDA-1 and CPD/SAG-M bags.

Raimundo A. Barreto Junior ¹; Rejane S. Sousa ²; Marcondes D. Tavares ¹; Isabella O. Barros ¹; Paulo R. Firmino ¹; Jucelio S. Gameleira ¹; Talyta N. Lins ¹; Francisco L. C. Oliveira ²; Antonio Minervino ³; Enrico L. Ortolani ²

¹Department of Animal Science, Federal Rural University of the Semiárid Region, Mossoro, ²Department of Clinical Science, Faculty of Veterinary Medicine, University of Sao Paulo, Sao Paulo, ³Federal University of Western Pará - UFOPA, Santarem, Brazil

Objectives: Considering the variety of blood bags and the different benefits of the substances used, the implementation of different conservation systems in veterinary transfusion medicine should be carefully evaluated. It is important to know which are the alterations that occurring in blood during storage in different animal species. Thus, we aimed to evaluate the hematological and biochemical changes of whole blood of goats stored in CPDA-1 and CPD/SAG-M bags.

Materials and Methods: Seven male, adult, mixed-breed goats were used, weighing an average of 62kg. From each animal 900 ml of whole blood was collected directly into CPDA-1 and CPD/SAG-M plastic bags (450 ml of blood in each bag). Bags were stored for 42 days at an average temperature of 3°C and were daily manually mixed for 5 minutes. Blood samples were taken from the bags at seven moments: T0 (baseline: immediately after collection of blood), T7d, T14d, T21d, T28d, T35d and T42d (seven, 14, 21, 28, 35 and 42 days after collection). In every moment, hematological (number of erythrocytes, leukocytes, packed cell volume and total plasma hemoglobin, degree of hemolysis and mean corpuscular volume), biochemical (glucose, lactate, sodium, potassium and total protein.) and microbiological (incubation in Agar blood) analyses were performed.

Results: The difference between the volume of diluent contained in bags made it difficult to compare results. In both bags there was an increase ($p < 0.05$) in plasma hemoglobin, degree of hemolysis and lactate during the storage period and a reduction of total hemoglobin and pH. No alterations were observed in the number of erythrocytes, glucose, sodium and potassium when compared to baseline. The CPD/SAG-M bag showed lower values of erythrocytes, leukocytes, packed cell volume, total hemoglobin and sodium when compared with CPDA-1, probably due to the dilution, but presented a higher ($p < 0.05$) degree of hemolysis and plasma hemoglobin.

Conclusions: The changes observed in goat whole blood stored for 42 days in CPDA-1 and CPD/SAG-M, were not sufficient to invalidate the use of blood stored for transfusion purpose, however, considering our results and the lower price of CPDA-1 bags, these are most advantageous for the storage of goat blood.

Objectives: The caseous lymphadenitis is a disease caused by a gram positive bacteria *Corynebacterium pseudotuberculosis*, encountered in mucous membranes and in the soil, which can remain viable for several months. After contamination by oral, respiratory or skin wound, the bacteria are phagocytosed by neutrophils and macrophages and sequestered to regional lymph nodes, which form pyogranulomas. The objective of this paper is to report a case of brain abscess caused by *Corynebacterium pseudotuberculosis*, not reported in the consulted literature.

Materials and Methods: A male goat breed Boer three-year-old has been evaluated with history of ataxia, apathy, dyspnea and progressive weight loss for 45 days. On clinical examination it was observed dyspnea, ataxia of the hind limbs, enlarged lymph nodes, rumen hypomotility, hypermetria and proprioceptive deficit in the hind limbs, especially in the right side. The hemogram revealed increased fibrinogen (1000g / dL) and inversion of the ratio of neutrophil leucocytes and (3: 1). He was suspected of bacteremia by *C. pseudotuberculosis* due to lung infection, for which it was prescribed florfenicol for 15 days. After 18 days, the patient was more ataxic, walked around in a circle, had lip and eyelid ptoses and mydriasis in the right side of the face, and seizures in 20min intervals. Due to the worsening of clinical signs, the animal was euthanized.

Results: At necropsy was observed pus in prescapular, mandibular lymph nodes and increased mediastinal lymph nodes, pulmonary emphysema and pericardial adhesion in cranial lung lobes. In the central nervous system was found an abscess of 5cm diameter containing pus close to the occipital cortex and left cortex temporal. Histologically, the white matter of the brain had extensive focal areas of cell necrosis, with intense increase of mononuclear cells mostly associated with foamy macrophages and astrocytes in astrogliosis process, as well as rare presence of giant cells. Pus found inside the brain underwent microbiological analysis, which was isolated *Corynebacterium pseudotuberculosis*. The exam of the patient on the farm enables to check the ambient conditions in which it was kept, plus the herd as a whole, which helped in drafting the presumptive diagnosis and therapeutic management. In addition, understanding of the epidemiology of the region is an important diagnostic tool in herd medicine. The *C. pseudotuberculosis* has the ability to spread via hematogenous causing abscesses in various organs, however, did not find any report in the literature of brain abscess by that agent. Goat in this report, changes were found in the mediastinal lymph nodes not only, as well as pulmonary abnormalities and pericardial adhesion in lung lobes.

Conclusions: The *Corynebacterium tuberculosis*, the causative agent of lymphadenitis caseous causes the formation of brain abscess. The mechanism is the spread of infection by hematogenous route. The main important way to make the conclusive diagnosis is the necropsy and microbiological culture of the pus.

Cerebral abscess by *Corynebacterium pseudotuberculosis* in caprine: case report

Geane Pagliosa ¹; Anna M. Zimmermann ¹; Flavio H. Carvalho ¹; Alyne Kaaren S. Lima ¹

¹Veterinary Medicine, University of Parana State, Palotina, Brazil

Objectives: This multi-centric Greek field study was conducted on 12 sheep dairy farms to demonstrate the efficacy of Eprinex® Pour-On (5g/L Eprinomectin) in lactating sheep and to then determine whether the observed level of nematode control was associated with improvements in Milk Yield (MY) and Somatic Cell Counts (SCC). The unique pharmacokinetic profile of Eprinomectin enables its registered use in lactating cows in many countries. Numerous publications confirm the potential for milk yield benefits both after Eprinomectin usage in dairy cattle and after effective worm control programs being implemented for sheep.

Materials and Methods: Twelve farms were included and 3 trial groups used. For each farm, Group 1 (12 sheep) were not treated whilst sheep in the other two groups (18 in total) received a dose of 1 mg/kg topically of Eprinex on day 0 of the study. Group 2 (12 sheep) received no further treatments whereas group 3 (6 sheep) were treated on two further occasions, 8 weeks apart. Individual fecal samples were collected on day -14 and then weekly from day 0 to day 84 for FEC determination. MY and SCC measurements were routinely collected and were recorded for the study on the same days as the FECs (from day 7). The flocks were seasonally lambing with ewes being included in the study in the early stage of lactation but not necessarily on precisely the same day post-lambing.

Results: All results refer to the average over all the flocks for each group. On day 0, the control FECs ranged from 290-1130 eggs per gram (epg), with an overall average of 676. Groups 2 & 3 ranged from 480-1035 and 325-892 epg with averages of 603 and 595 epg. The majority of nematodes present were identified as *Teladorsagia* spp. At day 84, the control group average was 791 epg with groups 2 and 3 calculated at 226 and 19 epg. Group 2 achieved a low result of 11.1 epg on day 7 (98.2% reduction). The Day 0 MY was not recorded. By day 7, group 2 was producing 50 mL/sheep/day more than the controls, with group 3 sheep producing 34 mL more than group 2. The group weekly production curves were of similar shape over the trial period but the gaps between them widened from day 7, especially between the controls and both of the treated groups. From day 7 to day 84, group 2 produced 10.82L more per sheep than the control group. Group 3 produced 3.26L more per sheep than group 2. The SCC weekly values were recorded on 8 of the 12 farms. On day 7 the average SCC results were 1180, 993 and 911 for groups 1, 2 & 3. The results each week for the control animals trended upwards, reaching 1249 by day 84. Both treated groups trended down and reached 939 and 872 by day 84. Statistical analysis has not been performed on any of these results.

Conclusions: This study confirmed that the topical usage of 1 mg/kg of Eprinomectin in early lactation was effective in reducing FECs. The results also demonstrated a sizeable numerical increase in MY from treatment (10+ L/sheep), with over 75% of the benefit coming from the first treatment, and a noticeable improvement in the SCC in the treated sheep over the study period. These results support the potential for Eprinomectin (Eprinex pour-on) to be an effective anthelmintic for sheep and for its use to be economically beneficial in adult milking sheep. The recommended label dose for cattle is 0.5 mg/kg.

Eprinex is a registered trademark of Merial Limited.

Comparative genomic identification of β -defensin genes in the *Ovis aries* genome

Thomas Hall¹, Emma Finlay¹, Kieran Meade¹, Sean Fair²

¹Animal & Bioscience Research, Teagasc, Grange, Co. Meath, Ireland.,

²Department of Life Sciences, Faculty of Science and Engineering, University of Limerick, Limerick, Ireland

Objectives: β -defensins are small, cationic, antimicrobial peptides that play a role in immunoregulation across all vertebrates. Though bovine β -defensin genes have been well characterised recently, the genes in *Ovis aries* (domestic sheep) have been poorly annotated, with the majority of genes only identified by automated gene prediction algorithms. The objective of this study was therefore to use a comparative genomics approach to identify and functionally characterise the β -defensin gene repertoire in sheep.

Materials and Methods: In this study, we use all 57 bovine β -defensin genes to find orthologous sequences in the most recent version of the sheep genome. Blast hits with less than 70% identity and 50% coverage were omitted and those with sufficient identity were analysed using BLAST-like alignment tool (BLAT) in order to find their chromosomal location. BioEdit software was used to perform multiple sequence alignments to determine the protein sequence similarity. Putative defensin encoding sequences were then annotated via a phylogenetic analysis using MEGA software.

Results: Of the 57 genes found in the Bovine genome, 25 were found to have close genomic matches, with a large cluster of those genes found on sheep chromosome 13 and smaller cluster found on chromosome 26. Two novel genes were discovered on chromosome 13 and show highest similarity to that of bBD125a and bBD128. As well as novel genes, 10 genes previously annotated as variations of oBD118 and oBD119 have been newly identified as oBD132, oBD142 and oBD117-124. In the chromosome 26 cluster, one gene was found to match fourteen different bovine genes on chromosome 27 with almost uniform similarity. Preliminary comparative analysis of the gene suggests its function may be most similar to that of lingual antimicrobial peptide (LAP).

Conclusions: The identified oBD genes on chromosome 13 illustrate a greater level of defensin gene complexity within the sheep genome than previously thought. The order of these genes correspond directly with bovine chromosome 13, indicating synteny between these two regions. The lack of variety of genes on sheep chromosome 26 in comparison to bovine chromosome 27 suggests a bovine specific expansion, possibly in response to host specific pathogenic threats. This variation may explain the divergent susceptibility of both species to diseases which affect ruminants.

Risks and Managing Copper Deficiency in Sheep and Goats

Robert Van Saun^{1*}

¹Veterinary & Biomedical Sciences, Pennsylvania State University, University Park, United States

Objectives: Copper related disease issues are well-characterized in ruminant species. Sheep are well-known to be sensitive to copper toxicity and often it is limited in the diet. Microbial-induced ruminal interactions between dietary copper (Cu), molybdenum (Mo) and sulfur (S) have been intensively studied and recognized in managing Cu nutrition of ruminants. This is a case study where copper deficiency presented as stillborn and weak lambs and kids and the objective was to define and correct underlying issue to improve animal health and performance.

Materials and Methods: The case study farm raises sheep and goat for meat production. The flock consists of 250 ewes (Finn, Dorset, Suffolk and crossbreds) and 60 Boer does with 200% and 185% lambing and kidding percentage, respectively. Animals are intensively managed and fed a total mixed ration (TMR) throughout the year. All forages are raised locally. Approximately 6 years previous a down Finn ewe was diagnosed with demyelination and nursing kids were diagnosed with enzootic ataxia. Following these initial problems the flock experienced a high rate (17-25%) of stillborn lambs and kids as well as weak neonates with high mortality within 3-4 days of life. Reproductive performance of ewes and does was considered good with 90-95% pregnancy within two service periods. Diagnostic samples of lamb and kid mortalities were submitted to the Animal Diagnostic Laboratory at Pennsylvania State University for a flock workup. Hepatic liver mineral concentrations and vitamins A and E were determined and reported on dry weight (DW) basis. Feed ingredient analyses were completed on a yearly basis. Once diagnosis was made, dietary modification was used to correct the situation and monitored over a 3-year period.

Results: Stillborn kids submitted to the diagnostic laboratory showed no gross abnormalities on necropsy and no positive microbiologic findings. Previous diagnostic investigations showed no infectious causes for the kid and lamb deaths. Hepatic Cu and molybdenum (Mo) in 9 kids was $28.6 \pm 22.2 \mu\text{g/g DW}$ (reference: 75-300 $\mu\text{g/g DW}$) and $3.6 \pm 1.1 \mu\text{g/g DW}$ (reference: 1.5-3.0 $\mu\text{g/g DW}$). Four dead lambs had 36.3 ± 16.7 (reference: 60-300 $\mu\text{g/g DW}$) and $1.9 \pm 0.6 \mu\text{g/g DW}$ hepatic Cu and Mo concentrations, respectively. Similarly, 3 affected ewes had liver Cu and Mo concentrations of 18 ± 13.1 and $3.3 \pm 1.6 \mu\text{g/g DW}$, respectively. Flock diets in 2012 consisted primarily of corn silage and oatlage with additional protein and mineral/vitamin supplements. Forage Cu and Mo content was 6.6 and 5.48 ppm and 7.4 and 5.3 ppm for corn silage and oatlage, respectively. Intent of dietary modification was to increase dietary Cu (37 ppm) supplementation to a level to maintain a 7-8:1 Cu:Mo ratio in the diet resulting in a total dietary Cu concentration of 29 ppm. Lamb and kid losses the following year were reduced in half (6-8% total losses). Forages in 2013 had similar Cu and Mo concentrations and a high Cu diet was fed to pregnant ewes and does with similar positive responses in lamb and kid survival. In 2015 the flock experienced severe (90-95%) lamb losses in all Suffolk or Suffolk cross ewes. In late 2014 a new alfalfa forage was fed to pregnant ewes that was determined to contain 15.4 ppm Cu and 22.1 ppm Mo. Removal of this forage from gestation diets for later lambing ewes reduced lamb losses.

Conclusions: This was an unusual clinical presentation of Cu deficiency as stillbirths and weak neonates are not commonly considered a consequence of Cu deficiency. High concentration of forage Mo (>5.5 ppm DM) relative to Cu (< 12 ppm DM) was responsible for low dietary Cu availability. Recommended dietary Cu:Mo ratio for sheep and goats is 6-8:1 and 6-10:1, respectively. This case study underscores the need to have forages evaluated for Mo and S status in evaluating level of dietary Cu supplementation to ensure adequate availability.

¹Department of Veterinary Preventive Medicine, Universidade Estadual de Londrina, Londrina, ²School of Veterinary Medicine, Universidade Norte do Paraná, Arapongas, ³Department of Veterinary Clinics, Universidade Estadual de Londrina, Londrina, Brazil

Objectives: Histophilosis is disease complex caused by the gram negative bacterium *Histophilus somni* (formerly *Haemophilus somnus*), which involves several clinical syndromes including thrombotic meningoencephalitis (TME), pleuritis, arthritis, bronchopneumonia, septicemia, myocarditis, infertility, and abortion in ruminants. However, the disease occurs predominantly in cattle with sporadic reports in several species of small ruminants. The objectives of this study were to describe the pathological manifestations and molecular finding associated with *H. somni* in sheep from Southern Brazil

Materials and Methods: Sheep (n=9) from this study were from different geographical locations within the state of Paraná, southern Brazil. The clinical manifestations of all animals were observed and a routine necropsy was done soon after death. Selected tissues were fixed by immersion in 10% buffered formalin solution and routinely processed for histopathological evaluation. Duplicate sections of the selected organs (brain, lungs, and heart) were collected freshly during necropsy, and maintained at -80°C until processed for molecular diagnostics. Nucleic acids extracted from tissue fragments of all animals, were used in PCR assays designed to amplify specific amplicons of major bacterial pathogens of ruminants. These assays targeting the 16s rRNA gene of *H. somni*, species and type-specific isolates of *Pasteurella multocida*, and the *lktC-artJ* intergenic region of *Mannheimia haemolytica*. Further, a PCR assay to identify the *rpoB* gene of *Trueperella pyogenes* was done in animal with abscesses. Positive controls and negative controls were included in all PCR assays. PCR products were separated by electrophoresis in 2% agarose gels, stained with ethidium bromide, and examined under ultraviolet light. The amplified PCR products were then purified and submitted for direct sequencing.

Results: Sheep were of different breeds and both genders (8, males; 1, females), and a fetus of one ewe. The principal clinical manifestations were respiratory difficulties (n=7) and apathy (n=3); three ewes had a history of abortion. Significant pathological findings included bronchopneumonia (n=6), necrotizing myocarditis (n=4), thrombotic hepatitis and meningoencephalitis (n=2), pulmonary abscesses (n=2), thrombotic nephritis (n=1), and pulmonary edema and congestion (n=1). *H. somni* DNA was amplified from multiple tissues of all sheep and the fetus. In addition, *T. pyogenes* DNA was amplified from the pulmonary abscesses of one sheep; this animal also contained *H. somni* DNA in multiple tissues. Direct sequencing confirmed the *H. somni* and *T. pyogenes* PCR results. Bacterial DNA was not amplified from the *P. multocida* and *M. haemolytica* PCR assays.

Conclusions: The pathological finding observed during this investigation are consistent with previous descriptions of *H. somni* in ruminants. Confirmation of the participation of *H. somni* in these lesions was confirmed by PCR and sequencing. Further, the amplifying of *T. pyogenes* DNA in a sheep with histophilosis indicates a mixed infection in this animal. Taken together, this study has identified several syndromes of histophilosis (bronchopneumonia, myocarditis, TME, and abortion) in sheep, and support the theory that *H. somni* is an emerging infectious disease pathogen of ruminants from Brazil.

Effect of Exposure Males to Alternated and Non-Alternated Estrogenized Females and Subsequently Exposed to Anestrous Goats

Juan M. Guillen¹ Cesar A. Meza-Herrera² Zurisaday S. Jimenez¹ Raymundo Rivas-Muñoz³ Evaristo Carrillo³ Rafael Rodriguez-Martinez¹ Francisco Veliz¹

¹CMV, Universidad Autónoma Agraria Antonio Narro, Torreón, Coahuila, ²URUZA, UACH, Gomez Palacio, ³Instituto Tecnológico de Torreón, Torreón, Coahuila, Mexico

Objectives: The effectiveness to induce reproductive response in anestrus mix-breed goats exposed to previously stimulated males throughout exposure to alternated and non-alternated estrogenized females during the natural anestrus season in Northern Mexico (26° N), was tested.

Materials and Methods: The first stage of the study started early in March, where bucks (n=12) with homogeneous body weight were randomly distributed to three experimental groups to be exposed to estrogenized females (n=8; 2 mg estradiol cypionate i.m. every 3d x 10d): 1) ALT (n=4), males exposed to four estrogenized females; two of which were changed every 12 h periods (alternated, novelty effect); males remained alone 1 h between alternations, 2) NALT (n=4), males exposed to two estrogenized goats for a 12 h period; males remained alone 1h, then the same goats were reintroduced with the males for another 12 h period (non-alternated. Non-novelty effect), 3) CONT (n=4), males exposed to two non-estrogenized, non-alternated, control-females, treated with saline every 3 d x 10 d; female management was the same as in group NALT. The second stage of the study started on March 15, where males from the three experimental treatments were exposed to adult anovulatory goats (n=72). Thereafter, goats randomly divided in three experimental groups according to the male treatment groups; ALT (n=24), NALT (n=24) and CONT (n=24). Estrus activity was recorded upon male exposure every 12 h x 14 d. On day 10, the percentage of ovulations across treatments was determined and the day 45 was performed to pregnancy rate. Dates regarding estrus onset, ovulation and pregnancy rates were analyzed by X² while estrus latency (h) through t-student test (SYSTAT 12).

Results: The estrus response during first 10 days was higher (P<0.05) in the ALT and NALT groups, regarding the CONT group (80%, 80% and 0%, respectively). Also, estrus latency (hours) differed (P<0.05) among experimental groups with observed respective values of 89±5.85 h, 106.74±5.40 h and non-estrus response for the ALT, NALT and CONT groups. No differences (P>0.05) were observed regarding the ovulatory response between the ALT and NALT groups (63% and 58%), yet the CONT group got the lowest value (0%; P<0.05). In addition, the ALT and NALT groups had highest pregnancy rates (P<0.05; 58% and 58%) regarding the CONT group (0%). Results demonstrated that, when males were primed with estrogenized females, both the “female effect” and the “female novelty effect” were equally able to induce the “male effect” once bucks were subsequently exposed to anovulatory goats, without major differences regarding of the reproductive outcomes observed in these females. The only observed difference was that regarding to the latency of estrus, favoring to the alternated-females; that is, the “female novelty effect”. The control anestrous females never responded to the males exposed to the non-estrogenized female group.

Conclusions: Results could have important practical implications when designing socio-sexual cues-dependent strategies, clean, green and ethical, in order to induce out-of-season reproductive activity in seasonal breeds, particularly in dairy goat production systems.

INDUCTION OF SEXUAL ACTIVITY IN ANESTROUS DORPER EWES USING FGA or P4 plus eCG THROUGHOUT TWO ROUTES OF ADMINISTRATION

Julieta Z. Ordoñez-Morales¹ Gerardo Arellano-Rodríguez² Oscar Ángel-García² Guadalupe Calderón-Leyva¹ Juan R. Luna-Orozco³ Pedro A. Robles-Trillo² César A. Meza-Herrera⁴ Rafael Rodríguez-Martínez¹ Gerardo F. Véliz-Deras¹

¹Ciencias Médico Veterinarias, ²Producción Animal, Universidad Autónoma Agraria Antonio Narro, Torreón, Coahuila, ³CBTA N° 1, La Partida, Torreón, Coahuila, ⁴URUZA. Universidad Autónoma Chapingo, Bermejillo, Dgo., Mexico

Objectives: The aim of this study was to evaluate the effectiveness of two different routes, intravaginal (IV) or intramuscular (IM), of progesterone (P4) or fluorogestone acetate (FGA) + equine chorionic gonadotropin (eCG) upon estrus induction and reproductive performance of Dorper anestrous ewes in Northern Mexico (26° N).

Materials and Methods: In February, Dorper adult anestrous ewes (n=48, 3-5 yr. old) with similar body weight (BW) and body condition score (BCS) were subjected to two transrectal ultrasound screenings (HS-2000, Honda Electronics Co., LTD.) on days -14 and -7 prior the onset of the experimental treatments to confirm absence of functional corpora lutea. Thereafter, ewes were randomly distributed to three experimental groups: 1). IVG (n=14; 41.5±3.0 kg BW, 2.0±0.2 BCS), receiving an intravaginal sponge impregnated with 40 mg of FGA, 2). IMG1 (n=17; 41.7±4.0 kg BW, 2.1±0.2 BCS) receiving 20 mg of progesterone i.m., 5 and 2 days prior eCG administration, and 3). IMG2 (n=17; 40.2±3.5 kg BW, 2.0±0.2 BCS) receiving 20 mg of progesterone i.m. 6 and 3 days prior eCG administration. After progesterone treatments, the three groups were administered a dose of 300 IU eCG i.m. (day 0). On day 10, the percentage of ovulations across treatments was determined by detecting the presence of corpora lutea throughout ultrasonographic scanning (USS; HS-2000, Honda Electronics CO, LTD). Then, on day 45, another transrectal-USS was performed to determine pregnancy rate. Estrus activity, ovarian activity and pregnancy were evaluated by comparing thru X² the daily and cumulative proportions of these variables (MYSTAT 12 X2 program).

Results: Our results showed that estrus response during the first 10 days differed (P<0.05) across treatments with the IVG depicting the largest response (100 %) with respect to IMG1 (53 %) and IMG2 (35%). The same was true regarding ovulation percentage with the largest (P<0.05) value observed in the IVG (93 %) followed by the IMG1 (59 %) and IMG2 (53 %). In addition, the highest pregnancy rate differed across experimental groups with the largest value (P<0.05) depicted by the IVG, followed by IMG1 and IMG2 with 24 %.

Conclusions: Results of this study showed that the use of intravaginal sponges impregnated with FGA during a short period of time (6 days) was the best reproductive strategy to induce estrus in Dorper adult ewe during the anestrous season. Such results arise as an interesting option in the out-of-season reproductive management, mainly of highly seasonal dairy ewes breeds.

P01-001-124

REPRODUCTIVE PERFORMANCE OF ALPINE ANESTROUS GOATS USING TWO DIFFERENT DOSES OF P4 + eCG UNDER NATURAL MATING OR ARTIFICIAL INSEMINATION

Zurisaday Jimenez¹Cesar A. Meza-Herrera²Juan M. Guillen¹Homero Salinas³Evaristo Carrillo⁴Rafael Rodriguez-Martinez¹Fernando Arellano⁵Francisco Veliz^{1*}

¹CMV, Universidad Autónoma Agraria Antonio Narro, Torreón, Coahuila, ²URUZA, UACH, Gomez Palacio, ³INIFAP, Matamoros, Coahuila, ⁴Instituto Tecnológico de Torreón, ⁵PA, Universidad Autónoma Agraria Antonio Narro, Torreón, Coahuila, Mexico

Objectives: The aim of this study was to evaluate the effectiveness of two different doses of progesterone (P4) plus equine chorionic gonadotropic hormone (eCG) during the anestrus season in goats, exposed either to artificial insemination (AI) and natural mating (NM), in northern Mexico (26° N).

Materials and Methods: Sexually active bucks (n=4) and multiparous anestrus Alpine goats (n=40), were considered. Early in May, goats with homogeneous body condition score (3.0±0.11) were randomly distributed to four experimental groups (10 per group): 1). GAI10, receiving 10 mg P4 i.m., 2). GAI20, receiving 20 mg P4 i.m., 3). GNM10, receiving 10 mg P4 i.m. and 4). GNM20, 20 mg P4 i.m. Upon estrus occurrence, the GAI10 and GAI20 goats were inseminated with frozen semen of known fertility while the GNM10 and GNM20 goats were bred by two sexually active and experienced mix-breed adult bucks, of proven libido and fertility. All female goats received a single dose of 100 IU of eCG, 24 h before of administration of P4 (day 0); the interval to the onset of estrus was registered up to day 15. On day 10, the percentage of ovulations across treatments was determined by detecting the presence of corpora lutea throughout ultrasonographic scanning (USS; HS-2000, Honda Electronics CO, LTD). Then, on day 45, another transrectal-USS was performed to determine pregnancy rate. The estrus response, ovulation and pregnancy rates were analyzed by X2 while estrus latency considered a t-student test (SYSTAT 12, Evenston, ILL, USA).

Results: The estrus response during first 10 days was similar (P>0.05) in all groups (GNM10 90%; GNM20 80%; GAI10 100%; GAI20 90%). Also, estrus latency (hours) did not differ (P>0.05) among experimental groups (GNM10 49.40±3.77; GNM20 55.5±4.2; GAI10 46.80±2.15 and GAI20 46.67±2.28). However, the largest ovulation rate (p<0.05) was observed in the GNM10 (90%) and GAI10 (80%) groups with intermediate values in the GNM20 (70%) and the lowest ovulation rate (P>0.05) depicted by the GAI20 group. In addition, the highest pregnancy rate (P<0.05) occurred in the GNM10 (90%) and GAI10 (80%) groups, with the lowest value in the GAI20 (0%). Analyses of the different doses of progesterone, irrespectively of the AI or NM protocol, generated a pregnancy rate of 55% with the 10 mg P4 vs. 20% obtained with 20 mg P4. The obtained results demonstrate that P4 doses of either 10 or 20 mg i.m. + 100 IU of eCG were equally able to induce estrus response (> 80%) in Alpine goats during the anestrus season.

Conclusions: Yet, those goats treated with 10 mg P4 got increased pregnancy rates regarding those treated with 20 mg P4, irrespectively of insemination protocol. These findings are of practical significance when designing estrus induction protocols in seasonal goat breeds; the last emerges as an important implication, particularly to the dairy goat industry.

P01-001-125

The recording of myoelectrical activity of gastrointestinal tract by telemetry electromyography method in sheep

Małgorzata Wielgosz^{1,2*}Małgorzata Domino^{1,2}Bartosz Pawliński¹
²Katarzyna Siewruk^{1,2}Zdzisław Gajewski^{1,2}

¹Large Animal Diseases with Clinic, Warsaw University of Life Sciences, ²Veterinary Research Centre and Center for Biomedical Research, Warsaw, Poland

Objectives: The regulation of gastrointestinal (GI) motility is strongly modulated by different mechanisms. The GI tract contractility is generated by contractions of the myometrial smooth muscle cells that compose most of the forestomachs, abomasum and intestinal wall. The electrical activity of the smooth muscle fibers during contraction or relaxation can be detected as an electromyography (EMG) signal. The aim of the present study was to adapt radiotelemetry technique for EMG recording of the GI as well as evaluated parameters of motility before and during feeding in sheep.

Materials and Methods: The study was carried out using 6 mature crossbred ewes, each weighing 35-40 kg B.W. The animal were kept in metabolic cages throughout the whole experiment. The experiment was started by surgery. Under general anesthesia three silver bipolar electrodes were inserted into muscular layers of the reticulum, the rumen and the abomasum. The combination of electrodes was connected to a three-channel transmitter (TL10M3-D70-EEE, DSI, USA), which was placed under abdominal skin. The EMG signal sent by the implant as radio waves were recorded using the A10/DL10 output- DSI (located approximately 50 cm from cage), coupled to PowerLab and PC computer. Then off-line analysis of EMG signals were performed. Mean amplitude - A [mV], mean RMS (root mean square) [mV], mean duration of electrical activity - D [s] and burst frequency - F [Hz] were analyzed before and during feeding.

Results: The EMG parameters values (mean±SEM) in the abomasum were: A [mV] 0.44±0.01, 0.62±0.01; RMS [mV] 0.14±0.001, 0.19±0.002; D [s] 2.28± 0.04, 2.63±0.04; F [Hz] 0.11, 0.11 before and during feeding respectively. In the rumen were: A [mV] 0.39±0.01, 0.37±0.006; RMS [mV] 0.08±0.001; 0.087±0.001; D [s] 28.62±0.59, 10.92±0.14; F [Hz] 0.02, 0.05 respectively. As well as in the reticulum were: A [mV] 2.30±0.08, 2.01±0.05; RMS [mV] 0.75±0.02, 0.72±0.02; D [s] 13.56±0.27, 12.90±0.21; F [Hz] 0.01, 0.03 respectively. We found that: (1) all measures were obtainable; (2) there were extremely significant differences (P<0.0001) between all measured parameters in each of studied GI regions both before and during feeding; (3) the extremely significant (P<0.0001) increase of D, A, RMS in abomasum and RMS in rumen were observed; (4) the extremely significant (P<0.0001) decrease of D in rumen and significant (P<0.0008) of A in reticulum were observed; (5) there were no differences of A in rumen (P=0.573) as well as D (P=0.052) and RMS (P=0.276) in reticulum between signals recorded before and during feeding respectively; (6) the feeding- depended burst frequency increase in rumen and reticulum were noticed.

Conclusions: It may be concluded that the telemetry electromyography method successfully allowed long term recording of EMG signals from the rumen, reticulum and abomasum in sheep. This reliable method preceded by ordinary surgical procedures allowed to all motility parameters estimation. The preliminary study may provide useful reference values for further investigation.

Comparison of a routine Capillary Electrophoresis method and Single Radial Immunodiffusion assay to measure immunoglobulins in sheep whey colostrum

Carlotta Ceniti¹Vincenzo Lopreiato¹Valeria Maria Morittu¹Francesca Trimboli¹Elisabetta Fratto²Genesio Massimini¹Domenico Britti¹

¹Università Magna Graecia of Catanzaro, ²Università Magna Graecia of Catanzaro, Catanzaro, Italy

Objectives: In early life, colostrum Igs absorption is critical for the protection of the newborn from infectious diseases. Single Radial Immunodiffusion Assay (SRID) is currently considered the gold standard method for the direct measurements of Igs both in colostrum and serum. Capillary Electrophoresis (CE) is an alternative method capable to directly measure Igs in biological liquids. We had demonstrated that a routine CE instrument can measure Igs in sheep colostrum. The aim of this work was to evaluate the relationship between SRID and CE for the measurement of Igs concentration in sheep colostrum.

Materials and Methods: During the summer of 2014, the colostrum from 12 Sarda sheeps, at 6th-7th lactations, was sampled immediately after lambing (T0) and at 24 hours post partum (T24). The blood samples were collected from the corresponding 12 newborn lambs at 24 hours after birth. Colostrum Igs concentration was determined by a routine CE instrument (Minicap, Sebia France), after fat and caseins removal by centrifugation and enzyme clotting (rennet), respectively. Serum Igs concentration was also determined by CE, as routine. Igs peak in the colostrum electropherogram was identified comparing two electropherograms of a same sample obtained before and after Ig subtraction using Protein G Sepharose conjugate (Gammabind G Sepharose, GE Healthcare). Colostrum and serum IgG concentrations were measured by a commercial SRID kit (IDRing® Box – Sheep & Goat IgG TEST; IDBiotech, France) following the manufacturer's instructions. Before statistical analysis, all colostrum CE data (T0 and T24) and all colostrum SRID data (T0 and T24) were respectively pooled on a same distribution. Data were tested for normality of distribution using the Shapiro-Wilk test (SAS Institute Inc., Cary, NC, USA). For each sample type (colostrum and serum), regression analysis between CE and SRID values was calculated by REG procedure of SAS 9.3 (SAS Institute, Inc., Cary, NC, USA). In addition, for each sample type, Pearson correlation test between the used methods was performed. Statistical significance was declared at $P < 0.05$.

Results: The normality distribution test showed that the considered group of data (CE colostrum, SRID colostrum, CE serum, and SRID serum) were normally distributed. The colostrum Igs concentrations, obtained using CE technique and SRID were, on average, 6.58 ± 4.75 g/dL and 6.42 ± 4.90 g/dL, respectively. The linear regression equation for this set of data was $y=0.40247 + 0.96131x$, $r^2 = 0.98$, showing a strong correlation between the methods ($P < 0.0001$). Linear regression equation ($y=-0.10983 + 0.97458x$) on serum results showed a strong correlation ($r^2 = 0.98$) between the methods ($P < 0.0001$).

Conclusions: We found that, in sheep colostrum, Igs values measured by a routine CE method are linearly correlated with IgG values obtained by a SRID assay. Moreover, because it is known that, differently from SRID, CE analysis measures all together the Igs's classes (IgG, IgA, and IgM) and IgGs represents the major class, our results suggest that in CE analysis the contribution of the minor Ig classes is not significant. Finally, the results of our preliminary study indicate that CE may be a useful tool in the measurements of total Igs in colostrum and could be a rapid and simple approach to assess the colostrum quality.

Epidemiology of endoparasites in small ruminants in Austria, impact of clinical parameters and control of anthelmintic resistance

Julia Schoiswohl^{1,*}

¹Department for Farm Animals and Veterinary Public Health, University Clinic for Ruminants, Vienne, Austria

Objectives: The objective of this study was to investigate occurrence of endoparasite infections in small ruminants in Austria and the influence of different Federal States of Austria with different climatic conditions. Additionally, the effect of clinical parameters of endoparasite infestation was evaluated and the control of endoparasites and anthelmintic management were analysed

Materials and Methods: Faecal samples, on the one hand herd samples and on the other hand individual samples from 337 individual animals and 53 small ruminant herds were collected. Individual faecal samples from randomly selected animals were taken and examined for the presence of nematode eggs, trematodes, cestodes and lung worms. In addition all selected small ruminants were clinically examined. Herd faecal samples were also examined for the presence of nematode eggs, trematodes, cestodes and lung worms. All faecal samples (individual and herd samples) were prepared by sedimentation/flotation, sedimentation and the Baermann examination. In addition to the qualitative analyse a quantitative analyse by McMaster counting technique with a detection limit of 50 eggs per gram of faeces (epg) was done. The whole laboratory procedure was performed according to the rules of the Standard Operating Procedure (SOP) of the Institute of Parasitology of the University of Veterinary Medicine, Vienna.

Furthermore, a faecal egg count reduction test was accomplished. Selected animals were randomly assigned to a treatment and control group. All animals were weighted and the small ruminants according to the treatment group were dewormed based on the determined weight. The control group was left untreated.

Results: Nematode infestation was detected in most of examined sheep and goats and also in all investigated herds. Protostrongylides were found in six flocks of sheep and in all flock of goats and the individual prevalence of Protostrongylides varies between about 10% and over 50%. The prevalence of *Dicrocoelium dendriticum* and *Fasciola hepatica* seem to be different between the various regions in Austria.

Correlations between some clinical parameters were detected for sheep and goats.

The effect of the used anthelmintic wasn't satisfactory in all herds and the egg count reduction and also the calculated lower confidence interval show a reduced effect of the used drug.

Conclusions: Endoparasite infestation is common in sheep and goats in Austria and there are variations between different Federal States of Austria with different climatic conditions. Anthelmintic resistance is an increasing problem and a high risk for small ruminants. The reduced efficacy of anthelmintic provides both, a medical and also an economic problem and should not be underestimated. So, it is very important to practice a well-considered and consequential anthelmintic management in cooperation with the farmer to minimize the problem of resistance.

P01-001-129

Evaluation of the impact of vaccination against staphylococcal mastitis in milk yield in assaf ewes in Spain.

Jesús Ángel Tamayo Ayarza ¹ Miguel Ángel Sanz Franco ² Teresa Calvo González-Valerio ² Virginia Tabera Escudero ¹

¹ADS Ovino de Campos , Palencia, ²Laboratorios HIPRA, Amer (Girona), Spain

Objectives: Staphylococci are the main pathogens responsible for mastitis in dairy sheep flocks. Implementation of a mastitis control program is an essential step in improving milk quality and disease prevention. One of the measures included in these control programs is vaccination. The objective of this study was to evaluate the impact of vaccinating against Staphylococcal mastitis (composed by a Staphylococcus aureus inactivated, expressing Biofilm strain.) on milk yield. The relationship between subclinical mastitis and milk yield is well described in the literature. Mastitis is strongly correlated with a decline in milk yield.

Materials and Methods: The study was performed in an intensively managed dairy sheep flock in the Palencia region (Spain) in which Coagulase-Negative Staphylococci-related subclinical mastitis was present (around 1 million bulk tank somatic cells per mL). Recorded clinical mastitis cases were below 1% per year. One hundred and eight sheep were randomly assigned to one of two groups: i) group V, which consisted of 47 animals that were vaccinated (VIMCO, Laboratorios Hipra, S.A.), according to the recommended administration program; and ii) group C which consisted of 61 animals that were not vaccinated. Management of both groups was the same.

This farm has individual milk yield measurement and total lactation milk yield estimation (Gerionte Oc.) based on monthly records. These data allowed proper monitoring of the daily milk yield (DMY), total lactation milk yield (LMY), and days in milk (DIM). Results were segmented into three categories depending on the lactation number: 1st to 3rd lactation (period A), 4th to 5th (period B) and 6th or more (period C).

Results: The vaccinated animals (group V) produced more milk (18.6%) in fewer days (12.9) than the non-vaccinated group (group C). In group V, results of DMY, LMY and DIM were 1.255 L, 273.38 L and 221 days, respectively, in period A, 1.166 L, 227.54 L and 190 days, respectively, in period B, and 0.946 L, 164.19 L and 169 days, respectively, in period C. In group C, values of DMY, LMY and DIM were: 1.182 L, 239.43 L and 210 days, respectively, in period A, 1.077 L, 176.85 L and 201 days, respectively, in period B, and 0.967 L, 195.29 L and 189 days, respectively, in period C. In the overall data DMY and LMY were higher (7.84% and 16.82, respectively) with an average DIM 12.9 days shorter. Animals with more than five lactations did not show any improvement with the vaccination which might be due to a chronic infection and lesions in the udder.

Conclusions: Subclinical Staphylococcal mastitis prevention through vaccination (VIMCO) can contribute to increase milk yield in sheep. In this case, there was a difference of milk production of 35 L per animal which may have a direct economic benefit of €30 (calculated using a milk price of €0.85/L) based on milk production alone.

First case of tick-borne encephalitis in sheep in Germany

Brigitte Böhm ¹ Benjamin Schade ¹ Benjamin Bauer ¹ Bernd Hoffmann ² Donata Hoffmann ² Martin Beer ² Christine Klaus ³ Herbert Weissenböck ⁴ Jens Böttcher ¹

¹Bavarian Animal Health Service, Poing, ²Institut of Virology , ³Institute of bacterial Zoonosis and infections, Friedrich-Loeffler-Institut, Isle of Riems, Germany, ⁴Institute of Pathology and Forensic Veterinary Medicine, University of Veterinary Medicine, Vienna, Austria

Objectives: Tick-borne encephalitis (TBE) is the most important viral tick borne zoonosis in Europe. In Germany, the highest incidence is reported from the federal states Bavaria and Baden-Württemberg with about 250 annual human cases. TBE is caused by the TBE virus (TBEV, Flaviviridae) which is transmitted by ticks, particularly Ixodes ricinus or alimentary by unpasteurized milk or milk products from viramic ruminants. In veterinary medicine only sporadic cases in dogs, horses, small ruminants and a monkey have been reported despite a high number of wild and domestic animals tested TBEV seropositive.

Materials and Methods: In May 2015, a five month old lamb from a farm with 15 Merino Land Sheeps and followers showed an impaired general health with pyrexia and acute neurological signs. The sheep suffered from a torticollis, tremor, nystagmus, salivation and finally somnolence with inappetence and immobility. The veterinarian suspected listeriosis. The animal was euthanized and submitted for pathological examination. Following necropsy, a histopathological, immunohistochemical, bacteriological, parasitological and virological analysis was performed. Additionally, sera of all sheeps and followers were examined serologically.

Results: At necropsy, the sheep showed a moderate to severe infestation with Trichostrongylus species, Eimeria species and Moniezia species. Histopathology revealed a mild to moderate, necrotizing, lymphohistiocytic and granulocytic meningoencephalitis with gliosis and neuronophagia. Immunohistochemistry for TBEV was negative. RNA of TBEV was detected in the brain by real-time RT-PCR and subsequent PCR product sequencing. A phylogenetic analysis revealed a close relationship to "Tick-borne encephalitis virus strain Kumlinge A52". TBEV could be cultured from brain tissue. Serologically, two of 21 blood samples were questionable positive for TEBV in an ELISA and one sample was positive in a serum-neutralization test.

Conclusions: To the authors knowledge this is the first report of a naturally TEBV infection in a sheep in Germany with clinical manifestation. TBEV infection should be considered as a differential diagnosis in a sheep with neurological signs.

Phimosis occurrence in lambs in a feedlot and their association to breeds

Rafaela S. Baptista ¹ Natália M. Rahal ¹ Fernanda Bovino ¹ Guilherme G. Alves ¹ Bianca Gerardi ¹ Flavia A. Lucas ¹ Juliana R. Peiro ¹ Lina Maria W. Gomide ¹ Francisco L. F. Feitosa ¹ Luiz Claudio Mendes ¹

¹Univ Estadual Paulista - Unesp - FMVA - Campus de Aracatuba, Aracatuba, Brazil

Objectives: The aim was to assess the presence of phimosis, congenital decreased of the preputial orifice diameter that impedes the protrusion of the penis, in a population of lambs in a feedlot and correlate with different breeds of sheep.

Materials and Methods: were used 200 sheep, from five different breeds or crosses (Dorper, Ile de France, Santa Inês, Suffolk and Texel) aged between two and three months old, with average weight of 31.04 ± 3.20 kg from a feedlot of the Teaching Veterinary Hospital of the FMV – Aracatuba campus of the Univ Estadual Paulista “Julio de Mesquita Filho”- Unesp. For evaluation, to verify the presence or not of phimosis, the animals were contained seated and performed the exhibition of the penis. Data were noted in tables (presence or absence of phimosis) and then statistically analyzed using the GraphPad Stat program v 3.10. Fisher’s exact test was used to verify the association between presence/absence of phimosis and breed. The presence of phimosis was dependent on the breed of the evaluated animals ($p < 0.0005$).

Results: From the 200 evaluated sheep, 48 (24.00%) had phimosis and five (2.50%) had urethral obstruction. The presence of phimosis is related to the Ile de France breed because of the 36 animals of this breed, 16 had phimosis (44.44%). Of the 38 Santa Inês animals evaluated, seven (18.42%) had phimosis. Among the 74 animals of the Suffolk breed analyzed, 22 (29.73%) had phimosis. Of the 37 Dorper animals evaluated, three (8.11%) had phimosis. None of the 15 animals of Texel assessed presented phimosis.

Conclusions: We conclude that the Ile de France breed is more predisposed to phimosis and that the high incidence of phimosis observed in feedlot, draws attention to the importance of evaluating the penis, especially in those destined for reproduction, since the presence of this condition impairs reproductive function.

Pulmonary cryptococcoma with encephalitic dissemination in a goat from Midwestern Brazil

Selwyn A. Headley^{1,2}, Luciano A. Pimentel², Lucienne G. Pretto-Giordano¹, Hugo S. Toma², Alexandre M. Amude², Marcelo D. Santos², Priscila F. M. L. Gomes², Lázaro M. Camargo², Letícia S. V. Souza², Amauri A. Alfieri¹, Mark Krockenberger³

¹Department of Veterinary Preventive Medicine, Universidade Estadual de Londrina, Londrina, ²School of Veterinary Medicine, Universidade de Cuiabá, Cuiabá, Brazil, ³Department of Veterinary Pathology, Faculty of Veterinary Science, University of Sydney, Sydney, Australia

Objectives: Cryptococcosis is a mycotic disease of humans and domestic animals that is caused by the *Cryptococcus neoformans* complex of organisms, includes into two distinct species: *C. neoformans* and *C. gattii*. Most descriptions of cryptococcosis in domestic animals have occurred in dogs and cats, with few cases in other species. The objective of this study was to describe the pathological and immunohistochemical findings associated with pulmonary cryptococcosis with encephalitic dissemination in a goat.

Materials and Methods: A 3-year-old, mixed breed, female goat with clinical manifestations of progressive behavioural changes and disequilibrium was admitted at the Veterinary Teaching Hospital, Universidade de Cuiabá, Midwestern Brazil. This goat was maintained on a small farm that contained 16 goats reared on a semi-intensive system, where pigeons are frequently observed and ingest part of the

feed provided to goats. A samples of the cerebrospinal fluid (CSF) was collected for cytological evaluation. The clinical manifestations progressed and the animal died spontaneously despite adequate therapy. A necropsy was done soon after death and selected tissues were routinely processed for routine histopathological evaluation with the Hematoxylin and Eosin (H&E) method. Duplicate sections of the brain were stained by the mucicarmine histochemical method, and for the immunohistochemical (IHC) typing of the cryptococcal species by using monoclonal antibodies (mAb471, mAb302, and mAbF10F5) to stain the cryptococcal capsule. In addition, formalin fixed paraffin embedded (FFPE) tissue fragments of the brain were used in a fungal PCR designed to amplify the Internal Transcribed Spacers (ITS) regions I and II.

Results: Cytological evaluation of the centrifuged CSF revealed fungal organisms with morphology consistent with *Cryptococcus* sp. Grossly, a large space occupying gelatinous mass was observed at the left caudal pulmonary lobe, and several similar smaller masses at the frontal and temporal cortex, the thalamus, hippocampus and mesencephalon. The H&E evaluation of the pulmonary mass revealed large quantities of fine-budding, negatively stained thick-walled fungal organisms loose within the lung or within the cytoplasm of macrophages and a discrete influx of inflammatory cells; a distinct granulomatous reaction was not observed. Similar histopathological findings were observed within the intracerebral masses. The mucicarmine stain clearly imparted a pinkish coloration to the fungal organisms and the negatively stained thick-wall observed by H&E within the masses of the lung and the brain. Additionally, the mAb471 antibody positively labelled the capsule of all organisms within the *Cryptococcus neoformans* complex; the mAb302 antibody imparted a positive immunoreaction to the capsule of *C. neoformans* var. *grubii* and *C. neoformans* var. *neoformans* organisms; while the mAbF10F5 antibody positively labelled the capsules of *C. neoformans* var. *grubii* and *C. gattii* organisms. The interpretation of these IHC findings indicated that the intralesional thick-walled, fine-budding mycotic organisms observed by the H&E and the mucicarmine stains correspond to *C. neoformans* var. *grubii*. However, fungal DNA was not amplified from the FFPE tissues sections during the ITS PCR assays.

Conclusions: The fungal organisms observed by cytological and histopathological within the lungs and several areas of the brain are consistent with *Cryptococcus* spp., while the gelatinous masses in these organs are typical of cryptococcal granulomas (cryptococcomas). Further, the mucicarmine stain identified the intralesional fungal organisms as *Cryptococcus neoformans*, while IHC typing characterized the organisms as *C. neoformans* var. *grubii*, being diagnostic for cryptococcal organisms. Although the exact method of infection is unknown, it’s rather likely that the disease first affected the lungs with subsequent encephalitic dissemination.

Virulence factors of coagulase-negative Staphylococci isolated from sheep with subclinical mastitis and their relationships with cure rates

Luiz F. Zafalon¹, Lucas E. Pilon², Raul C. M. Santana¹, Maria L. R. S. Cunha³

¹Embrapa Southeast Livestock, Brazilian Agricultural Research Corporation, São Carlos, ²Doctoral Student of Veterinary Medicine, Universidade Estadual Paulista, Jaboticabal, ³Institute of Biosciences, Universidade Estadual Paulista, Botucatu, Brazil

Objectives: The objectives of the present study were to identify the species of Coagulase-negative Staphylococci in milk of mastitic ewes with and without antimicrobial treatment, and to investigate the presence of genes relating to resistance of β -lactam antimicrobials, formation of biofilms, production of enterotoxins and production of the toxic shock syndrome toxin.

Materials and Methods: Sixty sheep were divided into three groups: G1, without treatment; G2, animals treated via the intramammary route with 100 mg of cloxacillin during drying off; and G3, sheep treated via the intramammary route with 50 mg of nanoparticulate cloxacillin. Milk samples were gathered during drying off and 15 and 30 days after the parturition of the subsequent lactation. The analyses to identify the species of Coagulase-negative Staphylococci were carried out by means of the internal transcribe spacer technique and the investigation of the genes responsible for the virulence factors and resistance to oxacillin was performed using the polymerase chain reaction (PCR) technique. To determine the relationship between the variables was carried out the multiple correspondence analysis.

Results: *Staphylococcus warneri* was the most prevalent microorganism. No sample was positive for the *mecA* gene. The only gene relating to production of enterotoxins was *sec*. Among the genes relating to production of biofilm, *icaD* was the only one identified in the three experimental groups. Six untreated sheep present *S. warneri* with virulence factor genes before weaning. All of them continued to present subclinical mastitis during the subsequent lactation. Two untreated sheep with *S. epidermidis* isolation before weaning did not present spontaneous recovery 15 and 30 days after parturition. One of these presented microorganisms with the *icaD* gene, while the other concomitantly presented the genes *icaC* and *icaD*. In G2, mammary halves infected by *S. simulans*, which presented the *icaD* gene, and by *S. epidermidis*, which carried the *sec* gene, did not attain a cure after treatment for subclinical mastitis. Three sheep presented reinfection 30 days after parturition, after being treated with 100 mg of cloxacillin-benzathine (G2). Out of these, one presented *S. warneri* carrying the gene *icaD*, another presented *S. xylosum* carrying the gene *bap* and the third presented *S. chromogenes* with no occurrence of virulence factors during the pretreatment period. In G3, the cases of lack of cure by 15 and 30 days after parturition occurred in mammary halves infected by *S. epidermidis*, *S. warneri* and *S. simulans*. The gene *icaC* was observed during the pretreatment period among sheep infected by *S. epidermidis*, while the gene *icaD* was observed among animals infected by *S. warneri* and *S. simulans*.

Conclusions: The defense mechanisms of the mammary gland and the treatment for subclinical mastitis during the drying off period did not eliminate all species of CNS after parturition. Coagulase-negative Staphylococci that carries genes responsible for production of enterotoxins and biofilms can negatively interfere in the cure rates for mastitis among sheep.

Comments: The present study was conducted with the financial support from the São Paulo Research Foundation (FAPESP) (Process No. 2012 / 23044-0).

P01-001-134

Footrot Characterization in Serra Da Estrela Native Flocks

Rita Cruz^{1,2,3} Andreia Machado¹ Carmen Nobrega¹ João R. Mesquita¹ Helena Vala¹ Fernando Esteves^{1,2,3,*}

¹Agrarian Superior School, Polytechnic Institute of Viseu, VISEU,

²Clinica Veterinária Dão, SERRAVET, Nelas, ³Departamento Sanidade Animal, ANCOSE, Oliveira Hospital, Portugal

Objectives: Serra da Estrela native (SEN) breed of sheep is one of the most important in Portugal, standing responsible for the production of one of the most internationally recognized cheeses in the world, “Queijo Serra da Estrela” (protected designation of origin). One of the major risks to the sustainability of SEN dairy flocks is footrot, an infectious disease that causes lameness, decrease in milk production, weight loss and decrease in fertility. The aim of this work was to determine which parameters become decisive for the appearance of footrot in SEN dairy flocks, while establishing associations with environmental and nutritional variables.

Materials and Methods: The present study was carried out by performing an especially designed 27 multiple choice questionnaire, based on the underlying causes of lameness in livestock and in the clinical diagnosis performed by the vet technician of the clinical cases evaluated at the moment of the inquiry. The survey was performed during the execution of the official veterinary health program between February and September of 2014 by a veterinarian team from the Association of SEN Sheep Breeders (ANCOSE). The ovine producers (N=30, with a total of 1270 animals) were randomly selected from the extensive area of production of “Queijo Serra da Estrela”. The parameters evaluated in the study were: season and consequent weather changes during the period of the study, floor types, hygiene conditions, bed types, the existence and use of footbaths, location of footbaths, foot trimming and foot hygiene procedures. After the construction of the database and using the Statistical Package for Social Sciences version 16.0 the frequency response for each item was calculated.

Results: All SEN livestock producers are proactive in the treatment of lameness (70%). About 99.7% of lameness was related with footrot and most appeared in winter (36.7%). In some occasions there was not a specific season distribution (56.7% rainiest years). From the analyzed farms, 70% use straw as a floor bed, followed by bush (21%). 45.6% of animals were clinically diagnosed with footrot and were sheltered in straw floor. Bed quality is good in 40%, however frequent changes in the floor bed in the preceding 15 days had a higher rate of footrot diagnosed cases (33,23%) compared to monthly changes. Regarding sheepfold animal number, the distribution is proper in 36.7%, elevated in 30%, overcrowded in 6.7% and low in 23.3%. Clinically ill diagnosed animals in last category were the lowest observed (3%). Concerning hoof trimming, 76.7% trims while 23.3% reported not to perform that task. From those that perform trimming, 73.9% do it only when necessary, 21.7% at the time of clipping and 4.4% when the animal is affected. One curious result was that animals who perform trimming at clipping had higher footrot cases (52.6%), unlike those who trim only when necessary (40.2%) or even when animals are clinically ill (0.91%). Mostly all in the presence of footrot choose a local treatment (95.2%) using antibiotic sprays, instead of parenteral antibiotic treatment. Footbath is rarely used in the prevention (13.3%) of this disease and when it is misconceived (25%) and incorrectly formulated (100%).

Conclusions: This study was the first performed in Portugal focusing footrot characterization in native SEN flocks. Economic impact in SEN dairy flocks is attributed to factors such as direct decrease in milk and meat production, early slaughter of affected animals due to non responsive treatment and medical expenses. The most effective eradication method combines first of all the ability to understand the problems of SEN producers and implementation of preventive measures and treatment of footrot. Often linked to lack of formation, the advance age of portuguese producers the mentality and social factors block the advance of veterinarian intervention itself.

P01-001-135

Heat tolerance environmental indices for Brazilian hair sheep

Luiza Seixas¹Cristiano B. de Melo¹Adriana M. Menezes¹Alexandre F. Ramos²Candice B. Tanure¹Vanessa Peripolli¹Paulo Ricardo M. Lima¹Concepta McManus^{1,*}

¹University of Brasilia, ²Embrapa Genetic Resources and Biotechnology, Brasilia, Brazil

Objectives: The aim of the present study was to analyze if four commonly used heat tolerance and seven environmental indices are appropriate to evaluate heat stress in Santa Ines and Morada Nova sheep and if the limits used to classify thermal stress are suitable for these breeds.

Materials and Methods: The experiment was repeated six times at the beginning of winter period in Brasilia, Brazil. Twenty-six sheep from two genetic groups were used and data were collected twice a day, with a total of 156 observations.

Thermographic photos and physiological parameters such as respiratory rate, heart rate and rectal temperature were collected in the morning and afternoon.

Physical variables included: shoulder height, thoracic perimeter, back and body lengths, rump height, rump width, breast width, skin thickness, number of hairs, hair length, skin and coat color.

The following heat tolerance test based on animal measures were calculated: Iberia, Benezra test, Rauschenbach-Yerokhin (RY) and Baccari.

The environment was characterized using the following measurements: Black globe temperature (TBG), dry bulb temperature (TDB), relative humidity (RH), wet bulb temperature (TWB) and dew point (Td). Based on these data, the following indices were calculated: Temperature and Humidity Indices (THI): $THI1 = (0.55 \times TDB + 0.2 \times Td) \times 1.8 + 32 + 17.5$; $THI2 = [0.4 \times (TDB + TWB)] \times 1.8 + 32 + 15$; $THI3 = (0.8 \times TDB) + [(RH/100) \times (TDB - 14.4)] + 46.4$; $THI4 = TDB + (0.36 \times TDB) + 41.2$; $THI5 = (1.8 \times TDB + 32) - [(0.55 - 0.0055 \times RH) \times (1.8 \times TDB - 26.8)]$; $THI6 = (TDB + TWB) \times 0.72 + 40.6$; Black Globe-Humidity Index (BGHI) = $TBG + 0.36Td + 41.5$;

Statistical analysis was performed using SAS version 9.3 (Statistical Analysis Institute, Cary, North Carolina). The procedures used included correlations and "Broken-Line" regressions.

Results: High daily air temperature variation (14.6 - 43.2°C) was seen during the experiment with high average temperature and low relative humidity (13%) in the afternoon. High environmental indices (THI2: 85.31) were also observed in the afternoon, reaching values classified as danger (THI: 79-83) and emergency (THI ≥84).

Correlations between environmental and physiological parameters were positive, with higher correlation between rectal temperature and THI3 (0.71). Regarding heat tolerance indices, rectal temperature was negatively correlated with Iberia index (-0.44) and positively with the others. The Benezra coefficient was the only one to correlate significantly with all the physiological parameters, showing perfect correlation with respiratory rate (1.00). A negative correlation was observed between the Iberia index and the morphometric measures and positive correlation between these measures and rectal temperature, Benezra, Bacarri and RY heat tolerance indices.

In general, correlations between surface temperature and environmental indices were high and positive, with higher correlations between the temperature of the neck and THI3 and THI5 (0.89).

Regarding heat tolerance indices, the Benezra was the best correlated with surface temperatures with correlation of 0.52 between this index and foot temperature.

The environmental indices were best related with the temperature of the neck and foot. The inflexion points between the rectal temperatures and environmental indices varied according to the equation used, with higher values for the THI1 (95.55) and THI2 (81.32).

Conclusions: The high correlation between environmental indices and rectal and skin temperatures demonstrates that these indices are good tools to evaluate thermal comfort of sheep. However, in order to classify these appropriately the equation used needs to be carefully studied, because these classifying values can vary according to the species and equation. Regarding the heat tolerance tests, Iberia and Benezra indices were best correlated with the parameters studied.

Heat tolerance in Brazilian Santa Ines and Morada Nova hair sheep

Luiza Seixas¹Cristiano B. de Melo¹Adriana M. Menezes¹Alexandre F. Ramos²Candice B. Tanure¹Vanessa Peripolli¹Paulo Ricardo M. Lima¹Giane Paludo¹Concepta McManus^{1,*}

¹University of Brasilia, ²Embrapa Genetic Resources and Biotechnology, Brasilia, Brazil

Objectives: The aim of the present research was to evaluate heat tolerance using heat tolerance environmental indices, physiological, physical, and hematological parameters in Santa Ines and Morada Nova sheep in Brazil.

Materials and Methods: The experiment was repeated six times at the beginning of winter period in Brasilia, Brazil. Twenty-six sheep from two genetic groups (Morada Nova (MN) and Santa Ines (SI)) were used and data were collected twice a day, with a total of 156 observations.

Physiological and hematological parameters such as respiratory rate (RR), heart rate (HR), rectal temperature (RT), number of erythrocytes (RBC), leukocytes (WBC), platelets (PLAT), concentration of hemoglobin (HB), Mean Corpuscular Volume (MCV), Mean Corpuscular Hemoglobin (MCH), Mean Corpuscular Hemoglobin Concentration (MCHC) Packed Cell Volume (PCV), total plasma proteins (TPP), plasma fibrinogen (FIBR) and thermographic photos were collected on three days in both morning and afternoon.

Physical variables included: shoulder height (SH), thoracic perimeter (TP), back (BKL) and body (BL) lengths, rump height (RH), rump width (RW), breast width (BW), skin thickness (ST), number of hairs (NH), hair length (HL), skin and coat color.

The following heat tolerance tests based on animal measures were calculated: Iberia and Benezra. The environment was characterized using the following measurements: dry bulb temperature (TDB) and relative humidity (RH). Based on these data, the following indices were calculated: $THI = (0.8 \times TDB) + [(RH/100) \times (TDB - 14.4)] + 46.4$; Statistical analysis was performed using SAS version 9.3. The procedures used included analysis of variance, correlation and principal component analysis. Means were compared using adjust Tukey test with a significance level of 5% ($p < 0.05$).

Results: High daily air temperature variation (14.6 - 43.2°C) was seen

during the experiment with high average temperature and low relative humidity (13%) in the afternoon. THI reached values classified as danger (THI: 79-83) and emergency (THI \geq 84) in the afternoon.

The RT, RR, thermograph temperatures and the Benezra index were higher during the afternoon and most blood parameters were lower in this period. Santa Ines animals were larger and had longer, greater number and darker hair, thicker skin, higher RR, TPP, HB, MCHC, WBC, Benezra index and lower Iberia index.

RT was negatively correlated with skin brightness. Regarding heat tolerance indices, size measurements, skin and hair brightness were negatively correlated with Benezra. Surface temperatures were positively correlated with RT, RR and Benezra index, with highest correlations with RT. Regarding blood parameters, a direct relationship was noted between heart rate, number of red blood cells and hemoglobin concentration and negative correlation between these blood parameters and Iberia index and THI.

The principal component analysis showed that 47% of the variation was explained by physiological and physical variables of the animals. High rectal temperature, larger animals and thicker skin were related with higher Benezra and lower Iberia index. Regarding surface temperatures, 56% of the variation was explained by the characteristics studied. It was noted a direct relation between these temperatures, physiological components, THI and Benezra index and indirect with Iberia index.

Conclusions: The environmental index indicated that sheep suffered heat stress during the afternoon, but due to the good adaptation of MN and SI breeds, these animals were able to maintain their physiological and blood parameters within reference values. Although both breeds can be considered adapted to the environmental conditions, MN breed may be more suitable for farming in the Midwest region because of its physical characteristics which favors heat tolerance.

Electroencephalography for assessing pain and analgesia in sheep

Charissa Harris¹, Peter White¹, Sabrina Lomax¹

¹Veterinary Faculty , University of Sydney, Sydney, Australia

Objectives: Numerous painful husbandry procedures are performed routinely within the Australian sheep industry. The assessment of analgesia is limited by current pain detection methods such as behaviour and observation. The use of electroencephalography (EEG) in relation to therapeutic efficacy is used in human medicine (pharmacology-EEG), and offers potential as an effective and practical way of measuring pain response and efficacy of analgesia in livestock. The aim of this study was to evaluate the electroencephalographic response of conscious sheep with and without the administration of the non-analgesic sedative midazolam.

Materials and Methods: The EEG responses for two ewes and two wethers (n=4) were recorded prior to and post administration of midazolam for a minimum of 5 minutes. Raw data was band-passed filtered offline between 0.1-40Hz and visually inspected with traces containing significant movement artifacts discarded. The maximum power frequency (f_{PM}) was calculated using LabChart Version 7 software (AD Instruments) and analysed using restricted maximal likelihood regression (REML) for linear mixed models analysis in Genstat (V16). Effect of sheep and time (pre and post administration of midazolam) were assessed in the model.

Results: There was a significant effect of sheep on f_{PM} ($P < 0.001$). The two ewes (Sheep 1 and 2) had higher mean f_{PM} (22.5 ± 0.013 and 6.95 ± 0.008 Hz respectively) than the two wethers (Sheep 3 and 4, 0.773 ± 0.015 and 0.764 ± 0.015 Hz respectively). This suggests there may be an effect of sex on f_{PM} , further analysis using larger sample sizes is required. There was a significant effect of time on f_{PM} ($p < 0.001$). There was a significant reduction in f_{PM} following administration of midazolam in all sheep. Mean f_{PM} was $9.052 (\pm 0.009)$ Hz before and $6.439 (\pm 0.01)$ Hz after midazolam administration. These results indicate a reduction in movement artifact following non-analgesic sedation, however further work is needed to compare the effects of pain and analgesia on f_{PM} .

Conclusions: Results indicate a significant effect of sedation on the maximum power frequency of the EEG output. A decrease in mean f_{PM} suggests a reduction in movement artifact, allowing for more accurate EEG analysis of perceived pain in conscious sheep. Effects of sex need to be further explored using larger sample sizes. The use of non-analgesic sedation will allow for animals to remain conscious, reducing costs and eliminating impracticality elements of complete sedation. Use of pharmacologyEEG methods in sheep will allow for practical on-farm assessment for analgesic interventions for painful husbandry procedures.

Amilorating Effects Of Cysteine, Glutathione And Taurine During Freezability Of Ram Spermatozoa

Youssef Elseady¹, Ayate Abdelmaksoud mahmoud², faheim ELbahey¹, Mona shaker²

¹department of physiology, faculty of veterinary medicine , Mansoura University, Mansoura , Egypt, Mansoura, ²animal reproduction research institute, agriculture research center, cairo , Egypt

Objectives: Ram sperm have a higher ratio of polyunsaturated/ saturated fatty acids and a lower ratio of cholesterol/phospholipids molar than other species, which renders the sperm much more vulnerable to oxidative damage caused by reactive oxygen species (ROS) .The aim of the current study was to evaluate the effects of cysteine, glutathione and taurine on the freezability of ram spermatozoa and biochemical parameters

Materials and Methods: Semen samples from ten mature mixed Barki rams were used in this study. Pooled semen samples were divided randomly into 7 aliquots one was diluted with a Shotor extender as a control basal diluent while others in addition to basal extender L-Cysteine, L- reduced glutathione and taurine were added by two levels for each to present seven experimental groups. Diluted semen cooled to 5°C then frozen by liquid nitrogen in 0.25 ml French straws. After 48 hr frozen, straws were then thawed individually at 37 °C for 30 sec. in a water bath then subjected to evaluation.

Results: The obtained results showed that, addition of glutathione by a rate of 5mM was significantly increases motility than control group. Similarly, addition of taurine by a rate of 50mM significantly increased the viability index of cryopreserved semen samples.

Percentages of acrosomal defects were dramatically decreased ($P < 0.05$) with glutathione (10 mM) addition compared to control (9.00 \pm 1.16 % and 21.00 \pm 0.58 % respectively).

In regards to sperm membrane integrity, cysteine (5 mM) provided a greater protective effect (47.00 \pm 1.16) compared to control (% , 35.33 \pm 0.88 %).

Antioxidant addition showed decreased enzyme leakage and significantly ($P < 0.05$) improved total antioxidant capacity (TAC) especially taurine (50Mm) compared to control group.

In regards to DNA integrity, taurine (50mM) provided a significant protective effect (98.51 ± 0.42 %) compared to control.

Conclusions: Findings of this study showed that addition of cysteine, glutathione and taurine to semen extenders, of greater benefit to quality of frozen-thawed ram sperm. However further investigation on their effect on fertilizing capacity and pregnancy rate still needed.

Sexual behaviour, semen quality and testosterone levels in Saint Croix hair sheep breed rams under extensive pasture scheme in a semi-desert region

Adan G. Gómez¹Hugo B. Barragán²Jose Fernando V. Armijo³Rogelio Alejandro L. Torres⁴Alejandro Sergio D. B. González⁵Juraj Grizelj⁶Carlos L. Palomera⁷Fernando S. Dávila^{8,*}

¹Laboratory of animal reproduction, ²Faculty of Agronomy, Faculty of Agronomy, University Autonomous of Nuevo León, Marín, N.L., ³University Centre Temascaltepec, Autonomous University of State of Mexico, Estado de Mexico, ⁴Faculty of Veterinary Medicine and Zootechnics, Mexico, ⁵University Autonomous of Nuevo Leon, ⁶Faculty of Agronomy, University Autonomous of Nuevo León, Escobedo, N.L., Mexico, ⁷Faculty of Medicine veterinary, University of Zagreb, Zagreb, Croatia, ⁸Academic Division of Animal Sciences, University Juarez Autonomus of Tabasco, Villahermosa Tabasco, ⁸Laboratory of animal reproduction, University Autonomous of Nuevo León, Marín, N.L., Mexico

Objectives: the objective of this research was to evaluate semen quality, sexual behavior traits and testosterone levels during the year and the influence of feed supplementation in Saint Croix breed adult rams under semi-desert climate conditions in Northeast Mexico

Materials and Methods: This research was conducted at the Laboratory for Animal Reproduction of Marín Academic Unit, Faculty of Agriculture, Autonomous University of Nuevo Leon, which is located in Marín, NL, Mexico. Its geographic coordinates are $25^{\circ} 54'$ north latitude and $99^{\circ} 58'$ west longitude, at an altitude of 451 meters. Temperatures range from $18-43^{\circ}\text{C}$ in summer and 10 to -2°C in the winter time. The average annual temperature is 23.1°C with an average annual rainfall of 429 mm (INIFAP, 2009). Sixteen adult rams were used, randomly divided into grazing group (GG) and supplemented group (SG). Each group consisted of 8 rams that grazed on buffel grass pasture; rams from SG were additionally supplemented with a concentrate of 14 % crude protein and 2.5 Mcal of metabolizable energy (1kg/animal/day). Every two weeks, semen was collected by artificial vagina, sexual behavior traits were evaluated and sera were taken to determine testosterone levels. The statistical analysis of variance was made using SPSS (SPSS, version 19, 2008) statistical package with linear model, where supplementation and month of evaluation were used as independent variables. When significant difference was found, the comparison of means by the minimal significant difference was performed.

Results: In general, SG males had better body condition score and showed higher live weight gain ($P < 0.05$) than the GG rams. However, regarding scrotal circumference, statistical difference was found only in the month of evaluation ($P < 0.05$). For semen quality traits, statistical

difference was observed ($P < 0.05$) in the month of evaluation with respect to the SG. The values of some semen quality traits were higher or equal in the GG than in the SG, especially during the rainy periods (from April to May and from August to October). Concerning the sexual behavior traits, statistical difference of feed supplementation and month of the year was found ($P < 0.05$) on reaction time, sniffing and flehmen trait values, with the highest values recorded in the SG from March to May. Furthermore, a statistical difference was found ($P < 0.05$) in both the month of evaluation and supplementation on every feature of the sexual behavior.

Regarding testosterone levels, the SG had statistically significant interaction in the month of evaluation ($P < 0.05$), with the highest values being recorded in June (summer time) and October (autumn term) and the GG had the lowest in spring season (March-May) compared to the SG.

Conclusions: It is concluded that rams of Saint Croix breeds are able to adapt to adverse environmental and nutrition conditions in semi-desert climates and can be used to induce heat and mate the ewes in any reproductive season. However, with good mating and nutrition management, improved sexual behavior, semen quality parameters, and testosterone levels are achieved which improves the reproductive efficiency of the herds extensively raised in those regions at global level.

Comments: It is a work that took place in northeastern Mexico in a hair sheep breed adapted to semi-desert regions.

Teat-End Hyperkeratosis In Dairy Ewes And Its Predisposing Factors

Sotiria Vouraki^{1,1}Sofia-Afroditi Termatzidou¹Panagiota Kazana¹Athanasios I. Gelasakis¹Markos Managos¹Georgios E. Valergakis¹Georgios Arsenos¹

¹Laboratory of Animal Husbandry, School of Veterinary Medicine, Faculty of Health Sciences, Aristotle University of Thessaloniki, Thessaloniki, Greece

Objectives: Although teat-end hyperkeratosis is a condition well known and described in dairy cows, relative information is scarce in dairy ewes. The objective of the present study was to assess teat-end hyperkeratosis in dairy ewes raised under Mediterranean conditions.

Materials and Methods: A random sample of 28 dairy sheep flocks was used. The average flock comprised 229 ± 146.0 milking ewes with an average milk yield of $ca\ 273 \pm 71.7$ kg/lactation period. All flocks were visited by the same veterinarians that assessed milking procedure using a designated recording sheet. Records included use of gloves by milkers, pre-stripping, clusters removal after vacuum cessation and post-milking disinfection. Technical characteristics of the milking parlour and relative equipment were also assessed in terms of their functionality and general condition. A designated equipment (Exendis Milking System Analyser, PTV) was used to measure vacuum level at teat-end, pulsation rate and pulsation ratio in 3 randomly selected milking units of the milking parlour. The vacuum level in the vacuum pump was also recorded; the difference of vacuum level between clusters and vacuum pump was calculated. In each flock, a random sample of 20% of the milking ewes was subjected to a detailed teat-end examination for the assessment of hyperkeratosis using the 4-scale evaluation method described by Mein et al. (2001). Evaluation was performed immediately after cluster removal. The problem was considered serious when scores 3+4 and/

or 4 were above 20% and 10%, respectively. Data were analysed using univariate analysis of variance with SPSS 22, statistical software. Vacuum level, difference of vacuum level between clusters and vacuum pump, pulsation rate, pulsation ratio and clusters removal after vacuum cessation were transformed into categorical variables and used as fixed effects.

Results: Average prevalence (%) of hyperkeratosis score 1, 2, 3 and 4, at teat-level, was 69.3, 15.5, 9.9 and 5.2, respectively. The analyses at flock level showed that 39% of the flocks (11/28) had a serious problem of teat-end hyperkeratosis. In five out of the 11 flocks scores 3+4 were assigned to 30.2% of teat-ends; from them in 14.5% of cases the hyperkeratosis score was equal to 4. The other 5 flocks had scores 3+4 assigned to 23.9%, whereas in one flock, score 4 was assigned to 12.5% of teat-ends. The effect of vacuum level on teat-end hyperkeratosis was significant ($P < 0.05$). In flocks where the vacuum level of the milking parlour was >40 kPa a significantly ($P < 0.05$) higher percentage of teat-ends scored 3+4 was found. The effects of other factors assessed were not significant ($P > 0.05$).

Conclusions: A high prevalence of teat-end hyperkeratosis in dairy ewes was observed; nearly 40% of the examined flocks had a serious problem. In most cases, the higher percentage of teat-ends scored 3+4 was observed in flocks milked with higher vacuum level. The latter suggested that teat-end hyperkeratosis in dairy ewes may be closely related to the functionality and the general conditions of the milking parlour.

Clinical cases in sheep and goat attended by the GEPECO from Universidade Federal Fluminense at Rio de Janeiro State, Brazil

Mario Balaro¹ Ana Clara S. Ribeiro¹ Alex S. Santos¹ Luiza M. Cavalcanti¹ Loara Helena S. Gonçalves¹ Claudia Del Fava² Edviges M. Pituco³ Alessandra Figueiredo C. Nassar⁴ Simone Miyashiro⁴ Paulo Cesar A. R. Silva¹ Felipe Z. Brandão¹

¹Clinical and Animal Pathology, Universidade Federal Fluminense, Niteroi, ²Animal Pathology lab, ³Laboratory of Animal Virology,

⁴Laboratory of Bacteriology, Instituto Biológico, São Paulo, Brazil

Objectives: The main goal is to report clinical cases in sheep and goats attended by the Group of Study, Research and Extension in Goats and Sheep (GEPECO) from Faculty of Veterinary at Universidade Federal Fluminense in Rio de Janeiro State in partnership with animal diagnostic laboratories of the Instituto Biológico in Sao Paulo.

Materials and Methods: A retrospective study was carried out from October 2012 to October 2015 at Rio de Janeiro State. A total of eight farms of meat sheep, seven of dairy goats, two of meat goats and one of dairy sheep were encompassed. Clinical data were collected from the field routine of the GEPECO with local sheep and goat farmers. For microbiological and histopathological diagnosis of some illness, biological material was collected from sick or necropsied animals and sent to laboratories of virology, bacteriology and pathology of the

Instituto Biológico in Sao Paulo.

Results: A total of 733 clinical cases were attended and separated by: infectious(333/733), parasitic(206/733), reproductive(113/733), metabolic (34/733) and traumatic cases (47/733). Infectious cases: contagious ecthyma (54/333), dermatophilosis (48/333), caseous lymphadenitis (47/333), keratoconjunctivitis (42/333), scours (30/333) pneumonia (29/333), bluetongue (24/333), mastitis (21/333), enterotoxemia (9/333), caprine arthritis encephalitis (14/333), papillomatosis (8/333), foot rot (5/333) and tetanus (2/333). Parasitic diseases: hemoncosis (53/206), eimeriosis (41/206), monieziosis (38/206), cutaneous myiasis (33/206), oesophagostomosis (25/206), visceral cysticercosis (7/206), pediculosis (6/206), babesiosis and anaplasmosis (3/206). Reproductive findings: hydrometra (53/113), abortions (10/113), cystic endometrial hyperplasia (9/113), follicular cyst (9/113), pyometra (5/113), macerated fetus (4/113), birth defects (4/113), mucometra (3/113), luteal cyst (2/113), retained placenta (3/113), mummified fetus (2/113), uterine prolapse (2/113), polycystic ovary (1/113), cervicitis (1/113), monorchidia (2/113), testicular hypoplasia (1/113), testicular degeneration (1/113) and anorchidia (1/113). Metabolic cases: photosensitization (12/36), seasonal dermatitis (11/36), pregnancy toxemia (9/36) and abomasal ulcers (3/36). Traumatic cases: dog bite (11/47), corneal ulcers (10/47), locomotor system injuries (8/47), abdominal hernia (6/47), ear hematoma (3/47), fracture of long (3/47), cervical (2/47) and sacral bone (1/47), laceration of ear (2/47) and udder (1/47).

Conclusions: The animal health management in small ruminants, compared to cattle, is still scarce by handlers, farmers and field veterinarians. It is highlights the importance of the continuous promotion of health education for people involved with the sheep and goat care in Rio de Janeiro State.

Comments: The authors believe the data contained in this abstract are relevant because its expose to the international scientific community about the diseases found in small ruminants in the southeastern Brazil. Furthermore, these findings may assist in the discussion of the local sanitary control measures.

Case of study: Evaluation of the impact of mastitis vaccination on mastitis treatment in a dairy goat farm in the south-west of Spain

Rosa Ana Sánchez Botella¹ Miguel Ángel Sanz Franco² Teresa Calvo González-Valerio² José Antonio Martínez García¹

¹ALIMER S. COOP., Lorca (Murcia), ²Laboratorios Hipra, Amer (Girona), Spain

Objectives: Staphylococci are the main pathogens responsible for mastitis in dairy goat herds. Implementation of a mastitis control program is an essential step in improving milk quality and preventing infection. One of the measures that can be included in these control programs is vaccination. The objective of this field trial was to evaluate the efficacy of vaccination for Staphylococcal mastitis in reducing mastitis treatments in a commercial dairy goat farm.

Materials and Methods: The study was performed in a dairy goat farm (Murciano-Granadina) in the southwest Spain where goats were vaccinated with a commercially available Staphylococcal mastitis vaccine (Vimco, Laboratorios Hipra S.A.). The farm has 550 goats and 5 kidding periods (February, April, June, September and November).

The main mastitis pathogen described is *Staphylococcus* (CNS and *S. aureus*). The vaccination program started in August 2014 and was implemented according to the recommended administration schedule. The study compared mastitis treatments before (monthly average of 2 years) and after (1 year) the first immunization of the herd. No changes other than vaccination occurred during this time. Two different mastitis treatments, which were recorded monthly, were used: (A) antibiotic and nonsteroidal anti-inflammatory drugs (NSAIDs) for severe mastitis and (B) nonsteroidal anti-inflammatory drugs for mild mastitis. Total treatment (A+B) was also calculated.

Results: The number of mastitis treatments per year before vaccination was 88 in group A, 50 in group B, and 138 in the A+B groups combined. After vaccination the number of treatments recorded was 61 in Group A, 5 in Group B and 65 in Groups A+B. Overall, fewer mastitis treatments (A, B and A+B) were required after starting vaccination than before (-31%, -90% and -52%, respectively). The total reduction in treatments (A+B) from before to after vaccination program was introduced as follows: September (-25%), October (-44%), November (-92%), December (-40%), January (-24%), February (-85%), March (-33%), April (-20%), May (5%), June (-11%), July (-68%), and August (-88%). Reduction of mastitis treatments was evident every month, with the exception of May where 10 animals were treated before starting vaccination program in the herd and 11 were treated after.

Conclusions: Results show that vaccination against *Staphylococcal* mastitis can effectively minimize the amount of mastitis treatments (antibiotics and NSAIDs) in the herd. Furthermore, the drop in mastitis treatments was associated with a reduction in mastitis cases. These results suggest that including vaccination in a mastitis control program may be a good approach to prevent the disease and reduce the use of mastitis treatments, thereby improving milk quality and public health.

Reproductive Tract Surgeries in Sheep under General Inhalational Anaesthesia

Barbara Lisowska¹Bartosz Pawlinski²Katarzyna Siewruk³Michał Trela²Ricardo Faundez⁴Michał Dabrowski²Zdzisław Gajewski⁵

¹Anesthesiology and Intensive Care, Independent Public Hospital Prof. Adam Gruca CMPK in Otwock, Otwock, ²Dep. for Animal Reproduction, WCB, CBB, ³Department for Animal Reproduction, ⁴Dep. for Animal Reproduction, FVM, Warsaw University of Life Sciences, ⁵Dep. of Animal Reprod, CBB, WCB, Warsaw University of Life Sciences, Warsaw, Poland

Objectives: Sheep (*Ovis aries*) is gaining acceptance as an established model for research about small ruminant reproductive tract physiology. The aim of the study was to record myoelectric activity of the reproductive tract following induced oestrus with different synchronisation protocols during reproductive season.

Materials and Methods: The 9 Polish Landrace sheep were enrolled into the study. The elective surgical procedure under general inhalational anaesthesia was performed in all animals. The general inhalational anaesthesia (sevoflurane in oxygen; Sevoflurane Baxter) with endotracheal intubation following intramuscular premedication (midanium 0,4 mg/kg; Midanium 5mg/ml Polfa Warszawa S.A., ketamine 4mg/kg; Bioketan 50 ml Vetoquinol Biowet PL) and intravenous induction (propofol 4mg/kg; Scanofol 10mg/ml ScanVet Poland) was performed due to the laparotomy. The silicone base silver bipolar electrodes were adapted to be sutured on oviduct and uterine horn. Sheep were surgically fitted

with TL10M3-D70-EEE (DSI, St. Paul, MN, USA) implants positioned between the abdominal muscles, and 3 silicone electrodes sutured on the left or right oviduct (bulb and isthmus) and the corresponding uterus horn. The myoelectric activity was recorded using the DL10 analog output (DSI) coupled to PowerLab (ADInstruments, Melbourne, Australia) and PC computer. The postoperative antibiotic therapy with amoxicillin 1ml/10kg (Betamox L.A 150mg/ml; ScanVet Poland) in combination with postoperative analgesia meloxicam 0,5 mg/kg (Metacam 5mg/ml; Boehringer Ingelheim Vetmedica) was proceed for 5 days. The sheep after the research underwent euthanasia with intravenous injection of phentobarbital 0,3- 0,6 ml/kg (Morbital; Biowet Puławy) to collect tissues for histopathology examination.

Results: The maintenance of general anaesthesia (sevoflurane in oxygen) was smooth and easier to control compared with general anaesthesia maintenance with isoflurane in oxygen. No complications like heart arrhythmias, respiratory depression and anaphylactic reaction were observed during surgery. The recovery process after endotracheal tube removal was much faster (5 min- standing position) without complication in intensive care room for large animals compared with recovery process after isoflurane administration (15 min). The back to consciousness after sevoflurane anaesthesia is faster than after isoflurane anaesthesia which is preferably especially in ruminants.

Conclusions: General inhalational anaesthesia (sevoflurane in oxygen) allows for optimal however safely, painless management of the highly complicated, long surgeries on reproductive tract in sheep. Furthermore, the medical sciences state of art progress affords application of the latest anaesthetic drugs and techniques allowing to minimize pain and distress in animals especially during long surgical procedures.

Left Flank Ovariohysterectomy as The Final Surgical Treatment of the Pseudopregnancy in Pet Goat

Katarzyna Siewruk¹Michał Trela²Ricardo Faundez³Bartosz Pawlinski²Michał Dabrowski²Barbara Lisowska⁴Zdzisław Gajewski⁵

¹Department for Animal Reproduction, ²Dep. for Animal Reproduction, WCB, CBB, ³Dep. for Animal Reproduction, FVM, Warsaw University of Life Sciences, ⁴Anesthesiology and Intensive Care Department, Independent Public Hospital them. Prof. Adam Gruca CMPK in Otwock., ⁵Dep. of Animal Reprod, CBB, WCB, Warsaw University of Life Sciences, Warsaw, Poland

Objectives: Nowadays goats are not only farm animals but also kept as outdoor pets at modern eco type or agro tourism farms in particular. However, individual approach is essential while the treatment routine of the most common pathologies. Pseudopregnancy is one of the major causes of anestrus in goats during the reproductive season. It is characterized by the persistence of a corpus luteum in the absence of a (viable) conceptus in the uterus. The primary clinical feature is hydrometra (accumulation of fluid in the uterus) imitating the normal pregnancy development.

Materials and Methods: The two and a half year old dairy goat was brought to the clinic with severe bilateral abdominal enlargement. The goat had never been naturally mated or artificially inseminated. A clinical examination was done and all the basic life parameters evaluated were normal. The large volume of fluid accumulated inside the uterus was confirmed by ultrasound examination. During the previous as well as the present breeding season, the goat was administered a single dose

of prostaglandin F2 alpha and oxytocin; nevertheless the hydrometra reoccurred. Radical surgical treatment was demanded by the goat owner. A general inhalational anesthesia (sevoflurane in oxygen; Sevoflurane Baxter) with endotracheal intubation following intramuscular premedication (midanium 0,4 mg/kg, ketamine 4mg/kg) and intravenous induction (propofol 4mg/kg) was chosen in order to perform left flank ovariohysterectomy. During surgery the total amount of accumulated fluid of 15 liters was evacuated prior to removing uterus and ovaries. A postoperative antibiotics penicillin with dihydrostreptomycin 1ml/20 kg (Depomycin; ScanVet Poland) in combination with non-steroidal anti-inflammatory drug flunixin 2 mg/kg (Flunimeg; ScanVet Poland) was administrated.

Results: The maintenance of general anaesthesia (sevoflurane in oxygen) was smooth and easier to control compared with general anaesthesia maintenance with isoflurane in oxygen. No complications like heart arrhythmias, respiratory depression and anaphylactic reaction were observed during surgery. The recovery process after endotracheal tube removal was much faster (5 min- standing position) without complication in intensive care room for large animals compared with recovery process after isoflurane administration (15 min). The back to consciousness after sevoflurane anaesthesia is faster than after isoflurane anaesthesia which is preferably especially in ruminants.

Conclusions: Nowadays goats are not only farm animals but also kept as outdoor pets at modern eco type or agro tourism farms in particular. However, an individual approach is essential when treating the most common pathologies. General inhalational anesthesia (sevoflurane in oxygen) allows for optimal however safely, painless management of the highly complicated, surgeries on reproductive tract in goats. Furthermore, the medical sciences state of art progress affords application of the latest anaesthetic drugs and techniques allowing to minimize anaesthetic risk, pain and distress of the goat.

General Inhalational Anaesthesia for the Surgery of the Urinary Tract in Goat Model

Michał Dabrowski¹Katarzyna Siewruk²Michał Trela¹Ricardo Faundez³Barbara Lisowska⁴Bartosz Pawlinski¹Zdzislaw Gajewski⁵

¹Dep. for Animal Reproduction, WCB, CBB, ²Departament for Animal Reproduction, ³Dep. for Animal Reproduction, FVM, Warsaw University of Life Sciences, ⁴Anesthesiology and Intensive Care Department, Independent Public Hospital them. Prof. Adam Gruca CMPK in Otwock., ⁵Dep. of Animal Reprod, CBB, WCB, Warsaw University of Life Sciences, Warsaw, Poland

Objectives: Goat (*Capra hircus*) is gaining acceptance as an established model for biomedical research and for surgical training moreover in preclinical toxicological testing of pharmaceuticals. Goats can be gentle, easy to handle and transport, intelligent, affectionate, friendly, and clean and are increasingly being used as an alternative to the dog or monkey. The aim of the study was the transurethral injection of the mesenchymal stem cells then urodynamic, follow up examinations at certain intervals.

Materials and Methods:The 30 polish white landrace goats were enrolled into the study. The elective, surgical, research procedure under general inhalational anesthesia was performed in all animals. The general inhalational anesthesia (isoflurane in oxygen; Aerrane Baxter) with endotracheal intubation following intramuscular premedication (midanium 0,4 mg/kg; Midanium 5mg/ml Polfa Warszawa S.A. , ketamine 4mg/kg; Bioketan 50 ml Vetoquinol Biowet PL) and intravenous induction

(propofol 4mg/kg; Scanofol 10mg/ml ScanVet Poland) was applied due to the surgery. The postoperative antibiotic therapy with amoxicillin 1ml/10kg (Betamox L.A 150mg/ml; ScanVet Poland) in combination with postoperative analgesia meloxicam 0,5 mg/kg (Metacam 5mg/ml; Boehringer Ingelheim Vetmedica) was proceed for 5 days. Goats after the research underwent euthanasia with intravenous injection of phentobarbital 0,3- 0,6 ml/kg (Morbital; Biowet Pulawy) to collect tissues for histopathology examination and to obtain urethral explants after stem cells transplantation for analysis with In Vivo Imaging System (IVIS).

Results: The maintenance of general anaesthesia (sevoflurane in oxygen) was smooth and easier to control compared with general anaesthesia maintenance with isoflurane in oxygen. No complications like heart arrhythmias, respiratory depression and anaphylactic reaction were observed during surgery. The recovery process after endotracheal tube removal was much faster (5 min- standing position) without complication in intensive care room for large animals compared with recovery process after isoflurane administration (15 min). The back to consciousness after sevoflurane anaesthesia is faster than after isoflurane anaesthesia which is preferably especially in ruminants.

Conclusions: General inhalational anesthesia allows for optimal however safely, painless management of the highly complicated, research surgeries on reproductive tract in goat model. Furthermore, the medical sciences state of art progress affords application of the research animals however pain and suffer have to be reduced.

Positive effects of Butafosfan with vit B12 (Coforta B12) on the reproductive efficiency in ewes on pasture under a synchronization program in Chile

Antonio Bocic¹ on behalf of Concepcion Raul Vazquez² on behalf of Bayer AH

¹Reproduction, Veterinary Faculty Univ Concepcion, Concepcion, Chile, ²Veterinary Services, Bayer Animal Health, Monheim, Germany

Objectives: Butaphosfan with Vit 12 (Coforta B12) is widely used in bovine as a metabolic enhancer, to improve energy balance and metabolic status. There is no information documented about the use of this product to improve the body condition in ewes on pasture with a consequent effect in reproduction parameters. The objective of this paper was to evaluate the reproduction parameters in ewes on pasture and under a synchronization program with progesterone implant

Materials and Methods: The study was done in a farm in the South of Chile. 466 ewes on pasture and under synchronization program with progesterone intravaginal device + prostaglandin F2 alfa. Animals were randomly allocated in 3 groups. The group 1 (232 ewes) remained as control, they received the progesterone device. Groups 2 and 3 (234 animals divided in 2 groups) received after the implantation of the device 5 ml of Coforta B12 (500 mg butaphosfan + 0.25 mg of Vit B12). Group 3 received a second injection (same dose) of Coforta B12 10 days later. After this all groups were taken to the males for breeding (1 male / 25 synchronized ewes). Fertility rate and prolificity (number of lambs/ ewe) were statistically evaluated.

Results: Fertility rate was improved by 7.1% in the group which received one injection of Coforta B12 compared with the control (73.9% vs 66.8%). The group with 2 injections the fertility rate was significantly increased

uo to 87.7% ($p < 0.05$). Better prolificity was detected in the treated groups, in the group 1 was lower (1.13), group 2 showed a rate of 1.22 and 1.32 in the group 3. There was no statistical difference between control group and group 1, but group 3 shows a significant difference in comparison with control group (Kruskal-Wallis statistical method)

Conclusions: Based on the current findings a significant positive influence is detected in those synchronized animals with 2 treatments with Coforta B12, mostly in the fertility rate. In the case of prolificity the numerical difference shows also a significant benefit

Comments: This study could be the basis for future ones, considering animals on pasture, with potential problems in body condition that can affect the reproduction parameters.

P01-001-148

Effect of phosphorus and calcium supplementation on goat performance communally grazed in a semi-arid area of Republic of South Africa.

Mpho Sylvia Tsheole¹; Frank N. Bakunzi¹; Mulunda N. Mwanza²

¹Animal Health, North West University, Mafikeng, ²Animal Health, North West University Mafikeng Campus, Mahikeng, South Africa

Objectives: The main aim of the research was to evaluate the levels of phosphorus and calcium in goat faeces, blood and in the pasture in the semi-arid area of the North West Province and to assess the effect of selected mineral (P and Ca) supplementation on goat's health and production.

Materials and Methods: In this study, a total number of 24 female goats, two years of age were purchased from local farmers around Mafikeng. The goats were randomly grouped into two groups of 12, the control and the supplemented groups respectively. The supplemented group was fed dicalcium phosphate ad lib in the evenings for 12 months. Faecal, blood and grass samples were collected monthly, in addition to body mass of individual animals. Calcium (Ca), Phosphorus (P) and Magnesium (Mg) samples were analysed using the Spectrophotometer and ICP-MS.

Results: Results obtained showed that Ca and P supplements did not influence both faecal and serum P levels as compared to the untreated goats. However, Ca and P supplemented goats displayed significant ($P < 0.05$) serum Ca and Mg concentrations increase. This showed the significance of supplementing Ca and P supplements to grazing communal goats in this region. In addition, significant ($P < 0.05$) body mass gain were recorded in goats supplemented with Ca and P as compared to non-supplemented goats throughout the trial period, again emphasizing regular P and Ca supplements to grazing goats in semi-arid areas.

Conclusions: The results obtained in this study have confirmed the hypothesis in semi arid areas of south Africa such as Mafikeng, supplementation of Ca and P is needed in semi-arid areas in order to improve productivity in goat farming.

P01-001-149

The influence of the chosen various factors on the fecundity of the Olkuska breed during the natural reproductive season

Michał Dzieciol¹; Jacek Mrowiec¹; Piotr Nowakowski²; Wojciech Nizanski¹; Marta Iwaszkiewicz³

¹Department of Reproduction and Clinic of Farm Animals, ²Institute of Animal Breeding, ³RZD Swojec, Wrocław University of Environmental and Life Sciences, Wrocław, Poland

Objectives: The Olkuska ewes are known to display usually a high litter size. However due to various, sometimes unknown reason this feature is not always clearly demonstrated. The aim of this study was to evaluate the possible methods of increasing the litter size in Olkuska ewes during the natural reproductive season.

Materials and Methods: During experiment 40 adult ewes of Olkuska sheep were used. The animals were randomly divided on three groups. The females from group A ($n=10$) were synchronized with the use of sponges containing 20 mg of flugestone acetate (Chronogest, Intervet) with injection of 450 IU of serum gonadotropin (Folligon, Intervet) at the time of sponges withdrawal. Ewes from group B ($n=10$) were treated according the same protocol with additional administration of Sildenafil citrate as a vaginal suppositories twice with the interval of one day. Suppositories containing 100 mg of active substance were applied deep into vagina after sponges withdrawal and then after next 12 hours. The animals from group C ($n=20$) did not received any protocol and were treated as a control group. Two rams (1 and 2) were used for mating. Every mating was recorded.

Results: Obtained results revealed the highest fertility in the control group (80%, 90% and 95% in group A, B and C respectively) however the highest fecundity were observed in the group B (189%) vs. 150% and 179% in groups A and C respectively. Average number of lambs per ewe was the same in groups B and C (1,7), but in group A was much lower (1,2). Average period from putting rams to lambing was similar in all groups: 150,25 vs. 150, 67 vs. 156,79 days in group A, B and C respectively. Average litter size after both rams mating was also alike: 1,60 and 1,55 in ram 1 and 2 respectively.

Conclusions: Previous study of different authors proved the effectiveness also in sheep and cows of sildenafil as effective and selective inhibitor of phosphodiesterase type 5 (PDE5) in improving the blood flow in reproductive organs (uterus, placenta). This effect achieved by relaxation of the smooth muscle cells of blood vessels what in turn induce of vasodilatation could be responsible for the highest input of the active substances into the reproductive organ and in turn creation of the better environment for the effective ovulation, nidation and pregnancy maintenance.

Comments: However this is just a hypothesis, obtained results suggest the need of further studies performed on the bigger number of animals, which could verify presented hypothesis.

Serum Proteins Of Sheeps Infected With Haemonchus contortus

Karina Calciolari ¹Daniela Queiroz ^{1,2,*}Nara S. Bernardi ¹Carolina Buzzulini ¹José Jurandir Fagliari ¹

¹Departamento de Clínica e Cirurgia Veterinária, Unesp Jaboticabal, Jaboticabal, ²Centro Universitário Barão de Mauá, Ribeirão Preto, Brazil

Objectives: Population growth associated with the need for less costly agricultural activities makes the sheep industry a profitable alternative to animal protein production. Among the diseases that affect sheep, parasitism by gastrointestinal nematodes, especially *Haemonchus contortus*, represents a serious health problem causing significant economic losses. Acute phase proteins are produced by liver and their synthesis is associated with acute infections and inflammations and are important in the early diseases diagnosis. Therefore, we studied serum protein profile of pure and crossbred sheep experimentally infected by *H. contortus*.

Materials and Methods: 10 lambs, 5 Santa Inês (SI) and 5 crossbred Dorper x Santa Inês (DSI), male, weanling, confined for 60 days at Centro de Pesquisas em Sanidade Animal (CPPAR) - UNESP Jaboticabal. The animals received orally inoculum containing 1,000 infective larvae (L3) of *H. contortus* and were subjected to blood collection in tube without anticoagulant (10 mL) for determination of protein profile by SDS-PAGE technique, and feces collection to perform the EPG (eggs per gram) in basal times (D0), 20, 40 and 60 days after experimental infection (D20, D40 and D60 respectively). For statistics was used completely randomized design submitted to analysis of variance and the means were compared by Tukey test at 5% significance level. Acute phase proteins assayed were: albumin, IgA, IgG, ceruloplasmin, haptoglobin, transferrin and α -acid glycoprotein.

Results: Serum albumin concentrations, ceruloplasmin and transferrin were significantly different between the DSI and SI groups in all studied moments, and had lower albumin concentration in the DSI group when compared to the SI group. For ceruloplasmin and transferrin were observed significantly higher averages in the DSI. IgA concentrations were significantly different only in D20, being the concentration two times lower in SI group when compared to the DSI, however during the entire experimental period DSI group showed higher numerical values of IgA. With regard to IgG, at all times, there was a higher serum concentration in the SI group compared to DSI but with no significant difference. The concentration of proteins haptoglobulin and α - acid glycoprotein showed no significant difference between groups. And the quantity of eggs in feces of SI group was three times higher (1745 epg) than DSI (502 epg) in D40, day with higher egg counts.

Conclusions: This study shows that Dorper X Santa Inês crossbred sheep have a better immune response and consequently more resistance to parasites when compared to Santa Inês sheep, making it a good breeding option when considering susceptibility to parasites.

Objectives: This paper reports a case of penile hematoma in an adult sheep, not due to trauma by sexual activity. This condition is one of the most prevalent disease in the penis, usually occurring during copulation, having been described in cattle but not for sheep, according to the literature.

Materials and Methods: A ram of 18 months of age in reproductive rest and secluded to females, confronted another male after escape. The animal was subjected to systemic non-steroidal anti-inflammatory therapy for three days due to increased volume at the ventral region of perineum and held in sexual rest for 60 days. After five months of trauma, the animal was with inability to expose the penis, although libido, and due a volume of 15cm diameter distal to the perineum, sensitive to palpation and with floating regions. In ultrasonography exam was visualized a structure circumscribed with not homogeneous echogenicity content, suggestive of penile hematoma, confirmed after centesis. Surgery was indicated because of the size of the lesion and time of evolution. The patient underwent intravenous general anesthesia and epidural lumbosacral anesthesia and surgery was initiated with skin incision in the central region of the volume increase. After removal of the clots, it was possible to expose the penis which was surrounded by a fibrous capsule and sigmoid flexure and identify in the site of injury. The fibrous capsule and adjacent penile adhesions were removed, making it impossible to rebuild the tunica albuginea because of their degree of commitment. After the surgery was instituted seven days of penicillin procain, 10 days of flunixin meglumine, and hydrotherapy in testicular scrotal skyn followed by cold compresses on the operated area, three times daily for 10 days. The points of skin were removed after 15d and the patient was discharged, under the supervision of sexual rest for 60 days.

Results: Two months later to the surgery, the patient returned with increased floating testicular volume, without sensibility and with leucopenia and increased fibrinogen. In ultrasonographic examination, an isolated structure involving an irregular echogenic liquid, suggestive of abscess was visualized, confirmed by centesis, being sent to orchiectomy. In addition to this report describe the penile hematoma in sheep, describes a pathogen also not yet been described in the literature as penile injury was due to an indirect trauma rather than direct trauma to the erectile penis during copulation. The location of the volume increase observed in sheep this report, dorsal to the scrotum, also differs from the literature and has been attributed to how the injury occurred without exposure or penile erection, which may have favored a more dorsal rupture the flexure sigmoid.

Conclusions: Complications like abscesses and adherences are common in the penile hematoma, especially in chronic and serious injuries, as was the case in the ram this report. The penile hematoma can occur not only in copulation, but indirect penile trauma with location of injury caudal to the scrotum in sheep. The size of the penile hematoma is an important parameter for the decision of conservative or surgical therapy and precocity in treatment is fundamental to a more favorable prognosis.

Estimulation Of Sexual Behavior Of Adult Dorper Rams Treated With Glutamate And(Or) Testosterone During Increased Photoperiods-Spring In Northern Mexico

Guadalupe Calderón-Leyva ¹Rafael Rodríguez-Martínez ^{1,*}Oscar Ángel-García ²Gerardo Arellano-Rodríguez ²Pedro A. Robles-Trillo ²César A.

Meza-Herrera³Gerardo F. Véliz-Deras¹

¹Ciencias Médico Veterinarias, ²Producción Animal, Universidad Autónoma Agraria Antonio Narro, Torreón, Coahuila, ³URUZA. Universidad Autónoma Chapingo, Bermejillo, Dgo., Mexico

Objectives: This study aimed to evaluate of different treatments upon reproductive parameters as well as their effectiveness to induce sexual behavior of rams under natural lighting conditions of spring -increased photoperiods-, the natural sexual resting season in Northern Mexico (25° N, 103° W).

Materials and Methods: Dorper rams (n=20; 2-3 yr. old, 81±0.32 kg body weight (BW); 3.8±0.05 body condition score (BCS) were divided in four homogeneous groups in terms of BW, BCS, scrotal circumference (SC) and odor (OD), and were randomly assigned to four experimental groups: 1). Glutamate Group (GG, n=5; treated 7 mg kg⁻¹ BW of L-Glutamate i.m. every 4d x 30d); 2). Testosterone Group (TG, n=5; treated with 0.5 ml saline every 4d x 15d + 25 mg of testosterone i.m. every 3d x 15d); 3). Glutamate + Testosterone Group, (GTG, n=5; receiving 7 mg kg⁻¹ BW of L-Glutamate every 4d x 30d + 25 mg of testosterone i.m. every 3d x 15d, the last 15d) and 4). Control Group (CONT, n=5; which received 0.5 mL of saline i.m. every 4d x 30d). On days 1, 15 and 30 BW, BCS, SC and OD of rams were measured; OD was classified by smelling the base of the horns at a distance of 15 cm and using a 0-3 scale. After 30d of treatments, two males were randomly selected from each treated group and exposed to four groups of anovulatory ewes (n=14 each; 42±2.36 kg BW; 3.04±0.22 BCS) to evaluate the male sexual behavior, considering three responses: 1). Appetitive sexual behavior (ASB; flehmen, anogenital sniffing, approaches, kicking, vocalizations, draw the penis), 2). Consummatory sexual behavior (CSB; mount attempts and mounts) and 3). Isolation behavior (ISL; standing, escape attempt, lying down and lying down time), during 2-h daily x 2 d. While BW, BCS, SC and OD data were evaluated by ANOVA, sexual behaviors considered X² (SYSTAT 12.0).

Results: No differences (P>0.05) regarding BW, BCS, SC and OD score were observed at the onset of the experiment among experimental groups. The same was true regarding BW, BCS and SC at the end of the experimental period, with 80.9±0.33 kg, 3.5±0.07 units and 35.23±0.2 cm, respectively. Yet, on d15, the GTG depicted the strongest odor score (1.5±0.22, P<0.05) regarding GG, TG and CG (0.75±0.20, 0.4±0.24 and 0.10±0.10, respectively; P>0.05). However, on d30, no differences (P>0.05) occurred among the GTG, GG and TG groups (1.5±0.2, 0.9±0.2 and 0.8±0.3, respectively) with the lowest value detected in the CG (0.6±0.1) which differed with the GTG (P<0.05). Results of sexual behavior showed that in the ASB, the GTG depicted the highest percentage of performed behaviors regarding GG, TG and CONT (43 vs 29, 11 and 18% respectively), yet, only differences (P<0.05) occurred between TG and CONT. In the CSB-phase, the GG and GTG depicted the largest percentage of behaviors, with the lowest values (P<0.05) depicted by both the TG and CONT (20%). In the case of ISL, the CONT accumulated the highest percentage (62%; P<0.05) regarding GTG, GG and GT (25, 13 and 0%, respectively).

Conclusions: Results demonstrate that Dorper rams treated with glutamate + testosterone during the natural sexual resting season in Northern Mexico promoted not only an increased odor score but also an augmented consummatory sexual behavior when exposed to increased photoperiods during the natural resting season in Northern Mexico. Such promissory results encourage delineation of reproductive management strategies to increase reproductive outputs during the out-of-season period in the sheep industry.

Radiographic Lung Alterations In Premature And Full-Term Lambs

Fernanda Bovino¹Eduardo M. Panelli¹Daniela S. Denadai¹Rafaela S. Baptista¹Natalia M. Rahal¹Larissa G. Ávila¹Natalia C. Souza¹Luciana D. R. Pinoti¹Flavia A. Lucas¹Juliana R. Peiro¹Francisco L. F. Feitosa¹Luiz Claudio N. Mendes^{1*}

¹Univ Estadual Paulista - Unesp - FMVA - Campus de Aracatuba, Aracatuba, Brazil

Objectives: The aim of this study was to describe and compare the thoracic radiographic changes in full-term lambs borned by normal delivery and cesarean section and premature lambs delivered by cesarean section. Forty three lambs divided into six groups: two groups were normal for gestational age and four groups preterm.

Materials and Methods: The normal groups were: normal delivery group (NORM, n= 9) and normal for gestational age but delivered by cesarean section group (143 days) (NORMCS, n=7). All the four premature groups were delivered by cesarean section in 138 days of gestation. The premature groups were: premature group (PRE, n=5), premature group whose mothers received dexamethasone (16mg/ IM) 36 hours before surgery (DEX, n=7), premature group that the lambs received surfactant intra tracheal instillation (100mg/kg) immediately after birth (SURF, n=6) and the last one premature group whose mothers received dexamethasone (16mg/ IM) 36 hours before surgery and the lambs received surfactant intra tracheal instillation (100mg/kg) immediately after birth (DEXSURF, n=6). The lateral thoracic radiographs were taken immediately after birth (M0), twenty-four hours (M₂₄) and forty-eight hours (M₄₈) after birth using a portable x-ray machine. All radiographs were made at 40kVp and 2 mA at a 100 cm focus-film distance. Fisher's exact test was used to determine if there were any differences between the groups in each moment; significance was set at P < 0,05. All changes were grouped to perform the statistical analysis, so we have lamb with or without radiographic changes.

Results: Radiographic changes are dependent of the group at M0 (p=0,0337) when compared NORM group with NORMCS group. When compared four premature groups (PRE, DEX, SURF and DEXSURF) the radiographic changes are dependent of the group at M48 (p=0,0057). When compared five groups of lambs delivered by cesarean section (NORMCS, PRE, DEX, SURF and DEXSURF) was not found differences between the moments. Immediately after birth (M0) the radiographs of the SURF group revealed 100% (6/6) of pleural effusion. Radiographic changes were noted in NORM 44.44% (4/9), NORMCS 100% (7/7), PRE 83.3% (5/6), DEX 66.7% (6/9) and DEXSURF 100% (6/6) groups. At M24, 55.6% (5/9) of NORM, 50% (3/6) of NORMCS, 75% (3/4) of PRE, 57.1% (4/7) of DEX, and 100% (5/5) of DEXSURF showed changes. After 48 hours (M48), 77.8% (7/9) of NORM and 66.66% (4/6) of NORMCS showed no changes, 75% (3/4) of PRE lamb showed changes in alveolar patterns and 85.7% (6/7) of DEX lambs showed changes in alveolar patterns (4/6), bronchial patterns (1/6), and interstitial, alveolar and bronchial patterns (1/6). The DEXSURF lambs (100%; 5/5) showed changes in interstitial and alveolar patterns (3/5), and interstitial, alveolar, and bronchial patterns (2/5). All deaths occurred before 24 hours of life. Two lambs died in each of the PRE and DEX groups, six (100%) died in the SURF group, and one died in the NORMCS and DEXSURF treatment groups.

Conclusions: We conclude that if the lambs show diffuse infiltrates, the ones that received a surfactant treatment, will have a poor prognosis. The lambs borned by cesarean section in normal age gestation presented more alterations than the ones spontaneous delivered. The period of 48 hours for lambs borned by normal delivery and normal for gestational

age but delivered by cesarean section was sufficient to remove the lung fluid, while the premature lambs still showed changes in the thoracic radiographic patterns.

A proposal for a classification of phimosis in lambs

Natália M. Rahal¹Rafaella S. Baptista¹Fernanda Bovino¹Bianca Gerardi¹Flavia A. Lucas¹Juliana R. Peiro¹Lina Maria W. Gomide¹Francisco L. F. Feitosa¹Luiz Claudio Mendes^{1,*}

¹Univ Estadual Paulista - Unesp - FMVA - Campus de Aracatuba, Aracatuba, Brazil

Objectives: The aim is to propose a classification for different degrees of phimosis in lambs, given the lack of information and varied forms of this presentation in these animals, as well as the possible correlation of predisposition to urolithiasis with this anatomical condition.

Materials and Methods: Were evaluated 119 lambs between three and four months old, of different breeds or crosses (Dorper, Ile de France, Santa Inês, Suffolk e Texel), average weight of 31.4 ± 4.68 kg, from a feedlot in the Teaching Veterinary Hospital of the FMV – Aracatuba campus of the Univ Estadual Paulista “Julio de Mesquita Filho”- Unesp. For evaluation, the animals were contained seated, with subsequent penile exposure, verifying the presence or absence of phimosis and a classification in grade, according Kikiros, Beasley and Woodward (1993), adapted to the anatomy of sheep. The following grades were determined: I - normal animals, with full retraction without narrowing behind the glans, with total exposure of the appendix; II - full retraction with narrowing behind the glans; III - partial exposure of the glans and appendix limited by foreskin; IV - discrete retraction, but there is no exposure of the glans, appendix and urethral meatus; V - no foreskin retraction is possible.

Results: According to the proposed classification, normal animals accounted 83.19%. Animals that showed complete retraction with narrowing behind the glans, classified as grade II, amounted to 7.56% (nine animals). The five lambs identified as grade III, accounted for 4.20%. Meanwhile, sheep with a slight retraction, non exposed glans, appendix and urethral meatus were four, totaling 3.36%. Only one of the evaluated animals (0.84%) did not presented any possible foreskin retraction, being classified as grade V.

Conclusions: The classification adapted from Kikiros, Beasley and Woodward (1993) proved to be effective on the identification of degrees of phimosis in lambs. Thus, the proposed method can be applied as a routine practice in the sheep medicine.

Physiological and blood parameters of sheep in Brazil

Luiza Seixas¹Cristiano B. de Melo¹Candice B. Tanure¹Vanessa Peripolli¹Paulo Ricardo M. Lima¹Giane Paludo¹Débora Andréa E. Façanha²Vivian Fischer³Helder Louvandini⁴Conceita McManus^{1,*}

¹University of Brasília, Brasília, ²Universidade Federal Rural do Semi-

Árido, Mossoro, ³Universidade Federal do Rio Grande do Sul, Porto Alegre, ⁴University of São Paulo, Piracicaba, Brazil

Objectives: Reference values used in tropical and subtropical regions are based on sheep raised in temperate climate and those in Brazil are subject to different environmental stressors. Therefore, the aim of the present work was to define reference values for hematological and physiological parameters for sheep in Brazil.

Materials and Methods: A database with 5,081 observations of sheep in nonstressful environmental conditions (THI equal or below 70) with information on time of day, sex, age, breed, physiological and hematological characteristics and environmental variables was elaborated. Because of the variety of breeds, they were grouped into types: commercial wool (CW), locally adapted (LA) and locally adapted x wool (NW).

The physiological and blood characteristics evaluated included: rectal temperature (RT), respiratory rate (RR), heart rate (HR), packed cell volume (PCV), total plasma protein (PPT), number of red blood cells (RBC), hemoglobin concentration (HB), mean corpuscular volume (MCV), mean corpuscular hemoglobin concentration (MCHC), number of white blood cells (WBC), monocytes (MONO), lymphocytes (LYMP), eosinophils (EOSI), segmented neutrophils (SEGM), platelets (PLAT) and fibrinogen (FIBR).

Statistical analysis was performed using SAS® (Statistical Analysis Institute, Cary, North Carolina) with significance level of 5%. The procedures used included analysis of variance, averages and confidence interval of 95% (pctpts command in PROC UNIVARIATE).

Results: Most of the means of the studied parameters were within published reference values for the species. However, the values of 2.5 and 97.5 percentiles, which indicate the lower and upper limits, respectively, differed from those previously established in textbooks. Respiratory rate was the parameter showing highest divergence, with values far above normal range (20-34 movements/minute) for sheep in all types and age groups. Similarly, upper and lower heart rate limits were not within reference intervals (70-80 movements/minute), and in CW adult group the average heart rate (113.51 beats/minute) was also higher than values previously reported. The maximum rectal temperatures of CW (40.7°C) and LA (40.3°C) adult sheep and animals young were also higher than those considered as normal (38,3 - 39,9°C).

The lower and upper limits of packed cell volume were lower than the reference values (27-45%), and the 2.5 percentile was outside the normality range. In general, minimum values of the number of red blood cells and hemoglobin concentration of all types and age groups also differed from reference limits.

Mean number of leukocytes was within the reference range, however maximum and minimum limits were different. A greater number of red blood cells, lower concentration of hemoglobin and MCHC were observed in young sheep. Adult animals had higher TPP, PLAT and FIBR. As for the type, CW had higher TPP (7.51g/dl) and LA adult higher PLAT (734.36 x 10³/µL). In the leucogram, lower number of leukocytes was observed in young NW group (7.47 x 10⁶/µL).

Conclusions: Although means of most parameters were within textbook reference ranges for sheep, the upper and lower limits of many variables were different from the reference values, with significant number of observations outside reference interval. Therefore, considering that physiological and hematological parameters are essential to evaluate pathological disorders, animal welfare and adaptability to the environment, the use of reference values based on animals with similar breed characteristics and subjected to similar environmental conditions is recommended for a correct interpretation of the results.

Serum Ceruloplasmin, Haptoglobin And A1-Acid Glycoprotein As Markers Of Induced Mastitis In GoatsKalina Simplicio¹, Diana C. C. Sanchez¹, Hugo B. Brunetti¹, Thaís G. Rocha¹, Ana Maria C. V. Martins², José J. Fagliari³¹Veterinary Clinics Department, São Paulo State University, UNESP, Brazil, Jaboticabal, SP, ²São Paulo University, USP, Pirassununga, ³Veterinary Clinics Department, São Paulo State University, UNESP, Jaboticabal, SP, Brazil

Objectives: Acute phase proteins (APP) are sensitive and early indicators of inflammation. However, information regarding goats APP are scarce. Therefore the aim of this study was to determine serum concentration of ceruloplasmin, haptoglobin and α_1 -acid glycoprotein in goats with induced *Staphylococcus aureus* (Group I) and *Streptococcus agalactiae* (Group II) mastitis in order to verify its importance as early biomarkers of mammary infection in these species.

Materials and Methods: This experiment was approved by the Ethics Committee on Animal Use (CEUA) from UNESP, Brazil under protocol number 011878/11. GI was composed of five Saanen goats inoculated through the teat canal with about 9.5×10^9 colony forming units (CFU) of *S. aureus* and GII consisted of five French Alpine goats inoculated with approximately 4.4×10^{11} CFU of *S. agalactiae*. The sampling moment immediately prior to inoculation was designated M0 and then daily sampling was identified as M1, M2, M3, M4, M5, M6 and M7 when blood and milk samples were obtained. Serum ceruloplasmin, haptoglobin and α_1 -acid glycoprotein were obtained by the SDS-Page Electrophoresis technique. Milk samples were used to monitor the development of clinical mastitis through the strip cup test, California Mastitis Test (CMT) and microbiological analyzes. Data were subjected to analysis of variance and the means to Dunnett test, considering a 95% significance level ($p < 0.05$).

Results: It was noted that the experimental infection model developed for the induction of clinical mastitis in goats was effective in both groups. Serum increase percentages of up to 254% in GI and 112% in GII were obtained for serum Ceruloplasmin. Haptoglobin concentrations showed percentages of serum elevation of 444% as early as 48 hours after inoculation (M2) in GI, and 2,000% in M3 in GII, with the highest elevation percentage of 2,500% being observed in the last sampling moment (M7) in GII. Serum α_1 -acid glycoprotein concentrations did not differ significantly from initial concentrations in goats from GI until the last sampling moment (M7) when there was an 84% elevation percentage. In GII there was no significant elevation percentage obtained. In this group the highest value observed was at M5 sampling moment, when it was observed a 14% elevation percentage compared to M0.

Conclusions: Serum Haptoglobin was an early and reliable marker in the detection and monitoring of experimental mastitis, whether induced by *S. aureus* or *S. agalactiae*. Ceruloplasmin was a moderate marker and serum α_1 -acid glycoprotein showed limited significance, being a better marker of chronic rather than the acute process in *S. aureus* induced mastitis.

Urinary Bladder Sonography And Antegrade Cystourethrography In Rams And Wethers With Obstructive UrolithiasisUschi Schwarz¹, Marlene Sickinger¹, Kerstin von Pückler², Kernt Köhler³, Martin Kramer²¹Clinic for obstetrics, gynecology and andrology with veterinary ambulance, ²Clinic for small animals (veterinary surgery), ³Institute for veterinary pathology, Justus-Liebig-University, Giessen, Germany

Objectives: Due to the predisposing anatomy of the urethra in small ruminants, obstructive urolithiasis continues to be a challenging problem with often unsatisfactory outcome. Several surgical techniques to restore normal urination in patients suffering from this disease have been described. Nevertheless, use of diagnostic measures (ultrasonography, cystourethrography) and longterm survival times are still rather limited. Therefore, diagnostic possibilities in cases of obstructive urolithiasis undergoing cystotomy versus laparoscopic tube cystostomy are described and outcome rates are compared.

Materials and Methods: Ultrasonographic examinations of the urinary bladder were performed in 26 male small ruminants suffering from obstructive urolithiasis and undergoing tube cystostomy via laparotomy (control group, n=13) or laparoscopy (test group, n=13) respectively. Horizontal and vertical diameters of the urinary bladder as well as a qualitative assessment of the bladder wall and its content were evaluated using a Mindray M5 (5.0 MHz). In patients with unresolved disturbance of urine passage after surgery antegrade urethrocytography was used to determine the localization of obstruction.

Results: Both surgical techniques used in this study resulted in a short term success rate of 69 %. Long term follow up for both techniques revealed a success rate of 46 %. Measurements of bladder diameters showed no significant differences between test and control group. In all patients presented with disturbed voiding ultrasonography displayed dilated urinary bladders with thin, hyperechogenic walls, hypoechogenic contents and in some cases small amounts of hyperechogenic sludge. Five out of the initially presented 26 animals showed persisting urethral obstructions after surgery. Due to lacking owner's consents, in only two patients an antegrade cystourethrography could be performed. In both cases filling defects in the area of the proximal flexura sigmoidea could be shown.

Conclusions: Success rates of both surgical methods are comparable to those already published, which continue to be unsatisfactory. To enhance surgical outcome new or modified techniques that are derived from small animal's surgery should be applied. Diagnostic measures including ultrasonography and antegrade cystourethrography are highly recommended as standard diagnostic procedures.

Supplementation with Vitamin "E" in Rambouillet Ewes during the Last Third of Pregnancy: Effect on Lamb Birth Weight

C.A. Meza-Herrera ¹, B. Ramirez-Omaña ¹, C.A. Nieto-Rosales ², F.J. Moron-Cedillo ³, C.E. Santamaría-Estrada ¹, C.A. Romero-Rodríguez ¹, C. Navarrete-Molina ¹

¹URUZA, Universidad Autonoma Chapingo, Bermejillo, Durango, ²CE-SLP, INIFAP, San Luis Potosí, SLP., ³FAV, UASLP, San Luis Potosí, Mexico

Objectives: The transfer of nutrients from dam to its fetus occurs by placental transport. However, vitamin E (VE), which functions primarily as an antioxidant, does not cross the placenta in any appreciable quantity. Consequently, pre-partum supplementation of VE is essential to promote an optimum fetal growth while a prime birth weight (BW). The aim of this study was to evaluate the possible effect of supplementation of VE during the last third of pregnancy upon BW. Besides, the influence of some non-genetic effects of variation upon BW expression in Rambouillet lambs, was also evaluated.

Materials and Methods: The study was conducted at the Faculty of Agriculture and Veterinary Medicine, UASL, San Luis Potosi, Mexico (22°NL, 1,835 m). Multiparous pregnant Rambouillet ewes (n=37 ewes, 71.5±1.75 kg, LW, ≥ 3 yr. old) were mated to a single Rambouillet sire of proven libido and fertility; during the breeding period, the exact date of mating was recorded. Starting on the last third of pregnancy (d -50), ewes were randomly divided in two treatments: 1) Control (CON; n=17, no vitamin E treatment) and 2) vitamin E-supplemented (VE; n=20, receiving 4 IU vitamin E kg⁻¹ LW. VE-injections considered a commercial product and contained 27.2 IU mg⁻¹ of α-tocopherol (Lab-Torneo, Mexico). Intramuscular injections were given weekly on the same day of the week at 0800 h, from late gestation (d -50) up to lambing (d0); a total of 50 lambs at birth (5.32±0.26 kg) were considered for the analysis. The defined model considered to BW as dependent variable while experimental group (EG), ewe lambing number (NL), litter size (LS), and of sex lambs (SL) as fixed effects; the variables NL, LS and treatments were included as covariates. Lambs were weighed with a Torino® hanging scale with a capacity of 10 kg and a minimal graduation of 20 g. The health status of the experimental units was controlled by an experienced veterinarian during the whole experimental period; no health problems were observed during the trial. All the methods and management of the experimental units were in strict accordance with accepted international guidelines for ethical use, care and welfare of animals in research.

Results: Birth weight is one of the most important factors influencing the pre-weaning growth of the young and the onset of puberty; a heavier birth weight is an indication of better nutrition level of the dam while promotes reduction of perinatal mortality of the newborn. However, in our study, VE-supplementation during late pregnancy did not affect the birth weight of the progeny; the least square mean average for BW was 5.2±0.16 kg. Besides, no differences (P>0.05) occurred between males (5.20±0.23 kg) and females (5.06±0.26 kg). Yet, BW was affected (P<0.05) by NL and LS; sheep with three lambings had heavier lambs (5.38 ± 0.16 kg) regarding to ewes with 2, 4, 5 and 6 lambings (5.38±0.18, 5.44±0.38, 5.09±0.17 and 4.41±0.17 kg, respectively). Simple born lambs were heavier than double (5.67 vs. 4.67±0.11 kg). Some studies have reported that oral tocopherol supplementation during the last third of pregnancy in sheep increased the mRNA expression of interleukins and different angiogenic factors in uterus, caruncles and cotyledons, affecting in a positive fashion fetal growth. Yet, the lack of any effect of supplementation of vitamin E in late gestation on birth weight agrees

with other studies. Certainly, maternal undernutrition did not affect the progeny's birth weight reported in this study which is within the range of birth weight for the Rambouillet breed.

Conclusions: Long term supplementation with VE during the last third of pregnancy in Rambouillet ewes did not affect the expression of the lamb birth weight, yet, NL and LS affected the phenotypic expression of BW. Therefore, once adjusted for the non-genetic factors causing genetic variation in the BW phenotypic expression, BW should be considered as an important selection criterion in sheep breeding programs to improve production efficiency of the flock.

P01-001-162

Expression Of Metalloproteinases 2 And 9 In Sheep With Acute Lactic Ruminal Acidosis And Laminitis

Amanda Festa Sabes ¹, Annita M. Girardi ¹, Paulo R. D. Rocha ², Daniela J. Queiroz ¹, Gisele F. Machado ³, Luiz C. Marques ¹

¹Clinical and veterinary surgery, FCAV/UNESP, Jaboticabal, ²Environmental and Experimental Pathology, UNIP, São Paulo, ³Clinic, Surgery and Animal Reproduction, FMVA/UNESP, Araçatuba, Brazil

Objectives: The ruminal acidosis, either in acute or subacute form, is considered one of the main etiopathogenic causes of laminitis. The matrix metalloproteinases (MMPs) are secreted as pro-enzymes by neutrophils, monocytes and macrophages in response to various stimuli. The laminar foot degradation caused by MMPs has been associated with inflammatory response due to release of MMPs activating factors from the bloodstream into the digits, contributing to the degenerative process, shown particularly in horses. This study aimed to evaluate the expression of MMPs 2 and 9 in sheep with acute lactic ruminal acidosis (ALRA) experimentally induced.

Materials and Methods: Ten animals received 15 g/kg of body weight of sucrose orally, and the blood samples were taken at the following intervals: 4, 8, 12, 16, 20, 24, 28, 32, 36, 48, 72, 96, 120, 144 hours and on the second, third and fourth following weeks. The samples were separated into serum fractions by centrifugation at 2,500g for 10 minutes. The serum fraction was stored at -80 in sterile plastic Eppendorf microtubes of 1,5 mL, to perform the zymographic test. The data was submitted to analysis of variance with repeated measures in time, where the crop was the tested factor (17 levels), with the animals constituting the blocks (10).

Results: During the clinical manifestations of ALRA five animals had alternating support of forelimbs, reluctance to get around in lateral position for a long time, forelimbs sensitives to palpation and temperature increased on the corneal area, characterizing the process of acute laminitis that began between 24 and 28 hours and it was evident even at 72h after induction of ALRA. Only the pro-active forms of MMPs were expressed in zymography gels with higher values occurring mainly between 32 and 144 hours.

Conclusions: In horses is believed that MMPs are also causes of laminitis after episodes of acute abdomen. In ruminants it is believed that MMPs have the same dynamic that shown in horses, and the results obtained in this study demonstrate that these enzymes play an important role on the genesis of acute laminitis after ALRA.

Right Abomasal Displacement In Six Pregnant Cows From Northeastern Brazil

Antonio Câmara¹, José Augusto B. Afonso², Carla L. D. Mendonça², José Renato J. Borges¹

¹Hospital Escola de Grandes Animais da Granja do Torto, Universidade de Brasília, Brasília, ²Clínica de Bovinos, Campus Garanhuns, Universidade Federal Rural de Pernambuco, Garanhuns, Brazil

Objectives: Right abomasal displacement (RAD) is a digestive disorder of high milk-yield cows and occurs mainly during the first six weeks post-partum. Therefore the occurrence during pregnancy is infrequent. This work aimed to report the clinical and laboratorial findings, and to evaluate the treatment choice in six pregnant cows with RAD.

Materials and Methods: Six 5 to 10-year-old crossbred cows were clinically evaluated due to sudden drop in milk yield, hyporexia and apathy. Clinical examination, hematological profile and ruminal fluid analysis were performed. Two moderate cases, without severe abdominal distention, appetite for roughage and metallic sound ("ping") reaching at the most the 8th intercostal space were treated conservatively, and four severe cases with moderate to severe abdominal distention associated to systemic disturbances were treated surgically by right flank pyloro-omentopexy.

Results: The management system was semi-confined with access to poor quality roughage and commercial bran (5-8kg/day). Pregnancy was accessed by rectal palpation and revealed two (n=2), five (n=1), six (n=1) and above eight (n=2) months gestation. Clinical evolution was 2-4 days. Clinical findings were apathy, dehydration, ruminal bloat, increased abdominal tension, "ping" varying from the 8th intercostal space to the right paralumbar fossa, splashing sound during right flank ballotement, and liquid blackish feces with mucus. Two cows also presented mastitis. Hematological exam was performed in three animals showing light leukocytosis (mean value: 13350/ μ L) by neutrophilia and hyperfibrinogenemia in one cow (1000mg/dL; reference: 400-700mg/dL). Ruminal fluid analysis showed compromised flora and fauna dynamics and increased chlorine ion concentration (mean value: 45,61 mEq/L). Four cows were surgically treated with a right flank pyloro-omentopexy, and two cows were clinically treated with transfaunation, dietary and hydro-electrolyte correction. All cows were discharged with no complications and deliver healthy calves.

Conclusions: Right flank pyloro-omentopexy showed to be a safe approach for the surgical treatment of RDA in pregnant cows, whilst the clinical protocol described was effective in treatment of light RDA when there is no systemic imbalance and the cow remain with appetite for roughage.

Use of bovine pericardium grafft for umbilical Hernioplasty in calf

Gertrud Elisa Campos Edler¹, Luis O. Lopes², Willer A. Santana¹, Izamara R. Araujo³, Otavio H. S. Martins⁴

¹Veterinary clinics and surgery - Veterinary Clinics Center, ²Adjunct professor Department of Clinics and Surgery Veterinary Medicine School, ³Graduate Studentery Department of Clinics and Surgery

Veterinary Medicine School, ⁴Graduate Studentery Department of Clinics and Surgery Veterinary Medicine School, UNIPAM, Patos de Minas, Brazil

Objectives: This study aims to describe the surgical approach to Umbilical hernia using bovine pericardium graft on the hernia ring in a heifer that arrived at the veterinary clinical center of the University Centre of Patos de Minas (UNIPAM). The animal have eight months, breed cross, 150 kg and had recurrence of umbilical hernia about 4 months, recurrence hernia since after 10 days of first surgery had been performed.

Materials and Methods: To do the second surgical procedure the animal was fasting for 12 hours, it was sedated with a combination of 2 mg / kg ketamine and 0.1 mg / kg xylazine 2%. Trichotomy was performed in the abdominal area and then antiseptis with chlorhexidine 2%. Local anesthesia around the hernia sac was with lidocaine epinephrine, 7 mg / kg. The heifer was placed on the operating table in ventral position and incision was about 15 cm in the midline, under hernia ring. Was remove adhesions of hernia and place suture cross mattress for closing hernia ring use polypropylene 2. The graft was stored in 98% glycerol for superior time than 15 days. Glycerol to be an excellent antiseptic and low antigenicity. Before use, bovine pericardium it was washed with 0.9% NaCl solution then left to hydrate in this solution for 30 minutes. The graft was cut as needed size and abdominal wall was scarified to increase grip. Then the pericardium was set 2 cm extending beyond the edges of wound, with nylon 2-0 and polyglycolic acid 1 used interchangeably with separate mattress suture, moreover, it was fixed to allow slight elasticity of abdominal muscles and prevent breakage of attachment points. The skin suture was performed with nylon number 0 place suture separate mattress. Pain control was performed 1.1 mg / kg flunixin meglumine for three days and antibiotic therapy ceftiofur sodium dose of 2.2 mg / kg for 5 days every 24 hours. Surgical wound cleaning was performed daily with chlorhexidine 2%.

Results: To obtain Rapid Recovery animal remained eight days with suspensory tissue with little pressure to diminish edema, protect against dirtiness and insects. The Heifer don't have any significant edema in surgery, no infection in suture and nule reaction with bovine pericardium graft. With fifteen days the skin points were taken of. Regarding clinical response to treatment and rapid recovery, by immediate surgery and pos-operative care, the animal returning to routine of production system with 5 days.

Conclusions: Efficient surgery without contamination is important to avoid umbilical hernia recidive. In animals with thin abdominal wall is important use any graft in hernioplasty. Bovine pericardium graft is good option to use because is very resistant, cheaper and no rejection in bovines.

A case study of the hindlimb amputation in a Holstein cow

Reiichiro Sato¹, Kazuhiro Kawai¹, Yasuhiro Shinozuka¹, Ken Onda¹

¹Veterinary Medicine, Azabu University, Sagamihara, Kanagawa, Japan

Objectives: A Leg amputation is a localized treatment that is effective and appropriate as remedial or palliative treatment for external trauma or malignant tumours such as osteosarcoma and mastocytoma, as well

as congenital deformities. However, in cows, this procedure has rarely been performed because of factors such as the feeding environment and economic viewpoint. In the present case, we performed amputation in a cow with an open fracture in the tibia while she was in the midterm of her pregnancy. We maintained her pregnancy until the last term, and she progressed until delivery of the calf by caesarean procedure.

Materials and Methods: The subject was a 30-month-old Holstein cow raised in a dairy farm in the Kanagawa prefecture experiencing her first pregnancy. She was pushed by another cow during free-range feeding and fell down, and it was found that the inside of her lower left limb was injured and bleeding. Because her condition gradually worsened even with continued antibiotic therapy, she was admitted to the Azabu University Animal Hospital for diagnosis and treatment. At the time of admission, her weight was 430 kg; she was 5 months pregnant and unable to stand. Her left lower hindlimb moved abnormally, and we found an open wound in the inner portion of her left lower hindlimb. The fracture was examined by palpation, and was diagnosed as an oblique fracture of the left tibia on radiography.

Results: Because of the position of the fracture and the cow's weight, it was judged that repositioning by external fixation as well as internal fixation would be difficult. We performed the amputation procedure on the day after delivery in order to maintain her pregnancy. The distal end of the fractured tibia was severed at the point of the fracture, and the proximal end was removed from the femur at the knee joint. We covered the surface of the femoral block with the surrounding muscle tissue. Subsequently, we closed the subcutaneous tissue and skin in the usual manner. Postoperatively, we continued antibiotic treatment for several days to prevent infection. It was difficult for the cow to stand on her own immediately after the surgery, but from the following day, she was able to stand with the aid of a cow lift. Gradually, the amount of time she was able to stand increased. Approximately 3 weeks after the amputation, she was able to stand on her own. However, after the 10th week, the amount of time she was lying down increased. From the 12th week onwards, she once again was unable to stand. Because of her deteriorating condition indicated by the inability to stand, we delivered her calf by caesarean procedure as she entered the 9th month of her term.

Conclusions: In the present case, worsening of the overall condition was slight, and no other injuries were found apart from the tibial fracture; therefore, we performed amputation with the goal of maintaining the pregnancy. At approximately 3 weeks after the operation, it was necessary to assist the subject in standing up. However, after some time, she was able to stand on her own. Therefore, use of the amputation procedure may be possible in cows if their weight is relatively less and if they are in the mid-to-last term of their pregnancy, as in the present case.

Middle line laparotomy in calf with trichobezoar in rumen

Gertrud Elisa Campos Edler¹; Luis O. Lopes²; Marina G. M. G. Andrade²; Otavio H. S. Martins³; Diego A. D. S. Oliveira³

¹Veterinary Clinic and Surgery - Veterinary Clinical Center, ²Adjunct Professor - Department of Clinics and Surgery Veterinary Medicine School, ³Graduate Studentery - Department of Clinics and Surgery, Veterinary Medicine School, UNIPAM, Patos de Minas, Brazil

Objectives: This study aims to describe surgical approach of exploratory laparotomy, followed by rumenotomy in calf for removal trichobezoar located in rumen. The calf has 75 days and arrived in veterinary clinical center of UNIPAM with depression, acute abdominal pain and milking disinterest in last 5 hours.

Materials and Methods: Anamnese animal had tachycardia, tachypnea and slightly tympanic rumen. Hematology analysis had low hematocrit 16.89% and thrombocytopenia 85000 / mm³. Abdominal x-ray was performed in positions lateral and ventro-dorsal and observed a rounded mass in rumen region. Exploratory laparotomy was did to remove the mass and check if have another foreign body. For surgical procedure the animal was sedated with 2 mg / kg ketamine and 0.1 mg / kg xylazine. Anesthesia was maintained with isoflurane, fluid therapy with Ringer lactate and performed blood transfusion 1000 ml. Exploratory laparotomy was in midline incision 8 cm after xiphoid process and 5 cm caudal to umbilicus. Just was identified foreign body in rumen. Rumenotomy was remove trichobezoar about 8 cm of diameter, that was occupying all rumen. The rumen was closed wired polyglycolic acid number 0. Suture was performed in two plans simply continues and another invaginating, Cushing. It was subsequently washed with solution prepare with 1 l of sodium chloride 0.9% plus dimethylsulfoxide 10 mL and plus 4000 mg amikaciana. This solution was placed intraperitoneal too before midline closure. The middle line was closed with polypropylene number 2 wire at cross mattress suture. The skin suture was performed with nylon number 0, intercalating horizontal and vertical separate mattress points. For pain control was administered 1.1 mg / kg of flunixin meglumine every 24 hours during 3 days. And antibiotic therapy with ceftiofur 2.2 mg / kg every 24 hours for 10 days and 4.4 mg gentamicin / kg every 12 hours during 3 days.

Results: Animal returned anesthesia without abdominal pain and go back to milking and feed in 3 hours after surgery. In 48 hours the calf is milking the same volume as before problem. The animal remained eight days with suspensory tissue with little pressure to diminish edema, protect against dirtiness and insects. With fifteen days the skin points were taken of. Regarding clinical response to treatment and rapid recovery, by immediate surgery and pos-operative care, the animal returning to routine of production system with 15 days.

Conclusions: The solution with antibiotic placed intraperitoneal and suspensory tissue is helpful to pos-operative success. But most importante to avoid animal death is perform rapid diagnosis and immediate surgery to remove trichobezoar.

Operative treatment of abdominal wall hernia in a newborn Simmental calf

Muharrem EROL¹; Ali Cesur Onmaz²; Gultekin ATALAN³; Hanifi EROL³; Zafer DOGAN³

¹Surgery, Balikesir University, Veterinary Faculty, Balikesir, ²Internal Medicine, ³Surgery, Erciyes University, Veterinary Faculty, Kayseri, Turkey

Objectives: The purpose of this study was to investigate an unusual case of abdominal wall hernia in a newborn calf. A one-week-old Simmental calf was admitted to the Large Animal Hospital of the Veterinary Faculty of Erciyes University with a story of an abnormal body posture that involves the entire abdomen.

Materials and Methods: The detailed examination began with observations of the calf from a distance and is followed by a physical examination of the abdomen to assess the developing abdominal hernia. Additionally, blood samples were collected from jugular vein of newborn calf for hematology and blood gas analysis. Abdominal ultrasound was used to look at organs in the abdomen, including the liver, gallbladder, spleen, pancreas, kidneys and intestines. Radiography was performed in a latero-lateral position of the patient.

Results: In this case, a lateral hernia due to a weakness or defects in the fibromuscular tissue (fascia and muscle) of the right abdominal wall, resulting in a protrusion of abdominal contents, was diagnosed by physical examination. It caused a noticeable bulging, while all the other clinical and laboratory parameters remained unchanged. Localization of the abdominal wall defect was confirmed with abdominal ultrasonography and radiography. Because the bulge could not be reduced, surgical repair was decided. A polypropylene mesh sack of 15 x 15 cm is sewn around the abdominal wall hernia on the right side.

Conclusions: After surgical intervention, the intestines or other abdominal organs were not damaged and the newborn calf did not show any signs of digestion problems. This case indicates that abdominal wall hernia resulting from defects in calves can be surgically treated successfully.

General Inhalational Anesthesia due to Emergency Ventral Hernia Surgery in Calf

Michał Trela¹Katarzyna Siewruk²Barbara Lisowska³Michał Dabrowski¹Ricardo Faundez⁴Bartosz Pawlinski¹Zdzisław Gajewski⁵

¹Dep. for Animal Reproduction, WCB, CBB, ²Departament for Animal Reproduction, FVM, Warsaw University of Life Sciences, ³Anesthesiology and Intensive Care Department, Independent Public Hospital them. Prof. Adam Gruca CMPK in Otwock., ⁴Dep. for Animal Reproduction, FVM, Warsaw University of Life Sciences, ⁵Dep. of Animal Reprod, CBB, WCB, Warsaw University of Life Sciences, Warsaw, Poland

Objectives: General anesthesia is rarely carried out in these species especially in calves because of susceptibility to complications associated with recumbency and anesthesia: regurgitation, tympani, hypoxia, apnea, aspiration pneumonia and trauma as well. The most common surgical procedures are undertaken using paravertebral nerve block or local infiltration anaesthesia.

Materials and Methods: Three weeks old calf was brought to the Large Animal Clinic suffers from severe abdominal pain, apathy and lack of appetite and urination with large evident abdominal wall deformation. The clinical examination was done. The body temperature was increased up to 40,0° C, HR 130/min, BR 45/min and severe abdominal pain was confirmed especially near the abdominal wall deformation, which was swollen, hot and hard to palpate. Ultrasound examination of the abdomen was performed. The ventral hernia was diagnosed with large intestine section presence inside hernia sac. The general inhalational anesthesia (sevoflurane in oxygen; Sevoflurane Baxter) with endotracheal intubation following intramuscular premedication (medetomidine 0,002 mg/kg; Cepetor 1mg/ml CP-Pharma Germany, ketamine 0,5 mg/kg Bioketan 50 ml Vetoquinol Biowet PL) and intravenous induction (propofol 5mg/kg; Scanofol 10mg/ml ScanVet Poland) was performed due to hernia surgery. The ventral hernia was removed including bowel part resection.

Supportive therapy includes patient positioning, fluid administration and continuous monitoring techniques was applied from pharmacological sedation until full the very fast recovery. The postoperative antibiotic (penicillin with dihydrostreptomycin; Shotapen Virbac; 1ml/10 kg) in combination with non-steroidal anti-inflammatory drug (flunixin 2,2 mg/kg; Flunimeg Scanvet Poland) was administrated for 5 following days.

Results: The maintenance of general anaesthesia (sevoflurane in oxygene) was smooth and easier to control compared with general anaesthesia maintenance with isoflurane in oxygene. No complications like heart arrhythmias, respiratory depression and anaphylactic reaction were observed during surgery. The recovery process after endotracheal tube removal was much faster (5 min- standing position) without complication in intensive care room for large animals compared with recovery proces after isoflurane administration (15 min). The back to consciousness after sevoflurane anaesthesia is faster than after isoflurane anaesthesia which is preferably especially in ruminants. After sutures removal it returns to the farm.

Conclusions: General inhalational anesthesia (sevoflurane in oxygene) allows for optimal however safely, painless management of the emergency surgeries in calves. Furthermore, the medical sciences state of art progress affords application of the latest anaesthetic drugs and techniques allowing to minimize anaesthetic risk, pain and distress of the animals in particular with poor clinical status. Sevoflurane is suitable inhalation anesthetic for use in calves especially for emergency however present cost is limiting factor for its use in food animals at regular base.

P04-004-198

One-step laparoscopy for correction of the left abomasal displacement in high-yield Holstein dairy cows in Brazil

Joao H. Perotta¹Rudiger D. Ollhoff²Julio A. N. Lisboa³Peterson T. Dornbusch¹Nilton Vieira⁴Ivan R. Barros Filho¹

¹Veterinary Medicine, Federal University of Parana, ²Parana State Catholic University, Curitiba, ³Londrina State University, Londrina, ⁴Bovine practioner, Arapoti PR, Brazil

Objectives: Surgical procedures for correction of abomasal displacement have been one of the most frequently performed in dairy cows, with many surgical techniques described for treatment since the first disease cases in the 1950s. Although with no report to date in Brazil, the one-step laparoscopy technique has associated advantages of traditional technique, such as abdomen visualization, with minor trauma of minimally invasive techniques.

Materials and Methods: Accordingly, one-step laparoscopy seconding Christiansen and Barisani was applied to 21 high yield dairy Holstein Friesian cows from two dairy region of Parana State with left abomasal displacement. In cows heavier than 700 Kg, a third access, over the 10° or 11° intercostal space, 15cm ventrally of second access, has been used to introduce the working channel and the big needle, because the device could not reach the right paramedian side in large cows. Short-term efficacy (during one month) of one-step laparoscopy abomasopexy has been evaluated. The surgeries have been occurred between April/2014 to April/2015. The diagnosis of LDA has been established through clinical examination in addition to the presence of scant and diarrhetic faeces, dehydration and tympanic and metallic ping on auscultation-percussion in the left para-lumbar fossa

Results: Overall, mean duration of surgery was (without animal's preparation) 35.04 ± 11.40 minutes (range, 20 to 60 minutes). Three animals underwent the Barisani (2004) technique. However, some complications were found, as exteriorization of only on toggle thread at the moment of right paramedian perforation and toggle bar suture lodged subcutaneously. Furthermore, impaired thread sliding off the trocar occurred because of friction between knot joining threads and big needle. Therefore, the surgery method has been changed to Christiansen (2004) technique. In 12/21 (57.14%) cows, this technique was performed with no complications. Ruminal (four animals), abomasal (two animals), both (one animal) and spleen (one animal) perforations occurred during surgery procedure but without post-operative intercurrentence. One cow has been showed pyloric obstruction caused by toggle bar suture, but early removal restored abomasal flux. Three animals died in consequence of different causes. One cow has showed recurrence of displacement on month following surgery. Third access was efficient in correct abomasal displacement in cows heavier than 700Kg.

Conclusions: One-step laparoscopy abomasopexy proved to be efficient in correcting LDA under field conditions. Complications found were also reported in the literature, although they have not interfered in operation efficiency. Despite the equipment price, the possibility of carrying out a procedure faster, safer and less traumatic for the cow are strong arguments for the adoption of the technique by the bovine practitioner.

P02-002-207

Analysis of bovine production dynamics related to soybean, sugar cane and corn production in Brazil

Rebecca L. A. Maranhão¹ Renato F. Guimarães¹ Osmar A. D. Carvalho Júnior¹ Paulo Ricardo M. Lima¹ Vanessa Peripolli¹ Candice B. Tanure¹ Luiza Seixas¹ Concepta McManus¹

¹University of Brasilia, Brasilia, Brazil

Objectives: The objective of this study was to analyze the spatial-temporal dynamic in Brazil's cattle production during the period from 1978 to 2012 related to soybean, sugar cane and corn production national. In addition, we analyzed the substitution and association processes between these systems using correlation analysis between the temporal series of production.

Materials and Methods: In the present study were considered Municipal production data of the effective cattle herd in period between 1978 to 2012 and the amount produced in tons of soybean, sugar cane and corn from 1993 to 2012, both acquired from Brazilian Institute of Geography and Statistics web page. Temporal series were used to calculate growth and acceleration rates for each production, as well as the direction tendencies and inverse correlations between the soy and beef production, as also the sugar cane and beef production in Brazil. The production data was organized in a table and spacialized on map of Brazil from ArcGIS® program.

Results: The results showed high growth rate and acceleration of soybean and corn production in the South, Midwest and the western of the Northeast region, with a tendency of these productions moving to the northeast of the country. The South-Central region achieved high growth rates and acceleration of sugarcane production, also was observed the displacement of sugarcane production from the Northeast region to the South-Central region, indicating the loss of participation in the Northeast over the analysis period. Meanwhile, in the recent period from 2003 to 2012, the cattle production showed high growth rate and acceleration of production in the Legal Amazon area. The inverse correlation between cattle production and sugarcane production from 2002 to 2012 was seen in municipalities in the South-Central region. Moreover, most of the municipalities that showed an increase in sugarcane production and decreased in cattle production were in this region. The inverse correlation between the production of soy and beef production was seen mainly in municipalities in the Midwest, Southeast and South. The entry of flex-fuel cars in the Brazilian market in 2003 and the rise of commodity prices in the international market can explain the recent decline in beef production in the Midwest, South, Southeast, led by increased production of soybean and sugarcane in those regions, shifting beef production to areas further north. The causes of displacement of these productions are complex, which may be linked to climatic, topograph, access to credit and technical assistance as well as market issues.

Conclusions: The methodology used was efficient in multi-temporal analysis of sugarcane, corn, soybean and cattle production, promoting the understanding of the dynamics of the productions in Brazil, which can be used as a subsidy to public policies. Long-term public policies are necessary to understand these dynamics in an integrated management to generate improvements toward sustainable practices intensification of land use, taking into account regional disparities and promoting science and innovation in Brazilian agriculture.

Regional Changes in Brazilian Beef Cattle Production

Concepta Mcmanus¹ Júlio Otávio J. Barcellos² Potira M. Hermuche¹ Osmar A. D. Carvalho Júnior¹ Renato F. Guimarães¹ Miguelangelo Gianezini² Eduardo A. Dias² Vinicius D. N. Lampert³ Danielle Zago² Paulo Ricardo M. Lima¹ Vanessa Peripolli¹ Candice B. Tanure¹ Luiza Seixas¹

¹University of Brasilia, Brasilia, ²Federal University of Rio Grande do Sul, Porto Alegre, ³Embrapa South Livestock, Bagé, Brazil

Objectives: The objective of this study was to analyze the dynamics of cattle production in Brazil on a municipal scale and to identify potential areas of strangulation for continued growth and variables that could limit the increase in production and productivity.

Materials and Methods: This study considered all municipalities in five regions of Brazil (5561). Data on cattle production in Brazil were obtained from the website of the Brazilian Institute for Geography and Statistics from 1977 and 2011. The spatial midpoint of production in the country was calculated for each year to assess the direction of production in the country. Changes in the relative production and acceleration of production were calculated, and these data were spatialized using ArcGIS®. Cluster and canonical discriminant analyses were performed to further highlight differences between regions in terms of cattle production.

Results: Currently, the mean production point has moved from the Center of Minas Gerais State (in the southeast region) to the North of Goiás State (in the midwest region). These data generate a reflection of changes in environmental factors, such as pasture type, temperature and humidity. The relative increase in production in the midwest and northern regions is evident, which is considerably higher compared to other regions. In the northern region, because the original herd was small, the initial acceleration (1980-1990) was high with the migration of cattle production from other regions, but in numeric terms, the herd size has only become expressive within the last 10 years. Recently, "traditional" cattle-rearing regions, such as the south and southeast, showed a reduction in growth rates as well as a reduction in herd size or internal migration over the period studied. Regardless of the slowing growth and significant reduction in herd numbers, the states of São Paulo, Minas Gerais, Mato Grosso do Sul, Mato Grosso and Goiás, still represent the majority of beef exports in Brazil. These states are where the main structure for export of slaughtered animals is located, and they are also the main centers for completing feed-lots, which explains the fact that even with a reduction of the herd, they remain the leading exporters of meat. However, with the technological improvements in the agricultural sector, soils that are currently limited for farming should, in the future, present economic viability and force livestock production to new regions of the country.

Conclusions: Changing the configuration of a production system for beef cattle production from one region to another requires skills and expertise as it passes through a redefinition of farming objectives, as well as strategies and processes to achieve better results. Future studies should incorporate variables related to the expansion of crops, income from plant products, average area of farms, different specializations in cow-calf, growth and completion of production systems and density of cattle in different regions of Brazil.

P02-002-210

Nitrogen Efficiency as weak Point analyze in organic dairy farming

Hendrik Sommer^{1,*}

¹ESCON, 35066 Frankenberg (Eder), Germany

Objectives: The aim of the current study is to clarify how weak points analyze of nitrogen cycles in organic dairy farms enables farm managers to identify the points in the farm nutrient cycle at which nitrogen leaching is most critical.

Materials and Methods: The subject of the investigation is of the Educational and Research Farm at the Justus-Liebig-University Gießen, Gladbacherhof. The investigation period was from 1993 to 2006. The corresponding data basis were the farm accountancy, the Acreage index, the milk recording data, feed analyzes and yield. Different nutrient cycle system levels have been observed. Every level was analyzed by special nutrient balances. The efficiency is expressed as Input:Output-ratio in percent. If one level has an input of 100 units nitrogen and an usable output of 50 units nitrogen it means an N efficiency of 50 %. Based on a top down decision tree the weak points were systematically identified.

Results: Based on the farm gate balance a nitrogen efficiency of 53 % in the average of three years was observed. In the next step the livestock level was analyzed. The nitrogen efficiency on the dairy production level (feedstuff input to the stable vs. milk,meat and pasture output) amounted 98 %. So this level was excluded as weak point in this farm system. The analyze of the cropland and grassland balance confirmed a nitrogen efficiency of 75 % on grassland, but only 49 % on the cropland. While at the dairy production the nitrogen utilisation is very good, the success stayed on the cropland off yet. The low nitrogen efficiency of only 49 % is associated with a lost amount of reactive nitrogen.

Conclusions: In the present study it can be resumed that weak points analyze is able to identify critical points in the nitrogen cycle of a farm system. The analyse has to go on ...deeper“ levels of the nutrient cycle.

Therapeutics & Pharmacology

P04-004-106

Brucellosis in buffaloes: A novel treatment approach using chemo-immunotherapyHaisem U. Rasool¹Muhammad Avais¹Muhammad S. Khan¹Masood Rabbani²Khushi Muhammad³

¹Department of Clinical Medicine and Surgery, University of Veterinary and Animal Sciences, Lahore, Pakistan, ²University Diagnostic Laboratory, University of Veterinary and Animal Sciences, Lahore, Pakistan, ³Department of Microbiology, University of Veterinary and Animal Sciences, Lahore, Pakistan, Lahore, Pakistan

Objectives: Brucellosis in cattle and buffaloes is caused by *Brucella abortus* and characterized by late term abortions, placentitis, retained placenta, still birth, orchitis and infertility imposing colossal economic losses to the dairy industry. It is a zoonotic problem that need to develop an effective treatment/control strategy. Therefore present study was carried out to evaluate a novel treatment approach for brucellosis in buffaloes using chemo-immunotherapeutic agents.

Materials and Methods: Experimental study included healthy (A and B groups) and brucellosis positive (C and D groups) buffaloes. Each of the group A, B, C and D contained 5 animals. The animals in both the groups A and C were given 1) four injections of long acting oxytetracycline (20mg/kg body weight; BW) intramuscularly (IM) repeated after every 48 hours, 2) five consecutive injections of streptomycin (13mg/kg BW IM), 3) three consecutive injections of flunixin meglumine (2mg/kg BW IM) for three days followed by five injections (IM) of selevit for five consecutive days and 4) combined vaccine (oil based chemically inactivated FMD virus and live attenuated rough strain of *B. abortus* RB51). Each animal of group B and D served as negative and positive control, respectively. Effectiveness of a particular treatment protocol was evaluated on the basis of antibody titer (RBPT and ELISA) and antigen detection thorough PCR. Moreover, birth weight and placenta dropping time in forthcoming parturition of the animals was also recorded

Results: Each animal of the treated groups were negative to enzyme linked immunosorbent assay (ELISA) on six months post-treatment and polymerase chain reaction (PCR) on subsequent parturition. On screening through RBPT and ELISA, the treated and immunized animals showed increase in ELISA antibody titer against *B. abortus* for certain period of time but subsequently became negative. Antigens of the pathogenic *B. abortus* inactivated either by antibiotics or gamma interferon activated macrophages in the presence of their specific memory B cells may be responsible for mounting the ELISA or RBPT antibody titer and declining thereafter on clearance of the *Brucella* specific antigen from the host body. On subsequent parturition, the birth weight of calves and placenta dropping time were non-significantly different ($P>0.05$) in brucellosis negative buffaloes and buffaloes recovered from brucellosis in response to treatment

Conclusions: From the results of this study it was concluded that use of oxytetracycline in combination with streptomycin, flunixin meglumine, vitamin E + selenium followed by oil based FMD and RB51 vaccines (chemo-immunotherapy) is an effective way to treat *Brucella* infected buffaloes in local circumstances.

Comments: Brucellosis is serious problem to dairy herds in Pakistan and it is almost impossible to implement test and slaughter policy due to poor economic status of the farmers. Therefore, an attempt was made to treat brucellosis, which showed promising results.

Therapeutics & Pharmacology

P04-004-107

Blood Electrolytes Of The Calves Treated To Neonatal Diarrhea With Fast Action Enrofloxacin And Oral Electrolyte And Energy ReplacementViviane R. Rabassa¹Ismael M. Cavazini¹Luis Gustavo C. da Silva²Alexandre Bilhalva¹Camila Pizoni¹Rubens A. Pereira¹Augusto Schneider¹Eduardo Schmitt¹Marcio N. Corrêa¹ and Center for Research, Teaching and Extension in Animal Science (NUPEEC)

¹Federal University of Pelotas, Pelotas, ²Universidade da Região da Campanha, Alegrete, Brazil

Objectives: The aim of the study was to evaluate the effect of the therapeutic strategies for the treatment of neonatal diarrhea using the fast action enrofloxacin and its association with oral electrolyte and energy replacement on blood electrolytes (sodium and potassium) of the Holstein calves.

Materials and Methods: This study was conducted in a commercial farm located in southern Rio Grande do Sul - RS - Brazil (32.8 ° 16 'S, 52.8 ° 32'L). Were used 24 Holstein calves, monitored from birth to sixth week of life. During the experimental period were performed clinical tests twice weekly on all animals. After showing diarrhea clinical signs, the calves were randomly assigned to the treatments: Control Group, with animals remained healthy (CONT; n = 6); Group Antibiotic (ATB; n = 4) Group Antibiotic + Intravenous support (ATB + IS; n = 4); Group Antibiotic + Oral support (ATB + OS; n = 7); Group Intravenous support (IS; n = 3). The active ingredient used in the groups that received antibiotics was the fast action enrofloxacin (Kinetomax®, Bayer Animal Health, Germany), a single dose of 7.5 mg/kg of body weight (BW), intramuscularly (IM). The support used in the treatment ATB + IS and IS groups consisted of oral administration of activated charcoal (6 g) once daily for 3 days, flunixin meglumine (Flunamine®, Bayer Animal Health, Germany) at a dose of 1,1 mg/kg of body weight, intramuscularly, and in cases of dehydration, intravenous fluid NaCl 0.9% based on the volume to be established according to the degree of dehydration. For ATB + OS group has been replaced by the IV fluid supplementation with oral replacement solution (Glutellac®, Bayer Animal Health, Germany) at a dose of 50 ml, added to milk, twice a day. After the diarrhea diagnostic was collected blood sampling at 0, 24, 72 and 120 h in relation to the diagnosis, to blood evaluation of the sodium and potassium.

Results: Serum sodium levels differ between groups (CONT: 206.40 ± 5.23 mmol/L; ATB: 172.44 ± 6.41 mmol/L; ATB + IS: 137.81 ± 6.41 mmol/L; IS: 181.80 ± 7.40 mmol/L; ATB + OS: 201.56 ± 4.85 mmol/L; $P<0.0001$), being the ATB + OS was the single able to maintain sodium levels similar to the CONT; the other groups differed from the CONT and ATB + OS group ($P<0.05$). Regarding the potassium levels was difference between groups (CONT: 5.12 ± 0.31 mmol/L; ATB: 5.84 ± 0.37 mmol/L; ATB + IS: 5.32 ± 0.37 mmol/L; IS: 6.18 ± 0.43 mmol/L; ATB + OS: 6.56 ± 0.28 mmol/L; $P=0.01$), being the IS and ATB + OS differed from the CONT group; the ATB + OS group also differed from ATB + IS group.

Conclusions: Thus, we conclude that treatment with fast action enrofloxacin and its association with oral electrolyte and energy replacement was effective in maintaining sodium levels avoiding hyponatremia caused by diarrhea, and increase potassium levels, due to the presence of this mineral in their composition. Since the hyperkalemia observed in untreated animals with fast action enrofloxacin and receiving only intravenous support, indicating that these animals had greater disease severity, making potassium release into the blood by acidosis and inflammation.

P04-004-108

Pulmonary lesions and clinical disease in *Histophilus somni*-challenged calves treated with, either tildipirosin or tulathromycin

Anthony W. Confer^{1,*}, Jared D. Taylor¹, Timothy A. Snider¹, Mark Spire²

¹Department of Veterinary Pathology, Oklahoma State University, Stillwater, ²Merck Animal Health, Desoto, Kansas, United States

Objectives: To determine the efficacy of tildipirosin or tulathromycin metaphylaxis during early *Histophilus somni* infection of the respiratory tract in cattle as a model for bovine respiratory disease reduction

Materials and Methods: On study day 0, 24, 4-month-old dairy steers, negative for anti-*H. somni* antibodies and BVDV, were injected subcutaneously as follows: Group 1- Tildipirosin at 4 mg/kg; Group 2-Tulathromycin at 2.5 mg/kg; Group 3-NaCl, 1 mL isotonic saline/45.4 kg. Immediately after treatment, all were inoculated intrabronchially with 7.0 x 10⁹ CFU virulent *H. somni* strain 7735, which is susceptible to both antibiotics. Body weights, rectal temperatures, and clinical evaluations (0-9 total score) were recorded for time 0, 12 hours after inoculation, twice daily on days 1 and 2 and morning of day 3. On day 3, all animals, were sedated and humanely euthanized. At necropsy, lungs were weighed, percent pneumonia recorded, and tissue submitted for histopathology and bacterial isolation. Lung histopathology (LHS) and necrosis scores were determined for each lung. Statistical comparisons of clinical scores, rectal temperature, lung scores, and histopathology scores were analyzed by either non-parametric or general linear model methods.

Results: After challenge, weight losses per group were not statistically different (p=0.98). By 8 h, rectal temperatures and clinical scores increased from time 0 for each group (p<0.05), and increases were not significantly different among treatment groups (p>0.05). At necropsy, lung weight as a percentage of body weight was significantly higher for saline-treated than for tildipirosin-treated calves (p<0.01); however, there were no significant differences between the two macrolide-treated groups (p=0.50) or between tulathromycin- and saline-treated calves (p=0.34). Lung lesions varied from multifocal to diffuse, red and gray consolidation with or without obvious foci of necrosis. Fibrinous pleuritis was present in severely affected lungs. Percent lung consolidation ranged from a mean of 5.6%, 8.6%, or 18.2% among the tildipirosin-, tulathromycin-, or saline-treated groups, respectively. Percent lung consolidation in tildipirosin-treated calves were significantly lower than in saline-treated calves (p<0.02). There were no significant differences between the two groups of macrolide-treated calves (p=0.89) or between tulathromycin- and saline-treated calves (p=0.25). Histopathology showed , right lung lesions, necrosis, and LHS scores were significantly lower (p<0.05) for tildipirosin and for tulathromycin treatment compared to control. Necrosis was not found in any macrolide-treated lung. Bacterial isolation scores were significantly higher for the control than for tildipirosin and tulathromycin -treated (p<0.05) calves. *H. somni* was not isolated from tildipirosin-treated calves.

Conclusions: At necropsy, tildipirosin-treated calves had less lung consolidation and lowest relative lung weights than control calves. Histopathology scores of inflammatory changes were not significantly different for tildipirosin- and tulathromycin-treated calves. In the present study, necrosis was completely absent in lungs from macrolide-treated cattle. The significance of absence or reduced lung necrosis prevents the formation of scar tissue and allows the airways to be repaired through reepithelization. Thus, if necrosis can be avoided or reduced through macrolide treatment, this improves animal performance and welfare.

Therapeutics & Pharmacology

P04-004-109

Effects of tilmicosin on bovine neutrophil and lymphocyte functions

Hidetoshi Higuchi^{1,*}, Satoshi Gondaira¹, Hidetomo Iwano², Kazuhiro Matsui³, Hajime Nagahata¹

¹Animal Health Lab., ²Veterinary Biochemistry, Rakuno Gakuen University, Ebetsu, Hokkaido, ³Elanco Animal Health, Kobe, Japan

Objectives: *Mycoplasma* species are highly contagious pathogens that cause mastitis, otitis media, arthritis, and pneumonia. As there is no effective vaccine against *Mycoplasma* infection, control depends on good husbandry and antibiotic therapy. Tilmicosin is a macrolide antibiotic used to control *Mycoplasma* infection. Macrolide antibiotics have recently been reported to modulate the immune system. However, the effects of tilmicosin on the bovine immune system have not been clarified. We examined the effects of tilmicosin on bovine neutrophil and lymphocyte functions for *Mycoplasma* eradication.

Materials and Methods: (1) Blood samples

Blood samples (30 mL each) were drawn from the jugular veins of five 3–5-year-old clinically healthy Holstein cows into heparin-containing tubes (20 IU/mL).

(2) **Isolation of neutrophils and lymphocytes:** Neutrophils and lymphocytes were isolated from heparinized blood by Ficoll-sodium iohalamate gradients (specific gravity, 1.078). The resulting cell population comprised >95% neutrophils and >98% lymphocytes, as determined by Wright-Giemsa staining; >99% of the cells were viable when assessed by trypan blue dye exclusion. Cells were treated with tilmicosin at concentrations of 0.01, 0.1, 1, 10, and 100 µg/mL.

Chemiluminescent (CL) response: 100 µL of neutrophil suspension (2 × 10⁶ cells/mL) were incubated at 37°C for 10 min in a luminometer (ATTO Co., Tokyo, Japan); 10 mL of luminol (final concentration, 10⁻⁴ M) was then added. After 5 min of equilibration, *Mycoplasma bovis* was added. The peak response and integrated value were evaluated.

(3) **Apoptosis:** 500 µL of neutrophil suspension (2 × 10⁶ cells/mL) were incubated with *M. bovis* (multiplicity infection [MOI], 100) at 37°C for 30 to 60 min. Annexin V and propidium iodide-positive cells were identified as apoptotic cells with a flow cytometer (Millipore Co., Tokyo, Japan).

(4) **Blastogenesis:** 200 µL of lymphocyte suspension (2 × 10⁶ cells/mL) and *M. bovis* (MOI, 100) were co-incubated at 37°C for 72 h. Blastogenesis was evaluated with the Cell Counting Kit 8 (Dojindo Co., Kumamoto, Japan).

Results:

1. LDCL response of neutrophils

Effects of tilmicosin on *M. bovis*-induced luminol-dependent CL (LDCL) responses of neutrophils were evaluated in lactating cows. Mean (standard deviation [SD]) *M. bovis*-induced peak CL values of neutrophils at tilmicosin concentrations of 0.01, 0.1, 1, 10 and 100 µg/mL were 162.1 (45.3), 215.5 (46.2), 254.2 (37.8), 255.4 (42.4), and 306.1 (55.9), respectively; these were significantly (p<0.01) higher than those of controls. Similarly, mean (SD) *M. bovis*-induced integrated CL values at tilmicosin concentrations of 0.01, 0.1, 1, 10, and 100 µg/mL were also significantly (p<0.01) higher than those of controls.

2. Apoptosis of neutrophils

Effects of tilmicosin on *M. bovis*-induced apoptosis of neutrophils were evaluated. Mean percentages of *M. bovis*-induced apoptosis of neutrophils at tilmicosin concentrations of 0.01, 0.1, 1, 10 and 100 µg/ml were almost the same as those of controls after 30 min of incubation. However, mean (SD) percentages of *M. bovis*-induced apoptosis of

neutrophils at tilmicosin concentrations of 0.1, 1, 10, and 100 µg/mL were significantly ($p < 0.01$) higher than those of controls after 60 min of incubation.

3. Blastogenesis of lymphocytes

Effects of tilmicosin on *M. bovis*-induced blastogenesis of lymphocytes were evaluated in lactating cows. Mean (SD) values of *M. bovis* induced-blastogenesis of lymphocytes at tilmicosin concentrations of 0.01, 0.1, 1, 10, and 100 µg/mL were 2.21 (0.23), 2.12 (0.32), 1.94 (0.42), 1.94 (0.42), and 1.82 (0.32), respectively; these were significantly ($p < 0.01$) higher than those of controls.

Conclusions: In this study, we clarified that tilmicosin enhances *M. bovis*-induced neutrophil and lymphocyte functions. Tilmicosin induces apoptosis of neutrophils stimulated with *M. bovis*. Neutrophil apoptosis provides anti-inflammatory benefits and may prevent tissue injury from the excessive inflammatory reaction caused by *M. bovis*. These results indicated that tilmicosin has therapeutic activity against *Mycoplasma* infection. We conclude that tilmicosin has not only bactericidal activity but also immunomodulatory and anti-inflammatory activity against *M. bovis*.

Pharmacokinetic evaluation of a new combination of Fipronil and Fluazuron topically administered (pour-on) in cattle.

Welber D. Z. Lopes¹, Rafael M. Chiummo², Emerson M. Botelho², Luis F. Vettorato²

¹Instituto de Patologia Tropical e Saúde Pública, Universidade Federal de Goiás, Goiânia, GO, ²MSD Saúde Animal, São Paulo, Brazil

Objectives: This study aimed to determine the pharmacokinetic parameters of a new combination of Fipronil and Fluazuron, administered to cattle via pour-on at a single dose of 1 ml / 10 kg body weight (corresponding to 1.25 mg / kg of Fipronil and 2.5 mg / kg of Fluazuron).

Materials and Methods: Eight crossbred animals of 14 to 24 months old (4 males, 4 females) were selected. Animals were not exposed to any other parasiticide at least 60 days prior to the start of the study. All animals received the combination product on day 0. A 10 mL blood sample was collected by jugular vein from all animals at time 0 (immediately before treatment) and with 3, 6, 12, 24, 48, 60 hours and 3, 4, 6, 8, 10, 12, 14, 17, 21, 28, 35 and 42 after treatment. Up to 2 hours after each collection, samples were centrifuged for 15 minutes at 1.200G. The separated plasma was placed into two siliconized Eppendorf® tubes (1.5 mL each) pre-identified and stored at -20°C until transportation to the laboratory. The analysis of Fipronil and Fluazuron were performed by liquid chromatography attached to a mass detector (LC-MS/MS). The following pharmacokinetic parameters were calculated from the plasma **Results:** elimination half-life ($T_{1/2\text{el}}$); maximum plasma concentration (C_{max}); time of maximum plasma concentration (T_{max}) and area under the curve (AUC).

Results: The Fipronil maximum concentration was 73.7 g / L (C_{max}) with 2.5 d after administration of the product (T_{max}). The $AUC_{42\text{d}}$ for Fipronil was 35699.4 µg-hr / L and the half-life ($T_{1/2}$) was between 17 and 21 d after treatment ($C_{1/2} = 36.85 \mu\text{g} / \text{L}$). For Fluazuron, the maximum concentration in the plasma was 26.1 µg / L (C_{max}) occurred after 6 days after the product was administered (T_{max}). The $AUC_{42\text{d}}$ was 10472.6 4 µg-hr / L. $T_{1/2}$ was 13.05 µg / L ($C_1 / 2$) obtained between 21-28 d after administration.

Conclusions: Given the results, it can be inferred that Fipronil showed peak concentrations (2.5 days) earlier than Fluazuron (6 days), followed by a gradual decrease of both active ingredients until the last observation day (42 days post-treatment).

Therapeutics & Pharmacology

P04-004-111

Therapeutic and residual efficacy of a novel Fluazuron combination against Rhipicephalus (Boophilus) microplus in naturally infested cattle

Welber D. Z. Lopes¹, Rafael M. Chiummo², Emerson M. Botelho², Luis F. V. Vettorato²

¹Instituto de Patologia Tropical e Saúde Pública, Universidade Federal de Goiás, Goiânia, GO, ²MSD Saúde Animal, São Paulo, Brazil

Objectives: Two experiments were conducted to evaluate the efficacy of a new formulation containing Fipronil (1.25 mg / kg) + Fluazuron (2.5 mg / kg), administered once, via pour-on, against *Rhipicephalus* (*Boophilus*) *microplus* in naturally infested cattle.

Materials and Methods: The studies were conducted in the city of Aquidauana, Mato Grosso do Sul State, Brazil (Experiment 1) and in the city of São José do Rio Pardo, São Paulo State, Brazil (Experiment 2). In both experiments, 20 animals (Holstein and Simmental, respectively) were randomized into two groups of 10 animals each (T01: treated with Fipronil + Fluazuron; T02: Saline 0.9 % Control) based on the average R. (B.) microplus counts (females with 4.5 and 8.0 mm in length present on the left side of each animal) from the three consecutive counts pre-treatment (days -3, -2 and -1). The therapeutic and residual efficacy of such formulation were assessed on days 1, 3, 7, 14, 21, 28 and weekly until 56 days post-treatment (DPT).

Results: In Experiment 1, the combination of Fipronil + Fluazuron obtained efficacy higher than 95% from the 3rd to the 35th DPT (96.26%, 100.00%, 99.58% and 97.81% respectively on days 3, 7, 14, 21, 28 and 35 post-treatment). The efficacy of such formulation remained higher than 80% until 42 DPT (88.79%).

In Experiment 2, the combination of Fipronil + Fluazuron obtained efficacy higher than 95% from the 7th to the 35th DPT (96.32%, 96.40%, 97.22%, 97.08% and 96.28% respectively on 7, 14, 21, 28 and 35 DPT). In this experiment, the residual efficacy was still higher than 90% (93.32%) at 42 DPT. In both studies, the R. (B.) microplus counts on the Fipronil + Fluazuron treated animals were significantly lower ($p \leq 0.05$) than the control animals from the 3rd to the 56th DPT.

Conclusions: Based on the results obtained in these experiments, the new combination of Fipronil + Fluazuron administered once via pour-on, showed high efficacy against *Rhipicephalus* (*Boophilus*) *microplus* in naturally infested cattle.

P04-004-112

Therapeutic and residual efficacy of a novel combination of Fipronil and Fluazuron against Rhipicephalus microplus in artificially infested cattle

Welber D. Z. Lopes^{1,*}Rafael M. Chiummo²Emerson M. Botelho²Luis F. Vettorato²

¹Instituto de Patologia Tropical e Saúde Pública , Universidade Federal de Goiás , Goiânia, GO, ²MSD Saúde Animal , São Paulo, Brazil

Objectives: The experiment was conducted to evaluate the efficacy of a new formulation containing Fipronil (1.25 mg / kg) + Fluazuron (2.5mg / kg), administered once via pour-on against Rhipicephalus (Boophilus) microplus in artificially infested cattle.

Materials and Methods: The experiment was conducted in the city of Abadia dos Dourados, Minas Gerais State, Brazil. 28 crossbreed steers were randomized into four groups of seven animals each, based on the average counts of engorged female ticks detached from each animal on three consecutive days prior to treatment (days -3, -2 and -1): T01: Association of Fipronil (1.25 mg / kg) + Fluazuron (2.5 mg / kg); T02: Fipronil standalone (1.0 mg / kg); T03: Fluazuron standalone (2.5 mg / kg); T04: Saline 0.9% Control. The therapeutic and residual efficacy against R. (B) microplus was evaluated by daily counts of all female ticks detached from each animal, from the 1st to 60th days post treatment (DPT).

Results: In this study, T01 showed mean therapeutic efficacy (1 to 23 DPT) of 95.8% while T02 and T03 presented respectively 94.0% and 89.0 %. T01 presented efficacy ≥90% from the 4th to 45th DPT, with efficacy ≥95% in 30 counting days during this period. On the other hand, T02 and T03 presented, respectively, efficacy ≥90% from the 4th to 40th DPT and from the 5th to the 39th DPT (31 and 27 counting days with efficacy higher than 95%). The efficacy of such formulations were above 80% until 57 (T01), 42 (T02) and 48 (T03) DPT. The statistical comparison showed that T01 mean counts were significantly lower (p≤0.05) than the control group counts from the 3th DPT until the end of the study (60 DPT). The animals from T02 presented statistically lower mean counts compared to the control group (p≤0.05) from 2th to 46th DPT while this difference was significant for T03 treated animals from 4th to 56th DPT.

Conclusions: Based on the results from this experiment, the new combination of Fipronil + Fluazuron administered once via pour-on, showed higher mean therapeutic efficacy and longer residual protection against Rhipicephalus (Boophilus) microplus in naturally infested cattle when compared to standalone formulations of Fipronil and Fluazuron.

Antimicrobial susceptibility of Staphylococcus aureus isolated in bovine mastitis in France

Sylvain Bareille¹Frederic Leboeuf¹Guillaume Lequeux²Jantijn Swinkels^{3,*}

¹MSD Santé Animale, Beaucauzé, ²ISAE 35, BioAgroPolis , Javené, France, ³Merck Animal Health, Madison, United States

Objectives: To determine the minimal inhibitory concentrations (MIC) of antimicrobials for Staphylococcus aureus (S. aureus) from the milk

of dairy cattle in France. Getting new data for this topic is relevant because S. aureus is one of the most frequently isolated bacteria in milk samples from sub-clinical cases of bovine mastitis in France (about 18% excluding sterile or contaminated samples). Finally, these data may help reaching a better and responsible use of antibiotics and possibly contribute to the reduction of antibiotic use in France of 25% from 2012 to 2017.

Materials and Methods: The susceptibility of 80 isolates of S. aureus to antibiotics was assessed by the standard agar dilution method. These strains were isolated using milk samples from cows affected by clinical or sub-clinical mastitis. They were chosen at random from all milk samples received in 2013 by ISAE 35 laboratory from all over France and the strains tested were epidemiologically unrelated (eg not coming from the same episode of disease or the same herd - guideline EMEA/CVMP/627/01).

A MIC-determination was performed using the agar dilution method according to the standard method (standard CLSI VET01-A4). Twelve antimicrobial agents – penicillin G, cloxacillin, nafcillin, cephalixin, cefazolin, cephapirin, cephalonium, cefquinome, amoxicillin-clavulanic acid, tylosin, gentamicin, and enrofloxacin – were investigated because they are frequently used in the field. The results are expressed in µg/mL.

Results: All S. aureus isolates were sensitive to cloxacillin, nafcillin, cefazolin, cephapirin, cephalonium and amoxicillin-clavulanic acid. Antibiotic resistant strains were observed for penicillin G (n=17, 21%), cephalixin (n=2, 3%) and cefquinome (n=2, 3%). This percentage (21%) of S. aureus strains resistant towards penicillin G is lower than the 30% mentioned in the RESAPAPH report.

The antimicrobial susceptibility of S. aureus towards the different cephalosporins varies significantly. For example, the MIC₉₀ of cephalonium is only 0.125µg/mL towards S. aureus, when MIC₉₀ of cephalixin is 4µg/mL.

There is a high and homogeneous level of antimicrobial susceptibility of S. aureus towards gentamicin (all MIC ≤ 0.25µg/mL). But, the antimicrobial susceptibility of S. aureus towards tylosin is just below the breakpoint (MIC₉₀ = 2 µg/mL). A bimodal repartition of the MIC of S. aureus strains towards tylosin was seen, as previously described in a German study, with 2 strains (3%) showing a MIC of tylosin >256 µg/mL. S. aureus resistance towards penicillins G is mainly due to the presence of the blaZ gene, coding for a β-lactamase. The blaZ gene is frequently (30%, RESAPAPH report) detected in the strains of S. aureus isolated in France. Because the difference between phenotypic resistance (MIC determination) and genetic resistance is mainly due to the inducible expression of this gene, it seems that resistance is only observed if bacteria have previously been in contact with a β-lactam.

Conclusions: This in vitro study shows that the resistance of S. aureus towards penicillin G is widely observed and the antimicrobial susceptibility of S. aureus towards the macrolides is not optimal (high MIC, and some strains are resistant towards this antibiotic group). Although in vitro MIC studies do not always predict in vivo treatment success, based on these MIC data alone, the preferred antibiotics for treatment of S. aureus are cephalonium, gentamycin, cephapirin, cloxacillin, nafcillin, cefazolin, amoxicillin-clavulanic acid.

Flunixin meglumine transdermal pour-on solution as adjunct therapy in the treatment of bovine respiratory disease in calves less than 8 weeks of ageSiddhartha Torres^{1,*} Julien Thiry¹ Vincent de Haas¹ Philippe Brianceau¹¹Merck Animal Health, Madison, United States

Objectives: Whether Bovine Respiratory Disease (BRD) causing factor is physical, environmental, or infectious, a sequence of events occurs resulting in inflammation. It is advisable that NSAID and anti-infective agents are used concurrently. Flunixin is a NSAID commonly used for the relief of pain and control of inflammation and pyrexia associated with diseases of different origin and nature. A novel 50 mg/mL flunixin transdermal (Finadyne® Transdermal) is available for cattle. The objective of the study was to demonstrate the safety and effectiveness of flunixin transdermal in the treatment of BRD in juvenile calves.

Materials and Methods: The study was conducted following the GCP guidelines. A total of 49 calves of less than 8 weeks of age, showing severe signs of respiratory disease, were randomly assigned to treatment with either the test product, flunixin transdermal, administered topically once, or the control product, carprofen, administered by injection once, on day 0. All animals received cefquinome on days 0 and 2. The animals were observed for clinical signs of disease for 6 hours post-treatment and daily for 5 consecutive days.

Results: The decrease in rectal temperature 6 hours post-treatment was greater in the flunixin group (-1.7°C) compared to the control group (-1°C). This difference was statistically significant (p<0.0001) and the superiority of the flunixin transdermal to the control was confirmed.

In the following days, rectal temperature and clinical index (depression and respiratory signs) improved similarly over time in both treatment groups.

Neither flunixin nor control had a negative influence on the health status including appetite and faecal consistency, confirming that both products are safe.

Conclusions: The new 50 mg/mL flunixin transdermal was shown to be safe and to have a strong anti-pyretic effect and anti-inflammatory properties, and makes it a very convenient and suitable adjunct therapy to anti-infective therapy used in cases of respiratory infections in juvenile calves less than 8 weeks of age.

Effect of two different bovine somatotropins on milk yield of Brazilian dairy cowsHenderson Ayres^{1,*} Marcilio Nichi² Sandro L. Viechnieski³¹MSD Animal Health, ²Department of Animal Reproduction of USP, Sao Paulo, ³Star-Milk Farm, Céu Azul, Brazil

Objectives: Bovine somatotropin (bST) is recognized as a stimulus for increased milk production. The objective of this trial was to evaluate milk yield in a high-producing dairy cattle herd in response to two commercial sources of bovine somatotropin (bST) administered every 14 days

totalizing 16 applications. Our hypothesis was that the use of Boostin promotes greater milk production compared to Lactotropin.

Materials and Methods: Eighty Holstein cows from a commercial farm located in the south region of Brazil, averaging 1.76 ± 1.16 lactations, 77.1 ± 21.9 days in milk (DIM) and 37.5 ± 6.5 kg/d of milk were randomly assigned to one of 2 treatment groups using milk production during the 7-day pretreatment period as the blocking criterion. Treatments consisted of 16 consecutive subcutaneous injections of 500 mg of bST (Boostin, MSD Saúde Animal, Brazil) or 500 mg of bST (Lactotropin, Elanco Saúde Animal, Brazil), both administered at a 14-day interval. All cows were milked 3 times a day and received the same total mixed feed 5 times daily, consisting of corn silage, ryegrass silage, corn grain ground, soybean meal, whole cottonseed, soybean hulls, urea, minerals, and vitamins. Cows were housed in free stalls. Data were analyzed with the SAS procedure mixed with a model containing the continuous effect of the covariate and the fixed effects of block, treatment, day, number of administrations and the interaction between treatment and day and treatment and number of applications. Data were compared considering each cycle of administration for two procedures: milk yield and relative milk yield. Relative milk yield was defined as the increased milk yield from each day after administration of bST relative to the production of one day before each administration.

Results: The results show that mean square of cow nested within treatment was used as the error term to test the treatment effect. Boostin-treated cows yielded 1.78 kg/day (P = 0.02) or 1.05 times (P < 0.01) more milk than Lactotropin-treated cows; (milk yield – 39.08 ± 0.12 versus 37.30 ± 0.12 kg/d; relative milk yield – 1.09 ± 0.001 versus 1.04 ± 0.001 times, respectively). Treatment * day interaction was also an important source of variation (P < 0.01). Further, the curves pattern was similar in both graphs.

Conclusions: Our hypothesis proved to be correct. In this trial we observed statistical differences in the milk yield response when comparing both commercial sources of bST. Boostin-treated cows yielded significantly more milk than Lactotropin-treated cows.

Therapeutics & Pharmacology

P04-004-116

Efficacy of injectable florfenicol plus flunixin combination against an experimentally induced Mycoplasma bovis infection in calvesJulien Thiry¹ Sophie Rubion² Cliff Ramage³ David Reddick³ Vincent de Haas¹ Siddhartha Torres^{1,*}¹Merck Animal Health, Madison, United States, ²MSD Animal Health Innovation, Beaucauzé, France, ³Moredun Scientific Ltd, Penicuik, United Kingdom

Objectives: The objective of this blinded, randomised study was to demonstrate the efficacy of a combination of florfenicol and flunixin (Resflor®), against an experimental Mycoplasma bovis challenge in calves, in comparison to a negative control saline and a positive control tulathromycin associated with flunixin.

Materials and Methods: A total of 230 calves between 4 and 8 weeks of age, confirmed to be M. bovis antibody and antigen negative, were challenged daily for 3 consecutive days by intratracheal deposition of 12 mL pure M. bovis culture (5.14x10⁹ cfu, European isolate 208/B01). For 4 days after challenge, calves meeting enrolment criteria (pyrexia >39.5°C and abnormal respiration and/or depressed demeanour) were

enrolled for treatment with either saline (N=21), tulathromycin plus flunixin (N=64) or florfenicol-flunixin combination (N=64). After treatment, animals were observed daily for seven days for clinical recovery (rectal temperature, respiration and demeanour). On day 7 post-treatment, animals were euthanized, lungs collected for lesions scoring and lung lavage fluid collected for *M. bovis* bacteriology.

Results: After treatment, rectal temperature values, respiration and demeanour scores significantly decreased within 24 hours post-treatment with florfenicol-flunixin combination and tulathromycin plus flunixin, while they remained high for 7 days post-treatment with saline ($p < 0.0001$). At both day 4 and day 7 post-treatment, clinical recovery with florfenicol-flunixin combination was significantly superior to saline ($p < 0.0001$) and non-inferior to tulathromycin plus flunixin. The proportion of lungs with *M. bovis* lesions was 6.6% for florfenicol-flunixin combination, 5.25% for tulathromycin plus flunixin and 19.2% for saline.

Recovery of *M. bovis* from lung fluid was significantly lower for florfenicol-flunixin combination than for saline (2.27×10^5 cfu/mL versus 1.33×10^7 cfu/mL – $p = 0.0020$) and for tulathromycin plus flunixin (2.27×10^5 cfu/mL versus 2.53×10^6 cfu/mL – $p = 0.0120$).

A significant difference in daily weight gain over the 7-day study was observed in florfenicol-flunixin combination and tulathromycin plus flunixin (mean 0.40 kg/day – $p < 0.0001$), compared to saline (0.13 kg per day – $p = 1.0000$).

Conclusions: Data from this study showed that the administration of a combination of florfenicol and flunixin (Resflor®) provided an efficient clinical and microbiological cure of *Mycoplasma bovis* pneumonia in calves.

Biochemical and blood gas alterations in buffalo whole blood stored in CPDA-1 and CPD/SAG-M bags.

Antonio H. H. Minervino¹, Osvaldo G. Nunes Neto¹, Suelen A. Ricarte¹, Thamiris S. A. Silva¹, Rejane S. Sousa², Brena P. Vinholte¹, Juliana M. Portela¹, Francisco L. C. Oliveira², Kedson A. L. Neves¹, Raimundo A. Barreto Junior³, Enrico L. Ortolani²

¹Federal University of Western Pará - UFOPA, Santarem, ²Department of Clinical Science, Faculty of Veterinary Medicine, University of Sao Paulo, Sao Paulo, ³Department of Animal Science, Federal Rural University of the Semiarid Region, Mossoro, Brazil

Objectives: The whole blood transfusion in farm animal's objective the restoration of the capacity of transport and diffusion of oxygen to the tissues in cases of significant reduction in hemoglobin, as in severe anemia or acute blood loss. Thus, it was aimed to evaluate the biochemical and blood gas analysis of buffalo whole blood stored in CPDA-1 and CPD/SAG-M bags for 42 days.

Materials and Methods: We used ten adult, male, healthy, mixed-breed buffalo, from each 900 g of whole blood were collected and subsequently stored in CPDA-1, and CPD/SAG-M bags (450 g in each bag) and kept under refrigeration at 2°C to 6°C for 42 days. Whole blood stored in plastic bags were evaluated at seven moments: D0 (immediately after collection of blood), D7 (seven days after collection), D14 (fourteen days of collection), D21 (21 days after collection), D28 (28 days of collection), D35 (35 days of collection) and D42 (42 days after collection). At those moments blood gas, biochemical (glucose, total protein, albumin, sodium, potassium, cholesterol and lactate) and microbiological parameters were

analyzed. Two-way repeated measures ANOVA was used to compare the effect of time and type of blood bag.

Results: In both blood bags, increases ($p < 0,05$) were observed in oxygen pressure (pO_2), carbon dioxide pressure (pCO_2), lactate and potassium during the storage period. The reductions ($p < 0,05$) were noticeable in the concentration of sodium, bicarbonate, glucose and the pH. Cholesterol, total protein and albumin remained unaltered. The microbiological analysis reveal contamination in two bags from the same animal, which were removed from the study. The remained 18 blood bags from nine buffalos did not present any contamination until the end of the study. The buffalo whole blood stored in CPDA-1 and CPD/SAG-M plastic bags undergoes biochemical and blood gas alterations during the storage, however it remained viable for transfusion when stored for up to 42 days at temperatures of 2 to 6 °C.

Conclusions: In general, there were no clinical importance differences in the conservation of whole blood buffalo between the two types of bags (CPDA-1 and CPD/SAG-M) evaluated, being both suitable for use in this species. Whole blood of buffalo kept refrigerated for 42 days in plastic bags did not undergo biochemical and blood gas changes that could prevent its use for blood transfusion.

Acute Phase Proteins as Predictive Markers to Diarrhea and Evaluation of Treatment with Oral Electrolyte and Energy Replacement

Marcio N. Corrêa¹, Ismael M. Cavazini¹, Luis G. C. da Silva², Josiane O. Feijó¹, Lucas Hasse¹, Uriel Londero¹, Patrícia Mattei¹, Rubens A. Pereira¹, Viviane R. Rabassa¹ and Center for Research, Teaching and Extension in Animal Science (NUPEEC)

¹Federal University of Pelotas, Pelotas, ²Universidade da Região da Campanha, Alegrete, Brazil

Objectives: The aim of the study was to evaluate the acute phase proteins levels (haptoglobin and paraoxonase) in calves as predictive markers to diarrhea occurrence and to evaluate the treatment with oral electrolyte and energy replacement.

Materials and Methods: This study was conducted in a commercial farm located in southern Rio Grande do Sul - RS - Brazil. Were used 21 Holstein calves, monitored from birth to sixth week of life. During the experimental period were performed clinical tests twice weekly on all animals. After showing diarrhea clinical signs, the calves were randomly assigned to the four groups: Healthy animals without diarrhea (Healthy; n = 6), Group Antibiotic (ATB; n = 4), Group Antibiotic + Intravenous support (ATB + IS; n = 4) and Group Antibiotic + Oral support (ATB + OS; n = 7). The active ingredient used in the groups that received antibiotics was the fast action enrofloxacin (Kinetomax®, Bayer Animal Health, Germany), a single dose of 7.5 mg/kg of body weight (BW), intramuscularly (IM). The support used in the treatment ATB + IS consisted of oral administration of activated charcoal (6 g) once daily for 3 days, flunixin meglumine (Flunamine®, Bayer Animal Health, Germany) at a dose of 1,1 mg/kg of body weight, intramuscularly, and in cases of dehydration, intravenous (IV) fluid NaCl 0.9% based on the volume to be established according to the degree of dehydration. For ATB + OS group has been replaced the IV fluid by supplementation with oral replacement solution (Glutellac®, Bayer Animal Health, Germany) at a dose of 50 ml, added to milk, twice a day. Were collected blood samples every seven days on all animals. After the diarrhea diagnostic was collected blood sampling at 0, 24, 72

and 120 h in relation to the diagnosis, to acute phase proteins evaluation (paraoxonase and haptoglobin).

Results: In the period before the disease, paraoxonase levels were lower in calves that had diarrhea (15.55 ± 1.26 U/mL) compared to healthy calves (67.29 ± 2.19 U/mL; $P < 0.0001$), and already at day -28 groups have differed as to the paraoxonase levels ($P < 0.05$). Similarly the haptoglobin levels differ between groups ($P = 0.04$), with higher values of haptoglobin in healthy animals (1.23 ± 0.08) than in animals that developed diarrhea (1.23 ± 0.14). During the 120 hours of evaluation after diagnosis of diarrhea, all groups submitted to treatment differed from healthy animals ($P < 0.0001$) in the levels of paraoxonase (Healthy: 78.50 ± 2.32 U/mL; ATB: 10.64 ± 2.84 U/mL; ATB + IS: 11.51 ± 2.84 U/mL; ATB + OS: 16.90 ± 2.15 U/mL). When comparing the treated groups, the ATB group tend to have lower values of paraoxonase in relation to ATB + OS group ($P = 0.08$). Regarding the haptoglobin levels during diarrhea there was a difference trend between groups (Healthy: 3.02 ± 0.64 ; ATB: 4.16 ± 0.78 ; ATB + IS: 4.66 ± 0.78 ; ATB + OS: 2.24 ± 0.59 ; $P = 0.06$), and ATB + OS group showed lower levels of haptoglobin than ATB ($P = 0.05$) and ATB + IS groups ($P = 0.02$).

Conclusions: Thus, the paraoxonase proved to be an important marker to predict the occurrence of diarrhea in calves, while haptoglobin need for further studies to define whether it is a good marker for this. Regarding the treatments for diarrhea, antibiotic treatment associated energy and electrolyte replacement orally showed best results in terms of inflammatory profile, indicating a lesser severity of the disease.

Pharmacokinetics and distribution in interstitial and pulmonary epithelial lining fluid of danofloxacin in ruminant and preruminant calves

Danielle A. Mzyk¹, Ronald E. Baynes¹, Marilyn Martinez², Geof W. Smith¹

¹Population Health and Pathobiology, NC State College of Veterinary Medicine - Food Animal Residue Avoidance Databank, Raleigh, NC,

²Center for Veterinary Medicine, US Food and Drug Administration, Rockville, MD, United States

Objectives: The objective of this study was compare active drug concentrations in the plasma versus different effector compartments including interstitial fluid (ISF) and pulmonary epithelial lining fluid (PELF) of healthy pre-ruminating (3-week old) and ruminating (6-month old) calves.

Materials and Methods: Eight unweaned Holstein calves, 2-3 weeks of age, weighing between 41-53 kg were classified as preruminants. Eight weaned calves, 6 months of age and weighing between 151-214 kg at time of study were classified as ruminating calves. Approximately 24 h prior to start of the study, calves were restrained for placement of an intravenous catheter and a subcutaneous tissue probe. A single subcutaneous (s.c) injection of danofloxacin (8 mg/kg) (Advocin™; Zoetis) was administered to each calf in the neck per label instructions. Blood samples were taken from the jugular vein and transferred to heparinized tubes at 0 (pretreatment), 0.25, 0.5, 1, 2, 4, 8, 12, 24, 48, 72 and 96 hours post administration and stored at -80°C until analysis. Interstitial fluid (ISF) was collected at 0 (pretreatment), 2, 4, 8, 10, 12, 24, 48, 72 and 96 h after s.c. administration. In order to determine drug concentrations in pulmonary epithelial lining fluid, multiple bronchoalveolar lavages (BAL) were performed at 2, 12 and 24 h after administration. Sterile saline (100 mL) was infused into the lungs.

Plasma, ISF and BAL fluid were analyzed by high-performance liquid chromatography (HPLC) with fluorescence detection. Estimation of the amount of PELF sampled by BAL fluid was performed using the urea dilution method. Plasma protein binding analysis was performed using ultracentrifugation. Danofloxacin concentrations were evaluated using compartmental and non-compartmental analysis.

Results: After s.c. administration, the maximum concentration in plasma (C_{max}) reached 1.7 $\mu\text{g/mL}$ for preruminant and 1.6 $\mu\text{g/mL}$ in ruminant calves and occurred at 3.1 and 1.4 h post administration respectively (T_{max}). The absorption rate constant differed significantly between the two age groups. The terminal elimination ($t_{1/2}$) was estimated as 20.36 hrs for preruminant calves and 15.31 hrs for ruminant calves. These differences were not statistically significantly different. When considered the slope from T_{max} to hour 24 rather than the terminal elimination phase, the $t_{1/2}$ estimates were ranged from 4.23 to 10.16 hrs in the preruminant calves and 4.0 to 5.44 hrs in the ruminant calves. T_{max} for ISF fluid occurred later than plasma in both groups. The area-under-curve for plasma from 0 to 96 hours (AUC_{0-96}) was not statistically significant between the two groups. Whether considering the ISF to total or free plasma danofloxacin concentrations, the ISF/Plasma concentration ratios tended to be higher in ruminant calves as compared to that seen in the preruminant calves. The maximum concentration in PELF was noted to occur at 2 hours post administration in both preruminant and ruminant calves, with estimated PELF concentrations far exceeding the concentrations seen in plasma and ISF. Greater variability in drug concentrations in PELF were seen in the preruminant calves as compared to ruminating calves. The average protein binding for danofloxacin in 3 week and 6 month old calves decreased over a linear range of 0.01 to 10 $\mu\text{g/mL}$ and averaged $32 \pm 25\%$ and $37 \pm 16\%$ respectively.

Conclusions: This study reported the pharmacokinetics of subcutaneous danofloxacin when used at the approved adult cattle dose (8 mg/kg) in 2 age groups of calves. Results demonstrate two fundamental differences included the rate of drug absorption and CL/F. Trends towards differences in V_d/F and $t_{1/2}$ were also observed. A deep or third compartment, which has not been identified in previous studies, was detected and was most evident in the ruminating calves. This contributed to age-associated differences between the relationships of ISF/plasma over time. Further studies are warranted to compare drug concentrations diseased with healthy calves.

P04-004-120

A Study To Examine The Relationship Between Uterine Pathology And Depletion Of Oxytetracycline In Plasma And Milk After Intrauterine Infusion.

Patrick J. Gorden¹, Joshua A. Ydstie¹, Michael D. Kleinhenz¹, Larry W. Wulf¹, Ronette Gehring³, Chang J. Lee², Chong Wang¹, Johann F. Coetzee^{1,2}

¹Veterinary Diagnostic and Production Animal Medicine, ²Pharmacology Analytical Support Team (PhAST), Iowa State University, Ames, ³Department of Anatomy and Physiology, Kansas State University, Manhattan, United States, ⁴Division of Food and Environmental Sciences, Wonkwang University, Iksan, Korea, Republic Of

Objectives: The objective of this study was to use highly sensitive laboratory technology to determine the plasma and milk concentrations of oxytetracycline following intrauterine infusion in post-partum dairy cows. Additionally, we hoped to determine if the variability in distribution

and elimination of oxytetracycline from the uterus to plasma and milk was associated with the degree of uterine pathology between cases of metritis as determined by uterine severity scores. Our hypothesis is that cows experiencing more severe uterine pathology will have higher plasma and milk oxytetracycline concentrations compared to less severely affected cows.

Materials and Methods: Thirty-two cows received a single treatment of 4 g of oxytetracycline via intrauterine infusion. Blood and milk samples were collected prior to intrauterine therapy and throughout the trial period of 96 h post infusion. Uterine severity scores were assigned at initiation of therapy and every 24 h throughout the remainder of the trial. Plasma and milk samples were analyzed for oxytetracycline concentrations using liquid chromatography coupled with mass spectrometry. Drug concentrations in plasma and milk were modeled using non-compartmental pharmacokinetic analysis. Maximum concentrations and time at maximum concentration for plasma and milk were calculated directly from the raw data. Area under the concentration curve was calculated using the linear trapezoidal rule with linear interpolation.

Results: Following treatment, oxytetracycline rapidly diffused to plasma and milk. The mean (\pm SEM) Cmax of oxytetracycline in plasma was 220.6 ± 31.0 ng/mL was recorded at a Tmax of 23.2 ± 1.3 h after intrauterine infusion. The mean (\pm SEM) plasma area under the curve (AUC) was 8744.8 ± 1335.6 h \times ng/mL. The mean (\pm SEM) Cmax of oxytetracycline in milk was 136.2 ± 19.1 ng/mL was recorded at a Tmax of 22.0 ± 1.8 h after intrauterine infusion. The mean (\pm SEM) milk AUC was 5962.9 ± 945.6 h \times ng/mL. Eighteen of the cows still had detectable levels of oxytetracycline in milk 4 days after intrauterine infusion. The mean (\pm SEM) milk concentration of oxytetracycline in plasma at the end of the study was 13.3 ± 4.0 ng/mL (range 0 - 102.7 ng/mL). Greater uterine pathology score at the initiation of treatment showed a significant positive correlation with higher milk oxytetracycline concentration at the second milking following treatment ($R^2 = 0.46$; $P = 0.01$), but there was no correlation between initial uterine pathology score and oxytetracycline concentration at the conclusion of the study ($R^2 = -0.06$; $P = 0.75$).

Conclusions: Intrauterine administration of oxytetracycline is considered to be an extra-label therapy in the United States. When prescribing extra-label therapy, the veterinarian is primarily responsible for specification of a withdrawal time for milk and meat to ensure the products are below established legal tolerances or target test levels. Applying the established milk withhold and published sensitivity levels of the available bulk tank residue detection kits to the milk concentrations of study cows would indicate that most cows should test negative by 96 h after oxytetracycline treatment.

Effectiveness of pegbovigrastim against naturally occurring clinical mastitis in periparturient cows and heifers in a multi-site European field study

Renee Hassfurther¹, Kristina Hacket¹, Anna-Leigh Heffron¹, Beate Schnitzler¹

¹Dairy Development R&D, Elanco, Greenfield, IN, United States

Objectives: The objective of this clinical field study was to evaluate the effectiveness of pegbovigrastim against naturally occurring mastitis in periparturient cows and heifers. This clinical efficacy study was

conducted at 35 commercial farms considered to be representative of European dairy husbandry in four countries, Hungary, Germany, Netherlands and the United Kingdom.

Materials and Methods: A total of 2561 clinically healthy periparturient dairy cows and heifers (typical European dairy breeds) were enrolled in the study after physical examination. Approximately 7 days before the anticipated date of parturition, animals received subcutaneous injections of either sterile saline (0.9% NaCl) solution (control treatment) or pegbovigrastim (contents of one syringe). Within 24 hours after parturition, each cow received a second syringe of the assigned treatment (day 0 treatment). Cows were observed at each milking for clinical signs of mastitis for the first 30 days of lactation. Clinical cases of mastitis were identified by farm or study staff at the time of milking based on abnormal appearance of the quarter (swelling, heat, pain) and/or changes in the appearance of milk (clots or flakes, watery appearance, discoloration), with or without systemic signs of disease (fever, loss of appetite).

Results: The combined multi-site study enrolled cows or heifers from 5 commercial farms in the United Kingdom, 12 in Germany, 5 in Hungary and 12 in the Netherlands. The multi-site analysis demonstrated a statistically significant ($p=0.0095$) reduction of 26% in the incidence of naturally occurring clinical mastitis in the pegbovigrastim treated group relative to the control group. From the 1230 cows enrolled in the Control group, 156 cows showed clinical signs of mastitis (13%) and in the pegbovigrastim group 1235 were enrolled and 116 cows showed signs of clinical mastitis (9%).

Conclusions: Results of this multi-site field study demonstrate pegbovigrastim is effective as an aid in a mastitis management programme, to reduce the risk of clinical mastitis in periparturient dairy cows and heifers during the first 30 days of lactation. Pegbovigrastim provides a novel approach for restoring periparturient neutrophil function to normal levels enabling a reduction in the incidence of new intramammary infections during lactation. Ultimately less cows impacted by clinical mastitis equates to less milk loss, less antimicrobial use by the dairy sector, fewer cull cows, improved animal welfare and financial benefits for the farmer.

P04-004-122

Early postpartum treatment of commercial dairy cows with nonsteroidal antiinflammatory drugs increases whole-lactation milk yield

Hans Coetzee¹, Gail Carpenter², Caroline Ylloja², Laman Mamedova², Fabian Vargas Rodriguez², Luis Mendonca², Larry Hollis², Ronette Gehring³, Barry Bradford² and <http://www.asi.k-state.edu/species/dairy/research-and-extension/dairy-metabolism/members.html>

¹Department of Veterinary Diagnostic and Production Animal Medicine, Iowa State University, Ames, Iowa, ²Department of Animal Sciences and Industry, ³Anatomy and Physiology, Kansas State University, Manhattan, KS, United States

Objectives: Previous research has shown that postpartum administration of the nonsteroidal antiinflammatory drug (NSAID) sodium salicylate can increase 305-d milk yield in older dairy cattle (parity 3 and greater). However, in this prior work, sodium salicylate was delivered to cows via the drinking water, a method that does not align well with current grouping strategies on commercial dairy farms. The objective of the current study was to replicate these results on a commercial dairy farm

with a simplified treatment protocol and to compare sodium salicylate with another NSAID, meloxicam.

Materials and Methods: Dairy cattle in their second lactation and greater ($n = 51/\text{treatment}$) were alternately assigned to 1 of 3 treatments at parturition, with treatments lasting for 3 d. Experimental treatments began 12 to 36 h after parturition and were (1) 1 placebo bolus on the first day and 3 consecutive daily drenches of sodium salicylate (125 g/cow per day; SAL); (2) 1 bolus of meloxicam (675 mg/cow) and 3 drenches of an equal volume of water (MEL); or (3) 1 placebo bolus and 3 drenches of water (CON). Blood samples were collected on the first day of treatment, immediately following the last day of treatment, and 7 d after the last day of treatment; plasma was analyzed for glucose, β -hydroxybutyrate (BHB), free fatty acids, haptoglobin, and paraoxonase. Milk production, body condition score, reproductive status, and retention in the herd were monitored for 365 d posttreatment, and effects of treatment, parity, days in milk, and interactions were evaluated in mixed effects models. Significance was declared at $P < 0.05$.

Results: Whole-lactation milk and protein yields were greater in NSAID-treated cows, although 305-d fat production was not affected. Both MEL and SAL increased daily milk production compared with CON ($P < 0.05$; 36.8, 36.3, and 32.8 \pm 2.2 kg/d, respectively). Analysis of 305-d mature-equivalent milk yield resulted in similar findings, with MEL and SAL increasing yields compared with CON (both $P < 0.03$; 11,205, 11,411, and 10,472 \pm 486 kg, respectively). We found no evidence of treatment interactions with time ($P = 0.56$), although the contrasts between NSAID treatments and CON did not become significant until 7 wk in milk. There was a significant interaction of treatment and parity for plasma glucose concentration; MEL increased plasma glucose concentrations compared with CON and SAL in older cows. Sodium salicylate decreased plasma BHB concentration compared with MEL at 7 d posttreatment, although no difference was detected immediately following treatment. Haptoglobin concentrations were elevated in SAL cows compared with CON. There was a tendency for CON cows to be removed from the herd more quickly than MEL cows (42 vs. 26% at 365 d posttreatment ($P = 0.06$)). Body condition score, concentrations of plasma free fatty acids and paraoxonase, and time to pregnancy were not affected by treatment.

Conclusions: Early-lactation treatment with NSAIDs from 2 different classes increased whole-lactation milk yield by 7 to 9%, with only a 3-d treatment window immediately post-partum. When possible, NSAID effects should be recorded throughout the entire lactation, as treatment differences may be delayed and not immediately apparent following administration, such as in the current experiment. Furthermore, the tendency for MEL to delay the mean time to removal from the herd points to a fruitful area of investigation for future research.

P04-004-123

Antibiotic susceptibility of non-viral pathogens isolated from calves with BRD.

I. Nijhoving¹, H. Kuijk¹, C.P.H. Geurts², I. Botvliet³

¹MSD Animal Health, Boxmeer, ²DAP Thewi, Tilburg, ³BVL, Diessen, Netherlands

Objectives: If Bovine Respiratory Disease (BRD) occurs, treatment of non-viral pathogens (*Mannheimia haemolytica* (*M. haemolytica*), *Pasteurella multocida* (*P. multocida*), *Mycoplasma bovis* (*M. bovis*) and *Histophilus somni* (*H. somni*)) should be effective to control damage caused by this disease. To ensure the efficacy of BRD treatment during

outbreaks, both the presence and antibiotic sensitivity of pathogenic bacteria should be determined. The objective of the study was to isolate BRD causing bacteria from veal and dairy calves during disease outbreaks and to determine their antibiotic sensitivity.

Materials and Methods: At the start of BRD outbreaks on 178 Dutch farms between March 2013 and October 2015, deep nasopharyngeal swabs (2/3 from veal calves, 1/3 from dairy calves) were taken. Calves with BRD symptoms and before treated with antibiotics were enrolled in the study. The inclusion criteria for BRD symptoms were temperature, coughing, nasal and eye discharge and position of the ears. Each symptom was scored on a scale from 0 till 3 and calves should score at least 5 points. 1103 calves were enrolled and sampled for bacteriological culture and antibiotic susceptibility testing. The samples of each outbreak were inoculated directly on blood agar and chocolate agar plates and for mycoplasma inoculation on preheated PAM and PAM+ plates. The plates were incubated under aerobic and micro aerophilic conditions. The inhibition zones of these BRD bacteria were determined using sensitivity discs (paper discs) containing doxycycline/tetracycline, erythromycin/tylosin/tilmicosin, florfenicol, trimethoprim sulfa, amoxicillin/ampicillin/penicillin, flumequin and enrofloxacin/marbofloxacin and read according to the EUCAST tables. For *M. bovis* no susceptibility testing was done, because the used method is not suitable for susceptibility testing of *M. bovis*. The choice of these antibiotic sensitivity discs is based on the Dutch formulary for prudent use of antibiotics. In the Dutch formulary for prudent use of antibiotics the classification of the groups (first, second and third choice) is based on working spectra and the effects on the selection pressure of antibiotic resistance.

Results: *M. haemolytica* was isolated in 297 samples in 104 BRD outbreaks, *M. bovis* in 403 samples in 125 BRD outbreaks, *P. multocida* in 572 samples in 159 outbreaks and *H. somni* in 2 samples in 2 outbreaks. Percentage of farms where the pathogen was isolated was 58% for *M. haemolytica*, 70% for *M. bovis*, 89% for *P. multocida* and 1% for *H. somni*. Percentage of samples, where *M. haemolytica* was isolated ($n = 104$), sensitive for an antibiotic was 12% for doxycycline/tetracycline, 70% for erythromycin/tylosin/tilmicosin, 95% for florfenicol, 80% for trimethoprim sulfa, 60% for amoxicillin/ampicillin/penicillin, 87% for flumequin and 90% for enrofloxacin/marbofloxacin. Percentage of samples, where *P. multocida* was isolated ($n = 159$), sensitive for an antibiotic was 26% for doxycycline/tetracycline, 53% for erythromycin/tylosin/tilmicosin, 98% for florfenicol, 50% for trimethoprim sulfa, 90% for amoxicillin/ampicillin/penicillin, 92% for flumequin and 95% for enrofloxacin/marbofloxacin. *H. somni* ($n = 2$) demonstrated to be 100% sensitive to all antibiotics tested.

Conclusions: Compared to previous antibiotic resistance data of *M. haemolytica* and *P. multocida*, this study shows an increase of antibiotic resistance. Antibiotic susceptibility for *M. haemolytica* and *P. multocida* showed low sensitivity for first choice antibiotics (doxycycline/tetracycline, erythromycin/tylosin/tilmicosin, and trimethoprim sulfa), but high susceptibility towards florfenicol. The increasing antibiotic resistance found in this study towards first choice antibiotics, suggests more emphasis should be put on the prevention of BRD. However, if BRD occurs, florfenicol should be considered as a first choice treatment.

Efficacy, effectiveness and efficiency of an alternative treatment protocol of bovine respiratory disease with reduced amount of antimicrobials

Guillaume Lhermie^{1,2,3,*} Alain Bousquet-Mélou^{2,4} Gilles Meyer^{2,5} Henri Seegers^{1,6} Sébastien Assié^{1,6}

¹Oniris National Veterinary School of Nantes, Nantes, ²National Veterinary School of Toulouse, Toulouse, ³Vetoquinol, Lure, ⁴UMR 1331 Toxalim, ⁵UMR 1225 IHAP, INRA, Toulouse, ⁶UMR 1300 BioEpAR, INRA, Nantes, France

Objectives: The context of prudent antibiotics use is a driver for new approaches. Considering the increased efficacy of some antibiotics on low bacterial inocula, dosage regimen could potentially be decreased when given at early stage of infection. We compared the standard regimen of marbofloxacin, a fluoroquinolone used to treat bovine respiratory disease (BRD), with a new protocol administering a fivefold reduction of the standard dose at an early stage of illness. Comparisons were made for (a) efficacy in calves experimentally infected with *Mannheimia haemolytica*, (b) effectiveness and efficiency in young bulls (YB) experiencing spontaneous pneumonia

Materials and Methods: To assess efficacy, 32 calves were intratracheally challenged with 4.10⁷ CFU of *M. haemolytica* A1. Based on an increase of their body core temperature continuously monitored with ruminal boluses, calves received either: (i) saline; (ii) 2mg/kg of marbofloxacin given 3h post challenge; or (iii) 2 or (iv) 10 mg/kg of marbofloxacin given 36h post challenge. Time course of bacterial burden at the infection site was assessed by PCR quantification on bronchoalveolar lavages. Clinical signs were daily scored during 5 days.

Thereafter, 195 YBs were randomly assigned to one of two experiment groups E2 and L10, defined by detection time of BRD (Early or Late) and marbofloxacin dosage regimen (2 or 10 mg/kg), and clinically surveyed during the first month on feed. As for calves, YBs' ruminal temperature was continuously monitored. In the E2 group, YBs with a ruminal temperature ≥40.2°C for more than 12h and presenting no or only slight signs of BRD were considered as Early detected and treated with 2 mg/kg of marbofloxacin. In the L10 group, YBs with moderate or severe clinical signs of BRD were considered as Late detected and treated with 10 mg/kg of marbofloxacin. If needed, a relapse treatment was administered. Clinical response to 1st line treatment and relapse treatment were recorded. The treatments units [amount (mg)/ Used Daily Dose (mg/kg)] for a standard YB of 300 kg at risk were calculated and summed up to determine total amount of antibiotics (TA).

Results:

Efficacy: did it work after experimental infection?

Calves in the three treated groups had lower bacterial counts within 24h after treatment and at necropsy, compared to the control group. An early treatment with 2 mg/kg of marbofloxacin lead to the elimination of *M. haemolytica* load. When treated with a 2 mg/kg of marbofloxacin at a later time, 50% of calves exhibited bacteria in their lungs. A higher regimen of 10 mg/kg allowed to obtain bacterial elimination in almost all the treated calves (85%). Animals in the 3 treated groups showed a greater clinical improvement within 24h, whatever the treatment compared to control group. At necropsy, gross lesions were rare in calves from treated groups, and moderate in calves from control group.

Effectiveness: did it work in field practice?

On YBs, 1st line treatment and relapse rates were higher in E2 (45 and 25%) vs L10 (37 and 7%). 97% and 100% of YBs treated in E2 and in L10 group were cured at the end of the study.

Efficiency: did it contribute to a more efficient use of resource in field practice?

TA was decreased by 33% and marbofloxacin amount by 63% in E2 vs L10 group. A standard YB received 173 and 471 marbofloxacin units and 54 and 9 relapse treatment units in E2 and L10 groups respectively.

Conclusions: Combination of early detection of disease with low antibiotic regimen improved efficiency of drug consumption at the herd level without affecting overall treatment effectiveness, compared to antibiotic administration at a later stage when bacterial burden is increased. Such findings evidence the feasible rationalization of antimicrobial use under field conditions, to limit its impact on public health.

Novel anti-inflammatory properties of anti-microbials: Direct induction of leukocyte apoptosis and alterations of immune mediators by tulathromycin

Andre Buret^{1,*}

¹Biological Sciences, Inflammation Research Network, University of Calgary, Calgary (AB), Canada

Objectives: Using live models of calves with pneumonia and bovine cell systems, these studies aimed at identifying novel mechanisms conferring anti-inflammatory benefits to anti-microbial compounds. The effects of tulathromycin were assessed in models where pneumonia was induced by live *Mannheimia haemolytica* or by zymosan particles, in order to distinguish direct anti-inflammatory effects from those associated with anti-microbial effects.

Materials and Methods: In keeping with the guidelines for ethical use of animals, Calves were challenged intra-tracheally with *Mannheimia haemolytica* or pro-inflammatory zymosan, and treated with vehicle or tulathromycin. Bronchoalveolar lavages were collected at 3 and 24 h post-challenge for analysis. Effects of tulathromycin were also investigated in circulating neutrophils and monocyte-derived macrophages. Data were obtained using reverse-phase High Performance Liquid Chromatography, transmission electron or fluorescent microscopy, quantitative Polymerase Chain Reaction, ELISA, and Western blotting. Results were compared using ANOVA and Tukey's test, or for data from studies in vivo, non parametric Kruskal-Wallis test.

Results: Tulathromycin reduced inflammation in the lungs, as demonstrated by post-mortem assessment of pathology and histology. Tulathromycin significantly increased (P<0.05) neutrophil apoptosis and efferocytosis (phagocytic elimination) by alveolar macrophages, and reduced pulmonary LTB₄, both in the lungs infected with live bacteria, or when inflamed with zymosan. These phenomena are known to be potent contributors to the resolution of inflammation. As the effects were reproduced in a model of sterile pneumonia induced by zymosan, the properties are independent of the anti-microbial effects of the compound. Caspase-dependent apoptosis of neutrophils and macrophages induced by tulathromycin was reproduced in vitro. We also found that tulathromycin directly reduces (P<0.05) the expression of pro-inflammatory CXCL8 (mRNA and protein) by bacterial lipopolysaccharide -stimulated neutrophils and macrophages, by inhibiting the transcription factor Nuclear Factor kappa B. These effects were independent of caspase activation, which indicates that they are separate from the pro-apoptotic benefits induced by the antibiotic. Inhibition (P<0.05) of pro-inflammatory Leukotriene B₄ synthesis in neutrophils induced by tulathromycin was caused by blockage (P<0.05) of pro-inflammatory phospholipases

(PLD and PLA₂). In contrast, Tulathromycin directly increases ($P < 0.05$) the synthesis of pro-resolution Lipoxin A₄, in resting and in Calcium²⁺ ionophore-activated neutrophils.

Conclusions: The findings illustrate novel mechanisms through which an anti-microbial compound such as tulathromycin may inhibit pro-inflammatory events and promote resolution of inflammation in the infected lung. The effects include induction of: 1) pro-resolution processes due to induction of leukocyte apoptosis, 2) direct immunomodulating effects (inhibition of pro-inflammatory Nuclear Factor kappa B and CXCL8, as well as Leukotriene B₄), and 3) the synthesis of Lipoxin A₄, a lipid mediator with potent pro-resolution properties. The findings may help lead to the targeted development of new antimicrobials with enhanced clinical benefits.

Comments: Bovine respiratory disease, such as that caused by Mannheimia haemolytica, is characterized by the exacerbated accumulation of neutrophils and pro-inflammatory mediators such as interleukin-8 (CXCL8) and Leukotriene B₄. This results in the severe inflammation ultimately responsible for pulmonary failure and death. Neutrophil cell death by apoptosis, rather than necrosis, helps resolve inflammation. Phagocytic clearance of apoptotic neutrophils by macrophages, known as efferocytosis, plays a key role in the resolution of inflammation. Hence, accumulation of neutrophils, leukotriene B₄, and CXCL8 are markers of inflammation-induced pathology, while lipoxin A₄ synthesis and neutrophil apoptosis mediate the resolution of inflammation. We postulated that the efficacy of tulathromycin in the treatment of bovine pneumonia could not be explained solely on the basis of its anti-microbial activity. The development of novel, clinically more effective anti-microbials is sorely needed. The discovery that an antimicrobial with superior clinical efficacy may confer strong and direct anti-inflammatory benefits by combining induction neutrophil apoptosis and inhibition of the local synthesis of pro-inflammatory cytokines and lipid mediators, while inducing the release of pro-resolution mediators, paves the way towards novel approaches in drug design.

Therapeutics & Pharmacology

P04-004-127

Efficacy of pegbovigrastim for reducing the incidence of naturally occurring clinical mastitis in periparturient dairy cows and heifers

Peter Canning¹; Renee Hassfurther²

¹Bioproduct Innovation R&D, ²Dairy Development R&D, Elanco Animal Health, Greenfield, United States

Objectives: Periparturient dairy cows and heifers are known to experience impaired neutrophil function leading to increased susceptibility to intramammary infections during early lactation. Bovine granulocyte colony stimulating factor (bG-CSF) has been shown to improve neutrophil function in periparturient cows. The objective of this study was to evaluate the effects of various dose levels of pegbovigrastim (PEGylated bG-CSF) upon the incidence of naturally occurring clinical mastitis in periparturient dairy cattle.

Materials and Methods: A total of 211 periparturient Hostein-Friesian cows and heifers were used for this study. Approximately seven days before their anticipated calving date, healthy animals were treated with either sterile saline or 5, 10 or 20 ug/kg of pegbovigrastim by subcutaneous injection. Animals were commingled and housed in a pen with dirt flooring which was kept wet to maximize exposure to bacterial pathogens and the incidence of naturally occurring clinical

mastitis. Within 24 hours of calving, each animal was dosed again with their assigned treatment. Absolute neutrophil counts (ANC) were determined for each animal prior to treatment, 24 hours after the first dose and on Day 7 post-calving. The condition of their mammary glands and milk were visually scored at each milking for 28 days after calving for abnormalities. Milk samples were aseptically collected from quarters exhibiting either an abnormal appearance or abnormal milk to identify pathogens. Daily milk production was recorded and milk composition was also assessed on Days 3, 5, 7 and 10 post-calving.

Results: All three doses of pegbovigrastim induced a statistically significant ($p < 0.01$) increase in ANC within 24 hours after dosing. Animals treated with either 20 or 10 ug/kg of pegbovigrastim exhibited ANC that were significantly ($p < 0.01$) increased relative to the saline controls on Day 7. Animals treated with 20 or 10 ug/kg of pegbovigrastim exhibited statistically significant ($p < 0.05$) reductions (72 or 50%, respectively) in the incidence of clinical mastitis relative to the saline controls. Animals treated with 5 ug/kg of pegbovigrastim exhibited a numerical reduction in the incidence of clinical mastitis which was not statistically significant ($p > 0.05$). The primary bacteria associated with these infections were environmental streptococci, coagulase negative staphylococci and coliforms. Administration of pegbovigrastim had no significant impact upon daily milk production or milk composition.

Conclusions: These results suggest pegbovigrastim is effective for reducing the incidence of naturally occurring clinical mastitis in periparturient dairy cows and heifers and warrants further investigation as a potential preventative intervention.

Pharmacokinetics of Ampicillin-Sulbactam in Serum and Synovial Fluid Following Regional Intravenous Administration in the Distal Hind Limb of Cattle

Sarah M. Depenbrock¹; Katharine M. Simpson¹; Andrew J. Niehaus¹; Jeffrey Lakritz¹; Mark G. Papich²

¹Department of Veterinary Clinical Sciences, The Ohio State University, Columbus, ²Department of Biomedical Sciences, North Carolina State University, Raleigh, United States

Objectives: To document the concentration versus time curve of ampicillin and sulbactam in synovial fluid (SYN) and serum of the digital circulation and central venous circulation following administration as a regional intravenous perfusion (RIVP) in the distal hind limb in cattle.

Materials and Methods: A prospective observational pharmacokinetic study was performed using six systemically healthy, non-pregnant, non-lactating adult Jersey or Jersey-cross cows. An RIVP was performed using a tourniquet applied to the right proximal metatarsus and 1.5 g combined ampicillin-sulbactam (1 g ampicillin, 0.5 g sulbactam) was administered in the right hind dorsal common digital vein (DCDV).

Indwelling catheters were used to collect serum (right hind DCDV and jugular vein) and synovial fluid (SYN; right metatarsophalangeal joint) at 0, 0.25, 0.5, 0.75, 1, 1.5, 2, 4, 6, 8, 12, 18, and 24 h post infusion. Furthermore, a single serum sample was collected from the abaxial proper plantar vein of the lateral digit of the right hind limb at 0.25 h post infusion. Serum and SYN were analyzed with high-performance liquid phase chromatography.

Results: Maximum mean concentrations of ampicillin in SYN, DCDV, abaxial proper plantar and jugular venous serum was 1995 (± 1011), 4827

(\pm 1883), 5423 (\pm 1953) and 2.5 (\pm 1.6) $\mu\text{g}/\text{mL}$ respectively. Sulbactam concentrations followed similar trends to ampicillin, and remained near or above the manufacturer's formulation of 2:1 ampicillin:sulbactam ratio. The concentration of ampicillin in SYN remained above the Clinical Laboratory Standards Institute breakpoints of 8 and 0.5 $\mu\text{g}/\text{mL}$ for 18.9 (range 15.4-24.9) h and 30.6 (range 23.4-38.4) h respectively. No adverse events were encountered.

Conclusions: Administration of 1.5 g combined ampicillin-sulbactam as an RIVP in the distal hind limb of cattle provided high concentrations of both compounds in

SYN for the majority of a 24 h interval, whereas systemic concentrations remained low. Therefore, the use of this drug combination as an RIVP may be clinically useful for treatment of distal limb infections in cattle.

Determination and identification of toxigenic fungi and their producing mycotoxins in cattle feed from subsistence and commercial farms in South

Mulunda Mwanza^{1,*}¹Animal Health, North West University, Mmabatho, South Africa

Objectives: Exposure of animals to mycotoxins at high doses over a short period or low doses over an extended period, may affect their production, reproduction or growth. In addition, contaminated animal products (milk, meat and eggs) can possibly end up being consumed by both rural and urban populations and thus cause health effects with time, if exposure is prolonged. In this study, animal feed samples obtained from subsistence (SFs) and commercial farms (CFs) in selected areas of South Africa were analysed for fungal and mycotoxin contamination.

Materials and Methods: Feed samples (143) were obtained from rural subsistence farms (RSFs) (68) (mostly cereal remnants such as maize and brewer's meal) and CFs (75) (silage, cotton seed cake, brewer meal, maize meal, concentrates, compound feeds) in Limpopo, Mpumalanga, KwaZulu Natal, Gauteng provinces in South Africa. Feed samples were cultured for fungal isolation and DNA extraction done for PCR. In addition, extraction was done for mycotoxins using ELISA. The identification was done using Immunoaffinity column for HPLC and TLC.

Results: The results obtained showed that feed samples from both sources were contaminated with some of the major toxigenic fungal species; in the case of RSFs (% incidence): *Aspergillus flavus* (87%) *A. parasiticus* (43%) *A. niger* (69%) *A. ochraceus* (42%) *A. candidus* (23%) *F. verticillioides* (98%); *F. graminearum* (67%) and *P. verrucosum* (48.9%) and in CF samples: *A. flavus* (98%) *A. parasiticus* (51%) *A. ochraceus* (65%) *A. niger* (31%) *A. candidus* (21%) *F. verticillioides* (68%) *F. graminearum* (43%) and *P. verrucosum* (7%). Results of mycotoxin contamination showed the incidence of fumonisins (FBs) in RSF and CF samples of 90.6% and 93.3%, respectively with mean values of 1136.5ppb and 1045.5ppb; and aflatoxin (AF) contamination was 92.0% in RSF samples and 96.2% in CF samples with mean concentrations of 168.8ppb and 294.1ppb, respectively. The incidence rate of ochratoxin A (OTA) in RSF and CF samples were 85.4% and 83.7% with mean concentrations of 67.6ppb and 89.4ppb, respectively with zearalenone (ZEA) mean concentrations of 43.5ppb and 62.7ppb having an incidence of 50.6% and 55.3%, respectively. In addition, a co-occurrence of fungi and mycotoxins was found in both RSF and CF samples with 50.5% of RSF and 53% of CF samples being contaminated with all four analysed mycotoxins, whereas, 81.2 % and 79.5% of samples were contaminated with FBs, AFs and OTA mycotoxins simultaneously.

Conclusions: Although this study shows that both RSF and CF feed contained toxigenic fungal spp. and mycotoxins at similar frequencies and levels, all concentrations obtained for mycotoxins were above acceptable limits and thus of impact on animal health risk for human consumers. In addition, the co-occurrence of fungal strains in same samples and mycotoxins in animal feed raised the issue of additive and synergistic effects on animals.

Toxicology

P04-004-200

An unusual case of Paraquat poisoning in two calves

William Fitzgerald^{1,*} John Moriarty² Maire McElroy² Edward Malone³ Maresa Sheehan¹ Micheal Casey⁴

¹Kilkenny Regional Veterinary Laboratory, DAFM, RVL Kilkenny, Kilkenny, ²Veterinary Pathology Department, Central Veterinary Research Laboratory, DAFM, ³Veterinary Toxicology Section, State Laboratory, ⁴Head of Regional Veterinary Laboratories, Central Veterinary Research Laboratory, DAFM, Backweston, Co Kildare, Ireland

Objectives: Paraquat, a bipyridyl herbicide, is widely sold for the control of broadleaved weeds. Toxicity in animals usually occurs after oral exposure. Paraquat is selectively toxic to lung where it accumulates in type I and II pneumocytes. The superoxide produced causes lipid peroxidation and necrosis. In animals that survive the acute phase, attempted repair results in progressive pulmonary fibrosis. Large doses may cause alveolar oedema, kidney and liver toxicity. There are numerous reports of paraquat toxicity in humans, dogs, cats and pigs but few in farmed animals. This report describes paraquat poisoning in two 10-week-old calves.

Materials and Methods: Two 10-week-old animals from a batch of 10 that were suffering from longstanding ill-thrift but presented acutely as recumbent and moribund were referred to Kilkenny Regional Veterinary Laboratory. The herdowner had raised concern about deliberate poisoning of the animals by a third party.

Full necropsy was performed. Sections of lung, liver, kidney and brain were processed by haematoxylin and eosin for microscopic examination. Lung, liver and faeces were cultured on xylose lysine deoxycholate (XLD) and ovine blood agar at 37°C. Liver and kidney were tested by atomic absorption spectrophotometry for copper and cobalt, lead and selenium respectively. Lung was tested for BHV-1, BRSV, PI3, BVD and BoCo viruses by real-time polymerase chain reaction (rt-PCR).

Liver and kidney samples from these calves, as well as samples of, water and feed to which these animals had access were tested by liquid chromatography & mass spectrometry (LCMS) at the State Laboratory, Backweston.

Results: Grossly the lungs were oedematous and congested. Grain was found in the ruminal contents, in one calf, approximately 5% of the grain was stained blue-green in colour. No other significant gross findings were present. Histopathological changes were most pronounced in the sections of liver and indicative of a severe acute to subacute, toxic hepatopathy in both animals (diffuse feathery degeneration, lipidosis, severe apoptosis in zones 1 and 2, mild biliary hyperplasia) and toxic nephropathy in one animal (diffuse lipidosis of renal tubular epithelium). Pulmonary changes were non-specific and primarily inflammatory in nature.

Paraquat was identified at apparently high concentrations in tissues from these two animals. Concentrations of the order of 12.9ug/g and 22ug/g in liver and 76ug/g and 166ug/g in kidney in the respective animals were determined. Chemical testing of water and feed, to which animals had access, were quantified at concentrations of the order of 2700ug/ml and 233ug/g respectively.

Findings from all other test results were insignificant and not considered a contributory factor in death of these animals.

All ten calves in the batch were reported by the referring veterinary practitioner to have died over the course of nine days, and none entered the food chain.

Conclusions: A diagnosis of paraquat poisoning was made based on demonstration of internal exposure, presence of a toxic hepatopathy and estimation of dose. A lethal dose of paraquat for cattle is considered to be 50mg/kg BW herbicide *per os*. In this case the dose rate based on consumption of contaminated water was estimated at between 288 and 315mg/kg BW.

Paraquat toxicity is biphasic, initially causing hepatic and renal insufficiency and pulmonary oedema followed by pulmonary fibrosis. The lack of pronounced lung pathology such as fibrosis normally associated with paraquat poisoning, may be due to the acute nature of death post exposure in this case.

P04-004-201

Monitoring Natural Feed Contamination Of Mycotoxins In Cattle: Metabolite Profiling Using Gas Chromatography-Mass Spectrometry

Mitsuhiro Takagi¹, Seiichi Uno², Emiko Kokushi², Missaka P. Wijayagunawardane³, Johanna Fink-Gremmels⁴

¹Yamaguchi University, Yamaguchi City, ²Kagoshima University, Kagoshima, Japan, ³University of Peradeniya, Peradeniya, Sri Lanka, ⁴Utrecht University, Utrecht, Netherlands

Objectives: We previously reported a cattle herd that had an extensive contamination of feed with multiple mycotoxins such as zearalenone (ZEN) and sterigmatocystin (STC), and proposed to create a database for assessing potential risk factors for cattle health (Takagi et al., 2014 in WBC). Mass-spectrometry combined with gas chromatography (GC/MS) is a potentially useful tool for metabolomics, because of its high sensitivity, peak resolution and reproducibility. The objective of the present study was to evaluate the metabolic profiling of the cattle fed with or without ZEN/STC contaminated diets using GC/MS metabolomics approach.

Materials and Methods: Urinary samples were collected from individual animals (n=6 per herd) of fattening Japanese Black (JB) cattle herds. Herd 1: known to have persistently high urinary ZEN/STC concentrations due to the contaminated rice straws (ZEA; 7.5 mg/kg, STC; 0.24 mg/kg). Herd 2: a second fattening herd, which had a same feeding pattern as Herd 1, except for the rice straw (ZEA; LOD, STC; < 0.01 mg/kg). Herd 3: JB breeding cattle herd, with a different composition meeting the requirement of a breeding herd (ZEA; average 0.06 mg/kg, STC; not test). Additionally, urine samples were collected from Herd 1 two weeks after replacing the newly un-contaminated rice straw in feed (denoted Herd 1N: ZEA; LOD, STC; 0.04 mg/kg). Metabolites were extracted from the urine, derivatized and analyzed by GC/MS. Identified metabolites were subjected to ANOVA and principal component analysis (PCA). The variations in the amounts of the metabolites of each group were compared.

Results: Four groups were separated along PC1, confirming that the effects of ZEN/STC depend on exposure levels. The PCA results indicate that the metabolic profiles variation in each group differs. Typical variations were the amounts of glycine conjugates, which tended to be higher in Herds 1 and 1N than in Herds 2 and 3. This finding suggests an increased hepatic activity associated with detoxification. Similarly, the amounts of metabolites associated with gluconeogenesis and taurine metabolism tended to be higher in Herds 1 and 1N than that of Herds 2 and 3, which may suggest increased energy utilization in response to the stress condition in liver induced by the contaminants. The concentration

of hippurate that is clearly higher in Herd 3 than herds 1, 1N and 2 may be due to different dietary roughage content.

Conclusions: Our results indicate that the contamination of cattle feed with multiple mycotoxins such as ZEN and STC may result in an altered glycine metabolism and gluconeogenesis when compared with non-contaminated cattle. This first approach also suggests that monitoring endogenous metabolites in urine samples (metabolomics) is a useful tool to evaluate the effects of exposure of cattle to multiple mycotoxins. Further field studies should be carried out to create a database for the assessment of multiple mycotoxins as risk factors for cattle health and productivity.

Hepatic lesions compatible with Pithomycotoxicosis (Facial Eczema) in cattle of São Miguel and Terceira Islands – Azores, Portugal

Clara Dias¹, Helder Cortes², Carlos Pinto³

¹University of Évora, ²Victor Caeiro Laboratory of Parasitology, Instituto de Ciências Agrárias e Ambientais Mediterrânicas (ICAAM), University of Évora, Núcleo da Mitra, P.O. Box 94, 7006-554, Évora, ³Serviço de Desenvolvimento Agrário de São Miguel, Quinta de São Gonçalo, 9500-343, Ponta Delgada, Portugal

Objectives: Pithomycotoxicosis is an intoxication caused by sporidesmin (SPD), a mycotoxin produced by fungus *Pithomyces chartarum*. Animals like sheep or cattle are more likely to develop hepatobiliary lesions when intoxicated. This disease was first located in New Zealand during the last half of 19th Century. In Azores, in the beginning of the millennium, SPD was identified as one of the causes of photosensitivity. The goal of this study was the establishment of the prevalence of calved cows with hepatic lesions compatible with Pithomycotoxicosis (HLCP), the age of animals, the degree of lesions and their impact on carcass evaluation.

Materials and Methods: Liver inspection was done during meat inspection on slaughterhouse line [abattoir from São Miguel Island (SMI) and Terceira Island (TI)] where liver was evaluated by observation and palpation. Livers with HLCP were categorized in four grades of severity [I (GI)-mild, II (GII)-moderate, III (GIII)-intense, IV (GIV)-severe]. Hepatic samples of each group were collected, fixed in 10% buffered formalin and submitted to routine histopathological analyses for microscopic confirmation of probable diagnosis. Collected data were used to determine the hepatic rejection rate (HRR), approbation rate (AR) and rejection rate (RR) of carcasses.

Results: In SMI were observed 1,331 livers. The average age (AA) of cattle was 80.34±29.847 months (m) and average weight (AW) was 261.34±49.491Kg. 23.37% of 1,331 livers had HLCP and this sample group showed AA of 86.49±29.817m and AW of 255.76±48.263Kg. 8.64% of the sample with HLCP exhibited GI lesions, 7.21% GII, 5.71% GIII and 1.80% GIV, with AA of 79.83±26.306m, 89.04±30.311m, 93.24±32.362m, 86.83±30.721m and AW of 262.89±49.160Kg, 257.93±50.147Kg, 248.80±45.734Kg, 234.92±36.377Kg, respectively. The AR of carcasses from total sample was 77.46% and the RR was 8.79%. The HRR of total sample was 97.75%, being the main causes of rejection telangiectasy (26.44%), fibrosis/sclerosis (F/S) (24.75%). In TI were observed 410 livers. The AA of cattle was 81.28±32.551m and AW was 259.09±42.418Kg. 29.51% of 410 livers had HLCP and this sample group showed AA of 93.16±29.741m and AW of 256.86±42.331Kg. 13.66% of the sample with HLCP exhibited GI lesions, 10.24% GII,

4.63% GIII and 0.98% GIV, with AA of 90.70±31.159m, 95.67±28.237m, 96.11±31.186m, 87.25±23.372m and AW of 260.54±40.477Kg, 261.91±46.386Kg, 241.47±37.828Kg, 225.25±14.338Kg, respectively. The AR of carcasses from total sample was 89.02% and the RR was 3.66%. The HRR of total sample was 69.02%, being the main causes of rejection the telangiectasy (24.03%), the F/S (23.32%). Meat Inspector (MI) can indicate only one hepatic rejection cause however livers can show more than one signal of pathology, what can only justify 65.1% (SMI) and 38.2% (TI) of the rejected livers with HLCP were, effectively, rejected because of F/S by MI.

Conclusions: The prevalence of cows with HLCP represents almost 1/4 to 1/3 of the sample. Worst lesions appear on older cows (SMI R=0.154; TI R=0.288), except in cows with GIV lesions. Maybe cows with worst HLCP have reduced life time. With increasing HLCP grade carcass weight decreases (SMI R=-0.089). Lighter cows are more prone to SPD action presenting worst lesions or cows intoxicated with SPD have less metabolic ability, resulting in lighter carcasses. Pithomycotoxicosis may be underestimate since there are livers with HLCP not rejected by F/S, this happens mainly in livers with lower grades of HLCP and signals of diverse diseases.

Toxicology

P04-004-203

CASE REPORT: Monensin Intoxication in Bubalus bubalis Calves

Daniel Zeledon-Donzo ¹Humberto Cedeño ²Carlos Luna-Tortós ³Alejandro Alfaro-Alarcon ⁴

¹Private Practice, Veterinaria Guatuso, San Rafael de Guatuso, ²Catedra Clinica Especies Mayores, ³Catedra de Farmacologia y Toxicologia, ⁴Laboratorio de Patologia, Escuela de Medicina Veterinaria, Universidad Nacional, Heredia, Costa Rica

Objectives:

1. To define the cause of massive sudden death of calves in a Bubalus bubalis exploitation in the Northern Pacific region of Costa Rica.
2. To establish a therapeutic management to recover the affected animals.
3. To recommend a proper management to control future loses.

Materials and Methods: The assessment included a complete evaluation of the history and records, physical examination, field inspection, toxicological evaluation of pastures to assess the content of Cyanide and Nitrates, analysis of the levels of methahemoglobin, Complete Blood Counts, Total Protein levels measurement, Creatine phosphokinase levels measurement, electrocardiographic examination, ecocardiographic examination, necropsies and histopathology. Animals with and without clinical signs compatible with the traditional presentation of the deaths were evaluated.

Results: It was found that the animals affected were only the recently weaned. All animals were eating in similar pastures. The weaning calves were administered a cattle calf concentrate with 60 mg/kg of monensin. Other animals were given a lactating cow concentrate with 30 mg/kg of monensin. The weaning group had a bad body condition score, hirsutism, weakness and anemia. The affected animals that had not died were tachypneic, open mouth breathing and with foam in the mouth. High levels of cyanide and nitrates were found in the pastures. Although the clinical signs were compatible with these intoxications, the specific treatment did not show a consistent response. The animals kept

dying even when they were moved to other pastures with lower levels of cyanide and nitrates. The electrocardiographic findings showed an increase in the height and length of the P wave of the affected animals. The ecocardiographic findings showed a decrease in the width of the cardiac walls of the affected animals. Three necropsies were performed. The findings showed paleness of the miocardic muscle and skeletal muscles. A necrotizing lymphohystiocitic miostis from low to moderate was found in the heart and skeletal muscle. A semitendinosus and semimembranosus biopsy was taken in an affected lying animal. The hystopathology revealed a severe necrotizing lymphohystiocitic miostis. The levels of CPK in this animal were elevated. The substitution of the concentrate with other with no monensin stopped completely the mortality in the weaning group of the farm.

Conclusions: It was concluded that the monensin in an estimated range from 0.6 – 0.8 mg/kg could be toxic in Bubalus bubalis. The monensin in Bubalus bubalis behaves as a myotoxic agent. Nevertheless there were evidence of a presence of cyanide and nitrate in the pastures, it was not the primary agent affecting the animals.

Tuberculosis

P01-001-166

1. Advances in monitoring of tuberculin testing in the Irish bTb eradication programme 2008 - 2014

Anthony Duignan¹, S. J. More² and Bovine Tuberculosis

¹Department of Agriculture Food and Marine, Department of Agriculture Food and Marine, ²UCD Centre for Veterinary Epidemiology and Risk Analysis, University College, Dublin, Dublin, Ireland

Objectives: This study sets to evaluate the impact of enhanced quality controls on key performance indicators of Single Intradermal Comparative Cervical Tuberculin Test (SICCT) performance during the period 2008 to 2014 using analysis of data captured in specialist reports on testing details of individual PVPs. These data facilitate monitor of individual and collective delivery of the SICCT by Private Veterinary Practitioners (PVPs).

Materials and Methods: A specialist report using the Department of Agriculture Animal Health Computer System (AHCS) was introduced in 2008 to monitor the performance of each PVP in delivery of the national bovine tuberculosis (bTb) eradication programme. The report captures all data relevant to each PVP and concentrates on Key Performance Indicators (KPI) that affect the quality of both administrative and field performance. The KPIs enable comparison of PVP performance over time and between peers. The key measures of performance are critical control points which were chosen because they are objective and readily measurable. Since the introduction of the reports in 2008 there have been considerable changes in on individual tester performance both in relation to programme delivery and disease detection performance. The data recorded all tests conducted by PVPs on cattle in Ireland from January 2008 to December 2014 including dates, circa 116,000 herds and test readings for circa 8.5 million animal tests per annum. Statistical analysis was performed on numbers of herds tested, animals tested, clear animals reactors identified as reactors within six months at a subsequent test, abattoir cases detected in clear animals within six months of test, amendments to details of tests previously certified, late test report submissions and non-compliance with advance itinerary requirements. All tests were included regardless of geographic location, herd size or local area prevalence of bTb.

Results: These data indicate that the total number of PVP engaged in testing has not changed considerably from 947 in 2008 to 970 in 2014. The mean number of animal tests has decreased from 8,696 in 2008 to 8,224 in 2014 mainly due to a decrease in disease incidence and reduction in consequential testing of infected and contiguous herds. The mean number clear animals tested by each PVP which were identified as reactors within six months at a subsequent test declined from 2.09 in 2008 to 1.22 in 2014. The mean number of confirmed abattoir cases detected within six months in animals tested clear fell from 2.11 in 2008 to 1.03 in 2014. Submissions of subsequent amendments to test details for tests previously certified reduced from a mean of 3.1 in 2008 to 1.1 in 2014. Late test report submissions reduced from a mean of 16.3 in 2008 to 3.2 in 2014. Non-compliances with advanced itinerary requirements reduced from a mean of 25.5 in 2008 to 6.7 in 2014

Conclusions: The decline in back trace detection test positive and disclosure of TB lesions at slaughter of recently tested clear animals indicate improvement in disease detection. The frequency of amendments to certification (AHCS 1 submissions), conformity with advanced itinerary submission and punctuality of test report submissions are independent of disease prevalence and therefore reflect change in behaviour by PVPs. The data indicate an improvement in the quality of testing by PVPs since the introduction of the specialist reports in 2008 and is likely to be a factor in the concurrent reduction in disease prevalence.

Improved robustness of bovine Tb testing using a second generation Interferon Gamma Release Assay based on peptide antigens and In-tube technology

Claudia Engemann¹

¹QIAGEN Leipzig, Leipzig, Germany

Objectives: For human Tb-diagnostics, Interferon-gamma release assays (IGRA) based on modern peptide antigens like QIAGEN's QuantiFERON-TB Gold In-Tube (QFT-IT) has become the test of choice in screening for TB infections. But in veterinary diagnostics, in particular for bovine TB testing, IGRAs are not yet widely accepted. The study presents data on improved robustness and convenience of bovine Tb testing using a modern peptide-based In-tube IGRA technology.

Materials and Methods: While IGRAs become more and more the Golden standard for diagnosis of Tb in humans, this method is not yet well accepted in diagnostics of bovine Tb yet. There are concerns about the accuracy of test results obtained with available first-generation PPD-based IGRAs. A specificity range of 87.7 to 99.2% was reported, which causes problems in low prevalence areas.

New peptide antigens were successfully validated in bovine Tb research studies but were not yet available in easy to use diagnostic kit format. These peptide antigens show higher specificity without marked loss of sensitivity, no cross-reactivity in paratuberculosis-infected herds and potential to differentiate vaccination using BCG vaccines from bovine TB infection.

QFT-IT is an advanced blood test and represents a new generation of peptide-based IGRAs that are more accurate, faster, and cost-effective than older tests and other methods. The assay measures the cell-mediated immune response of TB-infected individuals.

QFT-IT uses special sample collection tubes with peptide antigens that are coated directly on the tube walls. Those vacuum tubes allow the collection of 1ml of blood sample during the bleeding process. Incubation of samples in these tubes eliminates the need for expensive shipping samples at 37°C in a narrow time window. After a stimulation step for 24h at 37°C plasma from the TB antigen tube and Nil tube is tested with the cattletype® IFN-gamma ELISA.

Plasma samples can be tested manually or automated using the DS2® ELISA Processing System or the DSX® ELISA Processing System (available from QIAGEN).

Results: In order to improve the logistic pathways for samples, a robustness study was performed for the QFT In-tube method. 1 ml aliquots of blood samples from skin test positive animals were transferred to 3 QFT TB tubes and 1 Nil tube. One Tube was held at 4°C for 24 h and another tube was held at 20°C for 24 h prior to the 37°C stimulation incubation. Results obtained with the previously stored tubes were compared to the results obtained with the standard procedure.

The sample storage at 4°C showed no ponderable impact on the test results (average S/P values +2.4%). When stored at 20°C for 24 h S/P signals decreased on average 24.6%, but no false negative results were observed compared to the standard method.

Conclusions: A new generation of IGRA using modern antigens in a user-friendly In-tube format as described here has the potential to overcome the obstacles of lack of robustness and specificity and for a new quality of Tb testing in veterinary diagnostics.

The bovine tuberculosis risk conferred by the purchasing herd post movement.Elizabeth A. Lane¹; Margaret M. Good²¹Department of Agriculture, Food and the Marine, Backweston Campus, Celbridge, County Kildare, ²Department of Agriculture, Food and the Marine, Kildare Street, Dublin 2, Ireland

Objectives: Bovine tuberculosis (bTB) is subject to a compulsory eradication programme in Ireland. The programme operates under national legislation and fulfils the requirements of the relevant European Union Trade Directives. Movement restrictions form a key component of the programme. In excess of 2.8 million farm to farm bovine movements are recorded annually. The aim of this study was to estimate the risk of a positive bovine tuberculosis (bTB) skin test conferred by the purchasing herd post movement.

Materials and Methods: Data were gathered from the Animal Information and Movement System (AIMS) database corresponding to cattle movements (n = 402,365) into herds that subsequently had a bTB breakdown between 2011 and 2013. A backwards stepwise multivariable logistic regression model was developed to evaluate the independent factors; year, animal age, sex, movement to test positive interval, and purchasing herd factors including herd size, location, management, and test-type, accounting for herd structure, on the risk of becoming positive to the bTB skin test.

Results: Only 0.44 % of animals moved into herds that subsequently breakdown with bTB are skin test positive within two months. While, 0.95 % of animals that moved herds within the past year subsequently test positive to the bTB skin test. The odds ratio for a positive bTB skin test increased (P < 0.001) in animals tested more than two months after a move. Animals were 1.32 times (confidence interval; CI 1.13 to 1.54) more likely (P < 0.001) to be bTB skin positive if tested more than two months post move compared with those tested within two months of a move (referent level). The risk of disclosing a bTB positive animal was greater (P < 0.001) the smaller the purchasing herd. The location of the purchasing herd altered the bTB reactor risk, with purchased animals in herds located in areas with high infection pressure two times (CI 1.64 to 2.42) more likely (P = 0.004) to be positive to the bTB skin test compared with animals in herds located in low risk areas. The management choice to purchase through a public market lowered (P = 0.004) risk compared with purchase direct from farm.

Conclusions: Although it is widely accepted that the seller herd influences the bTB risk, these data provide evidence that purchasing herd size, location and method of purchase alters bTB risk. In conclusion, the purchasing herd confers a substantial risk of an animal becoming bTB positive following movement.

Tuberculosis

P01-001-170

Monitoring the effectiveness of Irish factories in the surveillance of slaughtered cattle for tuberculosis lesions: An update for years 2008-2010Francisco Olea-Popelka¹; Laura Martin¹; Paul White²; James O'Keefe²¹Clinical Sciences, College of Veterinary Medicine and Biomedical Sciences, Colorado State University, Fort Collins, United States,²Department of Agriculture, Food and the Marine, Dublin, Ireland

Objectives: In Ireland, every animal is examined at slaughter for its fitness for human consumption. The detection of tuberculous lesions at slaughter has proved to be an essential component of the bovine tuberculosis (TB) surveillance system for the cattle population. The aim of this study has been to monitor and determine the relative effectiveness of factories in submitting and subsequently in having suspect lesions confirmed as bovine tuberculosis (TB) lesions from cattle from attested herds (i.e. herds classified free of bovine TB). Thus, this study provides an update for the period 2008-2010 that serves as comparison to previous years (2005-2007).

Materials and Methods: Data were obtained from the Department of Agriculture Food and the Marine (DAFM), Ireland. Factory data regarding number of animals slaughtered, numbers of bovine TB lesions submission and laboratory confirmation results were evaluated for all export-licensed factories in Ireland. Additionally, animal movement and TB tuberculin test results were obtained. A Multivariable logistic regression model was developed to calculate the risk of lesion submission (and separately confirmation risk) for each factory, using animal as the unit of analysis. The model included the following potential confounding factors: the sex, age and origin of each animal, the slaughter season, and, for each animal's herd of origin, the length of the TB clear period for the animal source herd and the District Electoral Division (DED) bovine TB risk. The adjusted and crude lesion submission (and separately confirmation) risks were compared to determine the effect of this adjustment on the estimates of risk on the ranking of the factories.

Results: Our results show that for the period 2005-2007, the observed (crude) factory submission risk ranged from 0 to 52 per 10,000 animals slaughtered. There was a five-fold range in lesion submission risk among Irish factories. The average crude submission risk (25 per 10,000) during 2005-07 was higher than found in previous years (21.8 per 10,000; 22 per 10,000). For the period 2005-2007, the variation in crude submission risk among factories 5-fold was lower than reported previously, which was lower than the 7-fold difference and a 9-fold difference found in previous studies before 2005. For the period 2005-2007 the factory confirmation risk ranged from 30.2% to 90.1%, with an average of 68.5%, and this average was slightly higher than the 64.4% reported for years before 2005. The data for the period 2008-2010 will be analyzed and presented in July 2016.

Conclusions: Our studies over the years have shown substantial variation in the effectiveness of lesion submission and subsequent confirmation as bovine TB among Irish factories. Our updated analysis for the years 2008-2010 will provide important information to managers to assess progress towards reducing the variability in submission and confirmation risk for bovine TB. Thus, this study is important as part of quality control in the national bovine TB programme.

P01-001-171

Assessment of an advanced interferon- γ assay under field conditions of Piedmont region (Italy)Alessia Di Blasio¹; Mara Perosino¹; Angela Pontei¹; Giovanna Petruccielli¹; Simona Zoppi¹; Alessandro Dondo¹¹Istituto Zooprofilattico Sperimentale del Piemonte, Liguria e Valle d'Aosta, Torino, Italy

Objectives: BOVIGAM® is a ELISA kit certified by the OIE to control bovine tuberculosis in cattle, showing good sensitivity and specificity. Piedmont region is obtaining officially bTB free status after 14 years of a strategic application of g-interferon assay (g-IFN) as ancillary test of Skin Intradermal Test (SIT), that shows under field conditions high specificity but lower sensitivity respect to γ -IFN. In order to improve diagnostic performance, optimizing local bTB eradication program, an advanced g-IFN (BOVIGAM® 2G) was evaluated under field trial conditions.

Materials and Methods:

Herds were selected:

- bTB free herds with SIT negative results in order to evaluate specificity;
- bTB infected herds with SIT and/or interferon- γ assay positive results and *M. bovis* culture and/or PCR positive in order to evaluate sensitivity.

All collected animals resulted:

- not vaccinated with BCG vaccine;
- older than 6 month;
- without respiratory diseases at the moment of sampling.

The specificity of BOVIGAM® 2G was calculated collecting and analyzing 176 blood samples from 8 different bTB free herds. For each samples was performed simultaneously BOVIGAM® and BOVIGAM® 2G ELISA. In order to assess sensitivity, 109 animals have been collected from 15 different bTB infected herds. The whole blood stimulation was performed with Avian and Bovine Italian PPDs (Purified Protein Derivative), Avian and Bovine Lelystad PPDs, Peptide Cocktail E-C (Mix A) with high specificity and ideal for monitoring purposes, Peptide Cocktail H-P (Mix B) with high specificity and sensitivity useful during eradication programs and Pokeweed Mitogen. BOVIGAM® 2G ELISA was carried out in two different ways using either manufacturers' interpretative criteria than those described by Dondo et al. . Sensitivity, specificity and agreement for each test and criteria were evaluated using WinEpi© tool (Ignacio de Blas. Facultad de Veterinaria, Universidad de Zaragoza, 2006).

Results: 38 samples showing high Optical Density (O.D.) values for the nil antigen, reduced to 25 using an highest cut-off value, were removed from the study, due to an aspecific interferon γ production. For all samples, it needed also to reduce the conjugate incubation time in order to avoid overflow values and allow the correct OD values interpretation. This trial under field condition assessed BOVIGAM® 2G test has a sensitivity slightly more low than that obtained by BOVIGAM®, although not statistically significant. Otherwise, the specificity is good with values higher than 96% for all of antigens tested, except for MIX B (93.8%; IC: 90.1-97.3%). It was observed a good agreement in all of methods tested, obtaining KAPPA coefficient values ranging from 0.462 to 0.838; however the highest levels of agreement were between SIT and BOVIGAM® 2G.

Conclusions: bTB diagnosis is complex and requires in vita diagnostic tools flexible and form fitting to specific local situation. Our results indicate BOVIGAM® 2G improves specificity, that is useful during monitoring programs in bTB low prevalence region, such as Piedmont Region, where the study was conducted. More studies should be carried out in our region to better assess the use of both peptide cocktails (MIX A and MIX B) and define their strategic application in our bTB situation to optimize control actions.

Comments: The authors acknowledge Thermo Fischer Scientific for technical and scientific support including the supply of materials used in this trial.

Validation of stimulants and interferon gamma ELISA for bovine tuberculosis detection

Anna Greatrex^{1,*}Loïc Comtet²Laura Olagnon²Philippe Pourquier³

¹IDvet, 34790 Grabels, France, ²R&D, ³Director, IDvet, 34790 Grabels, France

Objectives: IGRA (Interferon Gamma Release Assay) is widely used to detect the cellular response to pathogens such as *Mycobacterium bovis* by measuring the difference between activated and non-activated whole blood interferon gamma (IFN γ) signals. IDvet offers a complete solution for the detection of bovine tuberculosis. It includes stimulation antigens and an ELISA kit for detection. The aim of this study is to assess the performance of this solution (sensitivity, specificity, repeatability, reproducibility, and stability).

Materials and Methods: PPDa and PPDb tuberculins (IDvet) were used as stimulation antigens. IFN γ level was then determined using the (ID Screen®) Ruminant Interferon Gamma ELISA (IDvet). All ELISA results were standardized and expressed as sample/positive control ratios (S/P). Different freeze-dried IFN γ reference materials were created from natural IFN γ from different species (bovine, ovine, caprine or buffalo). The stability, repeatability, reproducibility and robustness of the ELISA itself was studied. Specificity for bovine tuberculosis diagnosis was evaluated on cattle from different breeds and countries (n=1077). Sensitivity was evaluated in comparison with confirmatory techniques (PCR, single and comparative intradermal tuberculin test).

Results: The ELISA reagents showed high stability. Repeatability was excellent, with CV% values measured to be between 3 and 8%. Reproducibility was evaluated through the analysis of 60 dilutions of the freeze-dried bovine plasma standard by 4 French Departmental Laboratories in independent runs. S/P% values were between 55 and 68%, with a standard deviation (SD) of 3 and a coefficient of variation (CV %) of 5%: analytical sensitivity was found to be constant and equivalent between runs. Measured specificity was 99.0% (IC95 98.4 – 99.6%) and sensitivity was 88.3% (IC95 81.1 – 95.5%). Specificity was also high for Paratuberculosis-infected herds, even with high seroprevalence (Belgium: Sp= 98% and France, Midi-Pyrénées: Sp = 100%). Sensitivity with respect to confirmatory techniques was 88.3% (IC95 81.1 – 95.5%).

Conclusions: The use of the IDvet PPDs with the IDvet IFN γ ELISA gave a measured test sensitivity comparable to published values. The stability, repeatability and reproducibility of this ELISA was high. Thanks to the use of tuberculins with appropriate potencies, as well as well-defined interpretation criteria, test specificity was high. The performance of the IDvet PPDs and IFN γ ELISA meets bovine TB eradication program requirements.

A study of Irish Farmers, whose herds were depopulated as a result of Bovine Tuberculosis, in the years 2008-2010

James Casey^{1,*}

¹ERAD, DAFM, Dublin, Ireland

Objectives: This study documents Irish farmers' experiences of herd depopulations due to Bovine Tuberculosis. Depopulation is used as a programme measure when the infection level in a herd has surpassed 30%. Between 2008 & 2010, 87 farms had a full or partial depopulation of their herd. These herds accounted for 0.078% of herds nationally restricted in the three year period, but for 7% of all animals slaughtered as a result of bTB in the same period.

Materials and Methods: These farmers were surveyed, by means of postal questionnaire, telephone and face to face interview. The questionnaire was designed so as to extrapolate from results whether policy is fit for purpose. The response to the postal questionnaire was poor and telephone interviewing was far more effective in collecting information. Two cases of human infection were described in the survey and reminds why eradication is a national target.

This study conducted exploratory and descriptive research on the experiences of a specific group of Irish farmers to gain an understanding of the effects of herd depopulation due to bTB. The researcher used the data set of Irish Cattle Farmers who lost part or their entire herd in the years 2008, 2009 & 2010 and had two primary goals:

- Document their experience of depopulation
- Extrapolate from the documentation whether overall policy was fit for purpose for the eradication of bTB

Results: The results describe farmers' experience of depopulation and show that it is accepted by farmers as a necessary instrument of the national eradication campaign, especially once infection levels within the herd reach a critical level. Most farmers restocked with bovines and found the purchased herd to be healthier than the one it replaced. There was no one single reason for the breakdown, but some important themes emerged in terms of what was considered the cause and how to prevent a reoccurrence. Interpretation of their experience of the depopulation and their interactions with actors associated with service delivery makes a compelling case that the overall policy is working, albeit with variation and some areas of concern. The main themes of contention were compensation, stress in the home and workplace (sometimes associated with illness) and the feeling of being out of control and having a limited input into decision making. Some distinctions emerge in terms of family farms and farms that are run as businesses. The survey results are used to suggest pathways for re-engaging with the farming community with a view to expanding their role in disease eradication and to encourage proactive participation at a farm and industry level. A basic conceptual model was constructed to compare successful eradication campaigns with non-successful programmes.

Conclusions: The forces that influenced depopulation events were major infective outbreaks of bTB occasionally accompanied with non-specific infection. The causes of the outbreaks were split evenly between wildlife and bovine sources. The contentious areas of current bTB eradication policy are compensation, effective wildlife control, bought in infection, and poor tuberculin testing. The working hypotheses that are warranted based on farmer experiences to guide further research, include insurance, farmer removal of wildlife, accelerated capital allowances for disease prevention, prosecutions of negligence and stakeholder partnership.

In vitro Growth Inhibition of mastitis-causing bacteria by *Lactobacillus Plantarum* ATCC 8014

Maryam Bagheri Varzaneh ^{1*}

¹Department of Animal, Poultry and Aquatic Sciences, Agriculture Institute, Iranian Research Organization for Science and Technology (IROST), Tehran, Iran, Islamic Republic Of

Objectives: In recent years, global demand for organic dairy products has increased rapidly. There has been a huge growth in number of dairy farms being converted to organic management systems. Because of restricted use of antibiotics in an organic dairy farm, researchers' attention has been drawn toward probiotics and their by-products as natural remedies potentially replacing antibiotics. Since mastitis is a serious problem in dairy industry, the aim was to evaluate antibacterial potency of the cell-free lactobacillus supernatant against mastitis-causing pathogens.

Materials and Methods: Six mastitis-causing pathogens (*Staphylococcus aureus*, *S. non aureus*, *E. coli*, *Klebsiella* *Streptococcus agalactiae* and *Streptococcus dysgalactiae*) were isolated from bulk tank milk. *Lactobacillus plantarum* ATCC 8014 was cultured in De Mann Rogosa sharpe (MRS) broth for 24h at 37 °C in a candle jar. Cell-free supernatant (CFS) was obtained by centrifuging the culture medium at 3000 rpm for 15 minutes and was sterilized by a 0.45µm filter. Growth inhibition was determined in micro plates. Wells were filled with 80 µl Tryptic Soy Broth (TSB, as a culture medium), 100 µl CFS and 20 µl of each of pathogenic bacteria with a concentration of 10⁸ CFU/ml. Three and 18 wells, respectively were allocated to negative (100 µl TSB +100 µl CFS) and positive (PC, 180 µl TSB + 20 µl of each pathogen) controls. Sealed plate incubated at 37 °C for 24 h then OD₅₄₀ was measured by a microplate reader. Minimum inhibitory concentrations (MICs) and minimum bactericidal concentrations (MBCs) were determined by lyophilized CFS and microdilution method. Final volume of each well was 75 µl. Wells without CFS and with pathogen bacteria used as positive controls, while negative control wells contained only culture medium (TSB). Microplates were incubated at 37 °C for 24 h. A wire loop of wells without visible growth cultured on the nutrient agar plates for determination of MBC. Each run were repeated in triplicate and average of runs were analyzed by SAS.

Results: Pathogen inhibitory potency of CFS of *Lactobacillus Plantarum* ATCC 8014 was confirmed (P <0.001). There was no visible growth in treatments receiving CFS. The OD₅₄₀ of PC and CFS-containing wells were 1.062 and 0.027, respectively (for *S. aureus*), 0.886 and 0.039 (for *E. coli*), 0.689 and 0.068 (for *S. non aureus*), 0.769 and 0.06 (for *Klebsiella*), 0.518 and 0.028 for (*S. agalactiae*) and 0.522 and 0.06 (for *S. dysgalactiae*). MICs and MBCs were similar for all pathogens (8.45 mg/ml) except for *S. non aureus*. MIC and MBC for *S. non aureus* were 4.22 and 8.45 mg/ml, respectively.

Conclusions: Results obtained in this study suggest that *Lactobacillus plantarum* metabolites can inhibit growth of six common pathogens prevalent in dairy cow mastitis. However, chemical characteristics of these metabolites were not known in this experiment and should further be analyzed. Also, a complete understanding of the mode of action of these metabolites might have practical implication in natural cure of clinical mastitis cases.

Keywords: Inhibitory activity, *Lactobacillus*, Mastitis

Quantifying Milking Frequency Effects On Quarter Milk Production Rate

John Penry ^{1*} Peter Crump ² John Upton ³ Douglas Reinemann ⁴

¹Department of Dairy Science, ²College of Agriculture and Life Sciences, University of Wisconsin - Madison, Madison, United States, ³Animal and Grassland Research and Innovation Centre, Teagasc, Fermoy, Ireland, ⁴Biological Systems Engineering, University of Wisconsin- Madison, Madison, United States

Objectives: The objective of this observational study was to quantify the association between milking frequencies and quarter milk production rate (kg/hr) for primiparous and multiparous cows on a commercial dairy farm using a robotic automatic milking system technology.

Materials and Methods: Eight months of milk harvesting data was sourced from a 1400 cow commercial dairy farm using multiple, single stall robotic milking units. Individual quarter milk production rates were calculated for primiparous and multiparous cows during the days in milk windows: DIM 50-80, 100-130, 150-180. Milk production rate was calculated for all front and rear quarters by taking quarter milk yield and dividing this by the inter-milking interval (rounded to the nearest hour) for that specific cow and milking event. Hence, this calculation was performed for each individual milking. More than 250 individual milking observations had to be collated for any specific inter-milking interval for the data to be included and the analysis went up to a maximum interval of 14 hrs. Pre-milking preparation (teat cleaning and pre-stimulation) and detacher settings did not alter between milkings. Cows were assessed only against a time based threshold for gaining milking permission when they presented to a robotic milking unit. The minimum time since the last milking for any animal in the herd to be given milking permission was 4 hours. Descriptive statistics on milking frequency were also collated. Only analysis on left front and rear quarters is presented as results on left front and rear quarters compared with right front and rear were closely aligned.

Results: Rear quarters in this study population produced between 27.4 and 31.1% of total milk yield at an individual milking with front quarters producing between 19.0 and 23.2%. Hence, the milk production rate at the quarter level is, typically, higher for the rear compared to the front quarters. In this analysis, a significant trend of reducing milk production rate was evident for both primiparous and multiparous cows in all three DIM windows, for all quarters, from 4 hrs to 14 hrs inter-milking interval. Primiparous cows had a lower milk production rate when compared to multiparous cows by approximately 19%. Between inter-milking interval 4 and 12 hrs, multiparous cows had a maximum milk production rate (kg/hr) of 0.57 at 4 hrs (left rear, DIM 50-80) and a minimum rate of 0.30 at 12 hrs (right front, DIM 150-180). Primiparous cows had a maximum milk production rate of 0.43 at 4 hrs (left rear, DIM 50-80) and a minimum rate of 0.30 at 12 hrs (left front, DIM 150-180). The mean inter-milking interval for the 672 multiparous cows in this analysis was 9.2 hrs with a standard deviation of 1.9 hrs. For the 299 primiparous cows the mean was 8.3 hrs with a SD of 2.1 hrs.

Conclusions: This study has determined that gains of approximately 1.5% in milk production rate at the quarter level are associated with each decrease of an hour in the inter-milking intervals between 4 and 14 hrs. This trend is demonstrable for both primiparous and multiparous cows and is reasonably consistent across all three DIM windows analysed for all front and rear quarters.

Mammary epithelial cells, rather than professional immune cells dictate the pathogen-species specific immune reaction of the udder during mastitis

Juliane Günther¹, Mirja Koy², Anne Berthold¹, Hans-Joachim Schuberth¹, Hans-Martin Seyfert¹

¹Institute for Genome Biology, Leibniz Institute for Farm Animal Biology (FBN), Dummerstorf, ²Immunology Unit, University of Veterinary Medicine Hannover, Hannover, Germany

Objectives: The outcome of an udder infection (mastitis) largely depends on the species of the invading pathogen. Gram-negative pathogens, such as *Escherichia coli* often elicit acute clinical mastitis while Gram-positive pathogens, such as *Staphylococcus aureus* or *Streptococcus uberis* tend to cause milder subclinical inflammations. It is unclear which type of the immune competent cells residing in the udder governs the pathogen species-specific physiology of mastitis and which established cell lines might provide suitable models.

Materials and Methods: We profiled the pathogen species-specific immune response of different cell types derived from udder and blood. Primary cultures of bovine mammary epithelial cells (pbMEC), mammary derived fibroblasts (pbMFC), and bovine monocyte-derived macrophages (boMdM) were challenged with heat-killed *Escherichia coli*, *Staphylococcus aureus* and *Streptococcus uberis* mastitis pathogens and their immune response was scaled against the response of established models for MEC (bovine MAC-T) and macrophages (murine RAW 264.7).

Results: Only *Escherichia coli* provoked a full scale immune reaction in pbMEC, fibroblasts and MAC-T cells, as indicated by induced cytokine and chemokine expression and NF- κ B activation. Weak reactions were induced by *Staphylococcus aureus* and none by *Streptococcus uberis* challenges. In contrast, both models for macrophages (boMdM and RAW 264.7) reacted strongly against all the three pathogens accompanied by strong activation of NF- κ B factors. Hence, the established cell models MAC-T and RAW 264.7 properly reflected key aspects of the pathogen species-specific immune response of the respective parental cell type.

Conclusions: Our study shows that the models for mammary epithelial cells and fibroblasts, but not macrophages respond with distinctly graded immune reactions against each of the three pathogens. *Escherichia coli* but neither of the Gram-positive bacteria elicits in them synthesis of a strong and transient cytokine storm. This distinction is partly caused by the failure of MEC to activate TLR-mediated signaling upon challenges with *Staphylococcus aureus* or *Streptococcus uberis*. Hence, the pathogen species-specific norm of the immune response of MEC rather than that of macrophages appears to dictate the immune response of the udder early on after infection.

P01-001-177

Risk Factors For Peri-Parturient Farmer Diagnosed Mastitis In Canterbury Dairy Herds: Findings From A Retrospective Cohort Study.

Andrew Bates¹, Ian Dohoo²

¹Centre for Dairy Excellence, Vetlife, Geraldine, New Zealand,

²Department of Health Management, Atlantic Veterinary College University of P.E.I., Charlottetown, Canada

Objectives: To investigate cow level risk factors for peri-parturient cases of farmer diagnosed, clinical mastitis (CM) in spring calving pastoral based New Zealand dairy herds using a retrospective cohort study.

Materials and Methods: A retrospective longitudinal cohort study of 18,162 cows on 30 spring calving South Island New Zealand dairy farms was used to identify factors associated with the development of the first case of clinical mastitis in multiparous cows from 30 days before to 90 days after calving. All cows were dried off over the last two weeks of May 2012 using cephalonium dry cow therapy (Cepravin Dry Cow, MSD Animal Health, Upper Hutt, New Zealand).

Clinical mastitis was diagnosed by farm staff using changes in the udder, milk, or generalised illness.

Risk factors studied included age, breed, length of dry period, farm of origin, herd size, yield and cell count status 30-60 days before the end of the previous lactation, rainfall at calving and number of animals calving on the same day.

The effect of cell count status at the herd test before drying off, age, length of dry period and breed varied with time from enrolment. Plots of the cumulative estimated regression coefficients from an Aalen linear survival-time model were used to identify the form of the time varying effects.

A modified Cox Proportional hazards model with time varying effects for breed, age, length of dry period and cell count status 30-60 days before the end of the previous lactation was constructed by splitting the dataset at calving and 20 days after calving. For each of the time varying covariates, three covariates were created to reflect the varying effects of the predictor: early (30 days before calving to calving), mid (calving to 19 days post calving) and late (20 to 90 or more days after calving).

Results: Rainfall at calving, breed, age, length of dry period, yield and cell count status 30-60 days before the end of lactation were identified as significantly associated with an increased hazard of clinical mastitis around calving. Number of animals calving per day and herd size were not associated with an increased risk of clinical mastitis and there was a significant difference in the hazard of mastitis across farms.

The hazard of mastitis was 1.34 times higher for cows giving >1.5kgMS at the last herd test of the preceding lactation (95%CI=1.21-1.52) and 1.13 times higher if rainfall \geq 10mm on the day of calving (95%CI=1.01-1.30). Cross bred cows were predicted to have a lower hazard for CM with the hazard decreasing as the proportion of Jersey genetics increased. A cell count exceeding 150,000 cells/ml at the last herd test of the preceding lactation increased the hazard of CM by 1.60 (95%CI=1.39-1.84) in the first 20 days after calving and 1.95 (95%CI=1.67-2.27) 20-90 days after calving. The model predicted that compared to young (age=3 yrs) cows, cows aged 4-8 years had an elevated hazard of CM after 20 days in lactation (2.18, 95%CI=1.71-2.76), while cows older than 8 had an elevated hazard in all time periods at 2.98, (95%CI=1.73-5.14) before calving, 1.74 (95%CI=1.39-2.18) in the first 20 days of lactation rising to 4.09 (3.06-5.46) after 20 days.

A dry period of 112 days or more increased the hazard of mastitis in the first 20 days after calving 1.46 times (95%CI=1.24-1.73) but reduced the hazard 0.73 times for days 21-90 (95%CI=0.57-0.94).

Conclusions: This study confirms that the period around calving is the peak time for clinical mastitis diagnosis. In this study, 11% of multiparous cows were diagnosed with clinical mastitis from 30 days before to 90 days after calving and 38% of these cases were diagnosed within one week of calving. Only 3.4% of all cases were diagnosed during the dry period, affecting 0.4% of all cows. Although cow level studies can be useful in identifying variables that operate at this level

much of the variation in incidence of clinical mastitis stems from higher level variables operating at the herd level.

Thanks to John Moffat and MSD for supporting this project.

Molecular characterization of coagulase negative staphylococci from heifer intramammary infections and potential body site reservoirs

Pamela R. F. Adkins¹ John R. Middleton^{1*}

¹Veterinary Medicine and Surgery, University of Missouri, Columbia, Missouri, United States

Objectives: Coagulase negative staphylococcal (CNS) species are a common cause of subclinical mastitis in dairy heifers (De Vliegher et al., 2012). Currently, the relationship of body site colonization with these organisms and intramammary infection (IMI) in heifers is not well understood. The objective of this project was to determine if specific body sites were colonized with the same CNS species and strain type that were causing CNS IMIs in heifers.

Materials and Methods: Primiparous heifers (n = 100) at the University of Missouri Foremost Dairy were enrolled in the study. Pre-calving samples were collected at approximately 14d prior to expected calving date and included mammary quarter secretions and body site swabbing samples of teats, muzzle, perineum, and inguinal region. Swabbing samples were collected using gas sterilized electrostatic dusters (Swiffer®). At calving, mammary quarter foremilk samples were collected twice, at approximately 3-5 and 7-9 days postpartum, for bacterial culture and somatic cell counting. All body site swabbing samples were chilled on ice for transport and processed the same day. Swabbing samples were mixed with 10 ml of sterile saline, agitated, and plated on Mannitol Salt Agar (MSA). At 24h, plates were read and up to 10 staphylococcal colonies, including at least one of each morphologically distinct colony type, were sub-cultured onto Columbia Blood Agar (CBA). For all pre-partum secretions and milk samples, a 0.01 ml aliquot was plated onto CBA and primary identification was determined according to the National Mastitis Council guidelines (Hogan, 1999). Samples were considered to be culture positive if ≥ 1 colony were observed (≥ 100 cfu/ml). All staphylococcal isolates were banked in phosphate buffered glycerol at -80°C, and later speciated using DNA sequencing of the *rpoB* housekeeping gene (Drancourt and Raoult, 2002) and matrix-assisted laser desorption ionisation-time of flight (MALDI-ToF) mass spectrometry. Strain-typing was done using pulsed-field gel electrophoresis.

Results: The most common organisms identified at all three sampling points were CNS species. The most common CNS species identified in both pre-partum and post-partum samples was *Staphylococcus chromogenes*. Other common species identified were *S. agnetis* and *S. simulans*. A total of 2357 staphylococcal isolates were recovered from heifer body site samples. To date, 29% (682/2357) of these isolates have been speciated. After removing species represented more than once per body site sample for each heifer, a total of 241 of the 682 isolates have been characterized. The most commonly identified species from these body site samples were *S. chromogenes*, *S. haemolyticus*, and *S. devriesii*.

To date, PFGE strain-typing has been completed on all *S. chromogenes* isolates from five heifers. Multiple strains of *S. chromogenes* have been identified on all heifers characterized thus far. *Staphylococcus*

chromogenes strains isolated from the mammary gland were found to be 100% similar to a teat skin isolate on 3/5 heifers, to an inguinal isolate on 1/5 heifers, and to a teat skin and inguinal isolate on 1/5 heifers.

Conclusions: CNS is a common cause of subclinical mastitis in dairy heifers. In this study, *S. chromogenes* was the most common cause of CNS IMI, and was also commonly found in the inguinal region of pre-partum heifers. To date, preliminary strain-typing data has shown that *S. chromogenes* isolated from the mammary gland can be related to inguinal and teat skin strains. These body sites could be important sources of *S. chromogenes* for heifer IMI. Final results of this project will further the understanding of the epidemiology of CNS infections in dairy heifers and allow for the development and study of methods to control and prevent IMI.

P01-001-179

A new and simple method to deal with teat injuries

Franz Schleder^{1*}

¹Private Practice, Andorf, Austria

Objectives: Teat injuries are common in dairy cattle, around 2-3% are affected^{1,2}. They can be divided into two categories (external or internal injuries). They often result in premature culling of affected cows.

Surgery and treatment of these injuries has been described and discussed intensively^{3,4}. However the question whether complete rest (no milking) or temporary resting of the injured teat by temporary cessation of milking⁵ or continuous milking is not yet clearly answered and may vary from case to case.

This paper describes a new technique that allows a permanent milk flow alongside an undisturbed healing process of all types of teat injuries.

Materials and Methods: Cows with covered or open teat injuries are suitable to benefit from the permanent milk flow system. A silicon-like catheter (TEATflow) has been designed for that purpose. The described surgery of open lesions as well differs from traditional methods as no blood stasis is applied. Prior to intervention Oxytocin (10 I.U.) is administered intravenously to achieve an intensive milk drop down. Single suture knots are carried out to achieve only a slight, but careful wound closure. This procedure is aimed to result in a faster consolidation of fibrocytes for a undisturbed healing process. To avoid any internal milk teat pressure, that might disturb the accumulation of fibrocytes, milk is allowed to permanently exit the teat by the inserted catheter for 9 consecutive days. The insertion is eased by application with the help of the traditional Fuerstenberg-catheter. Penethamat-Penicillin (2 x 5 Mio I.E./day i.m.) is administered systemically to reduce concurrent teat infections. No further local antibiotic treatment is applied. Nine individual cow case studies are reported. Occurrence of clinical mastitis, restoration of complete milkability and evolution of somatic cell count (prior and

around eight weeks after treatment) are documented as potential success criteria. The mean somatic cell count of all cows was 140.000/ml prior to treatment.

Results: All cows fully restored milkability. One cow was infected by a clinical mastitis, which reflects a mastitis infection risk of 11%. The mean somatic cell count (SCC) at eight weeks after surgery was 167.500/ml, which reflects a 19% increase of prior SCC. Due to the limited numbers this is not statistically significant. Six cows showed an augmented SCC, whereas 3 cows revealed a reduced SCC. All nine cows are listed below as follows: Cow No., race, type of teat lesion (external/internal), SCC prior and after event, Clinical mastitis/No clinical mastitis.

Cow No. 1: Holstein, external, 85.000/135.000, No clinical mastitis

Cow No. 2: Hostein, external, 140.000/170.000, No clinical mastitis

Cow No. 3: Simmenthal, internal, 60.000/105.000, No clinical mastitis

Cow No. 4: Simmenthal, external, 220.000/180.000, No clinical mastitis

Cow No. 5: Holstein, internal, 115.000/95.000, No clinical mastitis

Cow No. 6: Simmenthal, external, 240.000/330.000, Clinical mastitis

Cow No. 7: Simmenthal, external, 70.000/90.000, No clinical mastitis

Cow No. 8: Holstein, external, 240.000/280.000, No clinical mastitis

Cow No. 9: Simmenthal, external, 90.000/80.000, No clinical mastitis

Conclusions: The new treatment and surgery method for all type of teat lesions offers a very practical, simple and easy way to successfully regain milkability. As the risk for clinical mastitis seems lower than reported elsewhere, the permanent milk fow system obviously seems to allow a faster and full healing process at a very low level of infection risk due to the permanent open teat canal.

P01-001-180

The Use Of Bacteriophage In The Prevention Of Bovine Coliform Mastitis

Michael Paros ^{1,*} and The Evergreen State College

¹Biology, The Evergreen State College, Olympia, WA, United States

Objectives: The objectives of the current study were to determine if a broad host-range bacteriophage cocktail could be made against mastitis-causing *E. coli*, evaluate coliphage activity in raw milk, determine whether our cocktail could reduce adhesion and invasion of mammary epithelial cells by chronic coliform mastitis strains, and test whether a phage based intramammary ointment can inhibit bacterial growth.

Materials and Methods: Seventy-four bacteriophages were initially isolated using 36 clinical coliform mastitis isolates from dairies in Washington State. Each individual phage preparation was then tested for its ability to suppress growth of the 36 clinical isolates using spot lysis tests. Four phages were selected from this group as candidates for a cocktail, based on their distinct broad host ranges against these mastitis strains. Restriction fragment length polymorphism analysis was performed to determine whether each phage in the cocktail was distinct and phage genomes were subsequently sequenced. To assess the effects of different doses of bacteriophage cocktail on the growth of *E. coli* isolates from New York and Washington State, optical density growth curves were generated for each bacterial strain. Total bacterial counts in raw milk were measured after twelve hours of incubation with the phage cocktail using a range of initial bacterial inoculant doses of an *E. coli* mastitis strain. An immortalized bovine mammary alveolar epithelial cell line, MAC-T, was used for adhesion, invasion, and internalization assays

through a modified gentamycin protection assay. The bacteriophage cocktail was emulsified with a bismuth-based teat sealant and its activity tested in liquid growth media.

Results: The bacteriophage significantly inhibited growth of 58% of the Washington State isolates and 54% of *E. coli* mastitis isolates from New York State, suggesting that the cocktail of phages had a broad spectrum of action against relevant strains from two distinct geographies. The ability to suppress bacterial growth of these isolates in a liquid growth media was not affected by the ratio of bacteriophage particles to bacterial cells (multiplicity of infection, MOI) which were tested. For those *E. coli* that were completely inhibited by the phage cocktail, an MOI as low as 10 had the same effect as 10 µg/ml of ceftiofur on the growth rate of *E. coli* over a twelve hour period using optical density measurements. Previous work with *Staphylococcus aureus* and phage K has shown that bacteriophage activity is inhibited in raw milk; however a 3.3-5.6 log reduction of *E. coli* growth was achieved when co-incubated with our phage cocktail in raw milk over a twelve hour period at physiologic temperature. Tissue culture plates pre-treated with approximately 10⁸ phage forming units (PFU) of our cocktail reduced mammary epithelial cell adhesion of three different chronic mastitis *E. coli* strains by 98.0, 99.6, and 99.7 percent. Intracellular invasion of mammary epithelial cells, as measured by the gentamicin protection assay, was reduced for the three strains by 88.3, 98.1, and 74.3 percent. When combined with a bismuth-based teat sealant, the phage cocktail was able to inhibit bacterial growth when challenged with 1.6 x 10³ CFU/mL of a clinical mastitis *E. coli* strain.

Conclusions: This in vitro study shows that a cocktail of bacteriophage can inhibit growth of common clinical coliform isolates and is active in raw milk. Bacteriophage can potentially prevent chronic *E. coli* infections by reducing adhesion and invasion of mammary epithelial cells and can be combined with a teat sealant as part of a dry cow treatment. Results suggest that a bacteriophage-based dry cow treatment could reduce the incidence of coliform mastitis in dairy cattle; however it must first be shown that a specific dose of bacteriophage can protect cows from experimentally induced *E. coli* mastitis without inducing an inflammatory reaction.

Impact Of The Use Of A Mastitis Multivalent Vaccine: A Field Study.

Adelaide Pereira ^{1,*}

¹Technical Services Department, SEGALAB. SA, 4490-258 Argivai, Portugal

Objectives: The coliform mastitis causes severe losses on dairy farms. Traditional strategies based on prophylaxis and control programs are not sufficient in some cases. New tools have emerged in order to increase the immunity of animals with emphasis on vaccines for mastitis. The aim of this study was to determine the effects on milk quality, on the infectious status of cows and the use of systemic antimicrobial therapy after the use of a mastitis multivalent vaccine (STARTVAC®, Hipra Laboratories SA, Spain) in a farm with serious problems of coliform mastitis.

Materials and Methods: The farm had on average 33 milking cows with excellent milking routines and good hygiene and management practices. The results of bacteriological samples of clinical and sub-clinical mastitis, in the year preceding the first application of the vaccine showed greater proportion of *Escherichia coli* (56%), *Streptococcus* spp. (17%) and Coagulase Negative *Staphylococcus* (CNS) (10%); the therapeutic

protocols used were expensive and with little effectiveness.

The vaccination program was initiated in August of 2012, with the three-week interval between the first and the second application, and repeated every three months, in lactating and dry cows and heifers.

Results: The number of treatments with systemic antibiotic therapy was 46% (6) in the previous year of vaccination and in the first year post vaccination was 11% (2); in the second year no systemic antimicrobial therapy was used in mastitis treatment. It was observed a reduction in annual average of somatic cell count (SCC) in the bulk milk, from 341.000 cells per milliliter (cells/ml) in the period 2011/2012, to 266.700 in the first year (2012/2013) and 202.000 in second year of vaccination (2013/2014).

A significant reduction in the percentage of chronic animal and new infections was observed, especially in the second year after immunization. However, the farm still had a risk period in winter, linked to climatic factors.

Conclusions: The results of the introduction of a multivalent vaccine for mastitis show a reduction of SCC in the bulk milk tank, a reduction in the number of new infections and chronic animal and a significant reduction of the antibiotic systemic therapy. The benefits obtained with the vaccination program justify their use and maintenance on the farm and must be considered on mastitis control programs.

Dry cow therapy on organic farms – Selection criteria

Klemens R. Kiesner¹ Nicole Wenthe¹ Volker Krömker¹

¹Microbiology, University of Applied Sciences and Arts, Hannover, Germany

Objectives: Antibiotic dry cow therapy (DCT) is a key component of dry cow management. According to the guidelines of organic farming the use of DCT is restricted and selective DCT is applied. Due to low cure and a high new infection rates the mastitis prevalence at calving is high on organic farms. To improve the udder health situation in the dry period and for successful selective DCT an accurate selection method is required to correctly identify infected animals. The objective of this study was to find cow level factors associated with intramammary infections (IMI) at dry-off and use the results to create a decision tree for dry cows.

Materials and Methods: The field study was carried out on five organic farms with a mean of 135 ± 35 German Holstein dairy cows located in Lower Saxony, Germany. 250 cows that were dried of between June and October 2014 were recruited to the study. No attempt was made to influence the dry cow management in the trial farms. Dry cow therapy was administered by the farm owners. Individual cows information was obtained from data of the dairy herd improvement (DHI) test. At dry-off, all cows had a California Mastitis Test (CMT) performed and udder shape, teat condition, cow cleanliness, body condition score and milk yield were recorded. Quarter foremilk samples were collected and cultured at dry-off and two times after calving. Until 100 d in milk clinical mastitis data of the cows were documented. Infection status at dry-off was used as the dependent variable in a generalised estimating equation (GEE) model.

Results: In 39.5% of quarters at dry-off and in 71.5% of quarters in the post partum control no microbiological growth could be detected. The most frequent isolated pathogens were coryneforms (23.4% dry off/ 11.0% post partum) and coagulase-negative staphylococci (16.7% dry

off/ 12.6% post partum). The new infection rate on quarter level was 17.6%, the cure rate was 81.3%. The GEE proved that a geometric mean of the somatic cell counts (SCC) > 100.000 cells/ml in the last three DHI records is significantly associated with an IMI at dry-off (OR: 15.425, 95% CI: 5.670 – 41.930, P<0.001).

Conclusions: The selection of infected animals at dry-off is the key to successful selective DCT. The present study showed that the geometric mean of the SCC in the last three DHI records can be used as an indicator for having an IMI at dry-off (Figure 1).

The cell wall component lipoteichoic acid of Staphylococcus aureus induces chemokine gene expression in bovine mammary epithelial cells

Yoshio Kiku¹ Yuya Nagasawa¹ Fuyuko Tanabe¹ Kazue Sugawara¹ Atsushi Watanabe¹ Eiji Hata¹ Tomomi Ozawa² Kei-ichi Nakajima³ Toshiro Arai⁴ Tomohito Hayashi¹

¹National Institute of Animal Health, NARO, Sapporo, ²National Institute of Animal Health, NARO, Tsukuba, ³Hokkaido Agricultural Research Center, NARO, Sapporo, ⁴School of Veterinary Medicine, Nippon Veterinary and Life Science University, Musashino, Japan

Objectives: Staphylococcus aureus is a major cause of bovine mastitis, but its pathogenic mechanism remains poorly understood. Among the virulence factors of S. aureus, the cell wall component lipoteichoic acid (LTA) has been shown to play a pathogenic role in infectious diseases through its involvement in biofilm formation, which promotes bacterial adherence to the host. The objective of this study was to evaluate the role of LTA in the immune or inflammatory response of S. aureus-induced mastitis.

Materials and Methods: To reveal whether LTA of S. aureus could induce immune or inflammatory response mediators in mastitis, we determined the gene expression profile of bovine mammary epithelial cells (BMECs) stimulated with purified LTA alone or formalin-killed S. aureus (FKSA) constituents containing all bacterial components, including LTA, using cap analysis of gene expression (CAGE). First, we analyzed differentially expressed genes (DEGs) in the profile of BMECs stimulated with LTA alone according to the CAGE results. Next, we analyzed the DEG profile in the BMECs stimulated with FKSA according to the CAGE results.

Results: A total of 59,441 transcriptional start sites (TSSs) of DEGs were induced by the LTA stimulation, including 41 up-regulated and 141 down-regulated genes. On the other hand, a total of 57,417 TSSs of DEGs were induced by the FKSA stimulation, including 54 up-regulated genes and 15 down-regulated genes. Seven common DEGs (IL-8, CXCL6, MX2, CCL2, IL-1α, NFKBIZ, and PTGS2) related to immune or inflammatory mediators were up-regulated under both LTA and FKSA stimulation. Three of these genes encode chemokines (IL-8, CXCL6, and CCL2) functioning as chemoattractant molecules for neutrophils and macrophages.

Conclusions: Using CAGE, we were able to clarify the indeterminate expression of chemokine genes that have not been previously identified under induction conditions mimicking bovine mastitis. The simultaneous detection of temporal expression patterns of pathogens and host cells, especially during S. aureus mastitis, will help to define the pathogenesis of mastitis and provide further insight into

the molecular cross-talk between pathogens and host cells. The CAGE results described herein have revealed novel mechanisms of chemokine induction by *S. aureus* LTA.

Effects of antibiotic dry cow therapy and internal teat sealant on milk somatic cell counts, clinical, and subclinical mastitis in early lactation

Helen Golder¹Ian J. Lean^{1*}

¹Scibus, Camden, Australia

Objectives: The objective of this study was to determine the efficacy of an internal teat sealant (TS; Teatseal; Zoetis Australia, Silverwater, NSW, Australia), when used in combination with antibiotic dry cow therapy (ADCT) administered at dry-off, on milk individual cow cell count (ICCC), milk production and components, and the incidence of clinical and subclinical mastitis in cows up to 60 days after calving, when compared to ADCT only.

Materials and Methods: Multiparous Holstein, Jersey, or Holstein cross cows (n = 2200) from 8 farms in Southern and Eastern Australia were randomly assigned to treatment of all 4 quarters with an ADCT alone or with ADCT and a TS (ADCT + TS) at dry-off in this randomized multi-site clinical trial. Milk yield, fat and protein percentage, and ICCC were measured at 14 ± 3 day intervals after calving for the first 60 days of lactation. The first measurement occurred between 10 to 24 days after calving. Clinical mastitis and health events were recorded from dry-off to 60 days in milk. Milk samples were collected from first cases of clinical mastitis and subjected to bacteriology. Log-transformed ICCC, ICCC weighted by milk yield, milk yield, and fat and protein percentage were analysed using a general linear mixed model for repeated measures, with the fixed effects of treatment group, time point, and the interaction of these effects, the random effects of farm, block, and animal, and the interaction terms for treatment group and farm, and treatment group, time point, and farm. The time to clinical mastitis (days post-calving) was analysed using survival analysis methods for censored data, with non-mastitis cases censored at the time of the last herd test up to 60 days post-calving. The presence or absence of subclinical mastitis post-calving (at least one ICCC of ≥ 250,000 cells/mL between 10 to 60 days post-calving) was analysed using a generalized linear mixed model with the fixed effect of treatment group, the random effects of farm and block, and the interaction term for treatment group and farm.

Results: Milk yield, ICCC weighted by milk yield, and fat and protein percentage were not affected by the interaction of treatment and time or treatment. Treatment with ADCT + TS at dry-off decreased the geometric mean ICCC by 11,500 cells/mL in the first 60 days of lactation, compared to use of ADCT alone (P = 0.021). Similarly, the geometric mean of the ADCT only group was 35% higher (95% CI: 5 to 72%) than that of the ADCT + TS group. The odds of at least one case of subclinical mastitis (ICCC ≥ 250,000 cells/mL) were 1.9 times higher (95% CI: 1.4 to 2.6%) with ADCT alone in the first 60 days of lactation, compared to the use of ADCT + TS. Use of ADCT + TS reduced the estimated incidence of at least one case of subclinical mastitis on all 8 farms, compared to use of ADCT alone. Only 4 cows that calved 40 to 100 days after dry-off had a first case of clinical mastitis in the dry period. Five percent of cows that calved 40 to 100 days after dry-off had a first case of clinical mastitis between 0 and 60 days in milk. Forty-three cases (5.7%) occurred in the ADCT group and 33 (4.3%) for the ADCT + TS group out of 1528

cows included in this analysis but this was not significantly different (P = 0.194). Proportional hazards estimates of survival showed there was no difference in the number of days post-calving to detection of first cases of clinical mastitis between the ADCT and ADCT + TS groups over the first 60 days postpartum (P = 0.153). The estimated hazard ratio for clinical mastitis over this period in the ADCT + TS cows was 0.70 (95% CI: 0.43 to 1.14%).

Conclusions: The combination of ADCT and TS provides benefits over ADCT use alone through improved prevention of the incidence of subclinical mastitis and reduced ICCC in the first 60 days of lactation. The prevention of mastitis is dependent on many factors in addition to dry-cow therapy, including aseptic dry-off technique, environmental and milking hygiene, and monitoring and management of cows, particularly during high risk periods. Adoption of the use of the combination of ADCT and TS may be beneficial for reduction of ICCC.

P01-001-185

Development Of New Intramammary Mastitis Treatment Containing Lasalocid

Kiro Petrovski¹Patricia Eats²Darren Trott¹Wen Wang³Stephen Page⁴Manouchehr Khazandi¹Hui San Wong¹Elizabeth Hickey¹Yunmei Song³Sanjay Garg³

¹The University of Adelaide, Roseworthy, ²The University of Queensland, Brisbane, ³The University of South Australia, Adelaide, ⁴Luoda Phrama, Sydney, Australia

Objectives: The objectives of this study were to test the potential of re-purposing ionophores for treatment of bovine mastitis using lasalocid as a model drug. The study aims were to improve the pharmacokinetic characteristics of the lasalocid using the solid dispersion delivery system, test its antimicrobial activity in vitro and preliminary cow-level assessment of the safety, preliminary withholding period and efficacy against mastitis using *Streptococcus uberis* challenge model. Lasalocid, a polyether ionophore has favourable for mastitis treatment due to the lack of clinically significant resistance and transmissible resistance elements.

Materials and Methods: Minimum inhibitory concentrations (MIC) were determined using the broth microdilution technique. Bacterial isolates were obtained from clinical cases of bovine mastitis occurring in Australian dairy cattle. In total, 57 gram-positive mastitis isolates were tested (*Streptococcus agalactiae* (12), *Staphylococcus aureus* (20), coagulase-negative staphylococci (14) and *Streptococcus uberis* (11)) plus 10 isolates of methicillin-resistant *Staphylococcus aureus* obtained from cases of infection in small animals.

The development of formulation followed few steps, namely determination of the solubility of lasalocid, preparation of the SD delivery system, and characterisation of the SD. The size reduction of the lasalocid alone and the SDs to micro-metre grade or to nano-metre grade was carried out by using sieves or a ball-mill and homogenizer. The tested formulations contained 150, 300, 400, 600 or 900 mg of the active.

For the cow-level experiments cows were in various stages of an active lactation. They were aged 2-10 years and four functional quarters, had no significant teat lesions, were in good health, had known somatic cell count history of less than 200,000 cells/mL and had not received antimicrobial or anti-inflammatory therapy within 14 days of the study commencement. For the safety and preliminary withholding period each

quarter of each cow was treated with the same dose of the formulation (e.g. 4 intramammary tubes per cow). For estimation of the efficacy only quarters that were diagnosed with mastitis were treated with the test or the reference product.

Results: Lasalocid demonstrated antimicrobial activity against the major Gram-positive mastitis pathogens including MRSA (MIC₅₀ range 0.5–2.0 µg/mL and MIC₉₀ of 0.5-4.0 µg/mL). However, lasalocid was not tested against Gram-negative pathogens capable of causing mastitis. In other work carried by this group we have demonstrated lack of efficacy of lasalocid against gram-negative pathogens.

The solubility test confirmed limited, ion-strength-dependent water solubility of lasalocid. Lasalocid has a low solubility in water but a significantly higher solubility in organic solvents such as DMSO and methanol.

The safety of the formulations differed between formulations, the size of the particles and the total dose of the active. A transient elevation of the somatic cell count after intramammary administration of any product was observed. The formulations that contained the largest dose of the lasalocid (900mg in all 4 quarters) caused mild depression and decreased appetite. The formulation containing Soluplus® was associated with a significant rise in the somatic cells and other clinical observation. The PVP-lasalocid-SD exhibited a faster distribution of active in milk than either nano- or micro-sized lasalocid estimated WHP of 5-6 milking.

All challenged quarters developed mastitis. The cure rates after the intramammary administration of 6 tubes in 3 days containing 150 or 300 mg PVP-lasalocid-SD provided effective treatment with a higher mastitis cure rate (66.7-100.0%) compared to the treatment with 3 tubes in 3 days of the reference cloxacillin-containing product (66.7%).

Conclusions: The results from this study indicate that polyether ionophores, using lasalocid as a model drug, can be successfully repurposed for treatment of bovine mastitis. The in vitro antimicrobial spectrum of lasalocid indicated that it can be used for treatment of bovine mastitis caused by the common gram-positive mastitis pathogens. The pharmacokinetic characteristics of the lasalocid using the SD delivery system study were improved. The PVP-lasalocid-SD demonstrated the best distribution and maintenance of the therapeutic concentrations and was safe. The preliminary withholding period of the PVP-lasalocid-SD formulation was acceptable.

Monensin continuous-release intra-ruminal device: effects on milk quality and ripened Parmigiano Reggiano cheese

Ludovica Mammi ¹·Mattia Fustini ¹Elena Bonfante ¹Alberto Palmonari ¹Luigi Grazia ²Andrea Formigoni ¹

¹DIMEVET, Dipartimento di scienze mediche veterinarie, ²DISTAL, Dipartimento di scienze e tecnologie agro-alimentari, University of Bologna, Bologna, Italy

Objectives: The objective of this study was to determine the influence of monensin continuous-release intra-ruminal device (Kexxtone®) used to reduce the incidence of ketosis in fresh dairy cows, on milk and cheese quality. Because Parmigiano Reggiano is an Italian DOP (Protected Designation of Origin) raw milk cheese, without additives and with a long ripening period, it should easily highlight any possible negative effect of the treatment on the component quality of the final product.

Materials and Methods: The device was administered to 33 cows, 21 days before parturition as label indications. After calving, cows that received the bolus became part of a treated group (T) while a control group (C) was set up with untreated cows. The groups were housed in two pens, fed the same total mixed ration and milked twice a day. Milk and lactoserum produced by the groups were kept separated and each group produced 2 cheese wheels (45 kg each) per day. During the 20 experimental weeks, morning tank milk and lactoserum were sampled twice a week, for a total amount of 35 samples per group. Group milk was analyzed for fat, casein, protein, lactose, titratable acidity (°SH), pH, clotting characteristics (LDG), Somatic Cell Count (SCC), urea and total bacterial count (TBC). Lactoserum was analyzed for titratable acidity, fermentative activities at 45, 52, 54°C (ΔSH) and total lactic acid bacteria count (UFC/ml).

All 552 cheeses produced during the trial (276/group) were examined at 6 months of ripening through x-ray analysis. An official expert of the Consortium of Parmigiano Reggiano evaluated the cheeses after 12 months from production, in order to highlight any defects. After 18 months of ripening, 48 cheeses (24/group) were analyzed by an expert panel in order to assess any sensorial differences among groups. The weight of every cheese was recorded after 36 hours and 18 months from production to determine the final cheese yield (kg cheese/100 kg milk).

Data were analyzed using one-way ANOVA with Tukey test for mean comparison (SPSS 17.0, USA). Statistical significance was fixed for p<0.05.

Results: Milk and lactoserum maintained the same quality in both groups with few significant differences: SCC was significantly lower in the treated versus the control group (135.3±34.6 vs 214.80±46.1, *1000/ml, p<0.01) and casein and fat yield (kg/cow/day) was higher for T than C group (0.92±0.04 and 1.29±0.11 vs 0.80±0.04 and 1.09±0.07, p<0.01). Daily individual cheese yield (kg cheese/cow/day) was 0.4 kg higher for T versus C cows (2.89±0.1 vs 2.42±0.1, p<0.01).

A significantly higher percentage of T cheeses showed absence of defects at x-ray analysis (93.8 vs 87.7 %, p<0.01) as well as at the Consortium's evaluation (98.5 vs 93.5 %, p<0.01).

Organoleptic analysis showed an overall comparable sensorial profile between cheeses with few significant differences. T samples showed a slightly slower ripening process indicated by higher intensity of butter and sweet aroma (3.2±0.4 and 3.5±0.3 vs 3.0±0.4 and 3.4±0.4, p<0.05) and lower rind and spicy flavours (2.0±0.4 and 1.8±0.4 vs 2.1±0.4 1.9±0.4, p<0.05). In addition, T cheeses had less intense, negative aromas, such as pungent, acetic and "stall", than C cheeses (2.1±0.4 vs 2.2±0.4, p<0.05).

Conclusions: These results suggest that treatment with a monensin continuous-release intraruminal device (Kexxtone®) in cows during dry off, doesn't affect milk, lactoserum or final cheese quality.

In addition, it showed a positive effect on somatic cell count and a good influence on ripened cheese. These positive implications could be associated with a general improvement of fresh cows' health status.

Effect of coffee ground silage in reducing somatic cell count in bovine subclinical mastitic milk

Kazuhiro Kawai ¹·Kana Kuruhara ¹Kiyoshi Akiyama ²Sachi Tanaka ³Yoshio Kiku ⁴Yutaka Matano ⁵Yasunori Shinozuka ¹

¹School of Veterinary Medicine, Azabu University, Sagamihara,

²Kanagawa Prefectural Livestock Industry Technology Center, Ebina,
³Faculty of Agriculture, Shinshu University, Minami Minowa, ⁴National
 Agriculture and Food Research Organization, Tsukuba, ⁵Menicon
 Company Limited, Nagoya, Japan

Objectives: Coffee grounds are a rich source of the antioxidant polyphenol, and so are known to have beneficial effects on the immune system as an oxygen scavenger. The present study investigated how the silaging of coffee grounds improved the palatability of cattle fodder, increased the antioxidant activity of cow milk, and altered immune cell kinetics, thereby reducing the somatic cell count in milk.

Materials and Methods:

Coffee ground silage

The coffee ground silage converted into feed for dairy cows using a new lactic acid fermentation technique was made with coffee grounds supplied from Starbucks stores in Japan.

Measurement of milk somatic cell count

Measurement was conducted on 44 quarters from 20 cows with subclinical mastitis. Eleven of the cows (22 quarters) received 1.5 kg/day of coffee ground silage and the remaining 9 cows (22 quarters) were assigned to the control group with no coffee ground silage. Milk samples were collected before and 1, 2, 3, and 4 weeks after introducing the feed, and somatic cell count in milk was measured using a DeLaval cell counter.

Measurement of antioxidant activity

Measurement was conducted on 11 cows with subclinical mastitis bred. Five of the cows received coffee ground silage and the remaining 6 cows were assigned to the control group with no coffee ground silage. Blood and milk samples were collected before and 1, 2, 3, 4, and 5 weeks after introducing the feed, antioxidant activity in the form of oxygen radical absorbance capacity (ORAC) was measured in blood and milk, and lipid peroxidation in the form of thiobarbituric acid reactive substances (TBARS) was measured in blood.

Milk immune cell kinetics

Testing was conducted on 12 cows with subclinical mastitis bred. Seven of the cows received coffee ground silage and the remaining 5 cows were assigned to the control group with no coffee ground silage. Milk samples were collected before and 1, 4, and 7 days after introducing the feed, and leukocyte populations in milk were analyzed using flow cytometry.

Results: Unlike the control group, which showed no significant decrease in somatic cell count in milk, the cell count at Week 5 in the coffee ground silage group had decreased significantly from baseline ($p < 0.05$). Blood and milk ORAC values were also significantly higher at Weeks 3, 4, and 5 in the coffee ground silage group compared to baseline levels ($p < 0.05$), and blood TBARS values at Week 5 were significantly lower in the coffee grounds silage group than in the control group ($p < 0.01$). Analysis of milk leukocyte populations up to Day 7 revealed a significant increase in CD4+ cells and CD14+ MHC class II+ cells at Day 1 versus at baseline in the coffee ground silage group ($p < 0.05$).

Conclusions: The study findings show that supplying coffee ground silage to dairy cows increases antioxidant activity in blood and milk and decreases the somatic cell count. Findings for immune kinetics up to Day 7 also suggested that coffee ground silage has an effect on the immune system.

Observation of Mastitis Parameters in farms using a Polyvalent Mastitis Vaccine. An update after 3 Years

Andrew Biggs¹ Daniel Zaldueño² Mandy Boddy³

¹Farm Team, The Vale Veterinary Group, Tiverton, Devon EX167RT, United Kingdom, ²Hipra, Girona, Spain, ³The Vale Veterinary Group, Tiverton, Devon EX167RT, United Kingdom

Objectives: Monitoring the dynamic nature and magnitude of the mastitis challenge, prevalence and incidence within the modern dairy herd is becoming common place around the developed dairy industries of the world. The iterative process of regular interpretation of prevalence data (Individual Cow Somatic Cell Counts [ICSCC]), incidence data (Clinical mastitis records) and how these data change over time both within lactation and over the dry period can give much information about the transmission patterns and likely origin and duration of intramammary infections within a dairy herd.

Materials and Methods: The initial aim of this project was to apply these diagnostic and monitoring techniques to three herds chosen for a high prevalence of *Staphylococcus aureus* over the 12 months prior to and during the 12 months of a rolling 3 month vaccination program with a polyvalent mastitis vaccine (Startvac, Hipra). After this initial observational period two of the herds decide to continue with the vaccination program.

All cows received 2 vaccine doses 3 weeks apart followed by a rolling policy of quarterly boosters. In calf heifers were batched to receive 2 doses 3 weeks apart with the second dose no less than 10 days prior to expected parturition. Heifers then joined the rolling 3 month booster program.

Data is compared at 6 month intervals from 12 months prior to and 36 months after initiating a whole herd vaccination policy.

Results: First 12 months (3 farms vaccinating)

The parameters observed were:

- *S. aureus* prevalence - using individual cow bacteriological culture of all cows in milk before and after the project.
- Clinical mastitis incidence.
- Reduction in clinical mastitis incidence in all 3 herds by 54%
- Routine monthly individual cow SCC data – using a 200,000 cells per ml threshold to indicate infection status.
- Reduction in proportion of infected cows in the herd (% cows > 200,000 cells per ml) by 4%
- Reduction in First infections in the 3 herds (high 1st cell count after parturition) by 71%. This effect was seen in both cows and heifers
- Reduction in New infections in two herds and increase in one herd (1st high SCC in current lactation but not 1st SCC after parturition)
- An estimation of cost benefit for the 12 month period of vaccination for the 3 herds was six times the cost of the vaccine.

From 12 to 36 months (2 farms vaccinating)

- Clinical mastitis incidence: both herds had an increase in clinical mastitis in the 12 to 18 months period after initiating vaccination. They had a likely lactation environmental outbreak of clinical mastitis. But they have subsequently returned to the improved mastitis rates seen subsequent to vaccination.
- The reduction seen in the first 12 months after vaccination for the proportion of infected cows and First infections was maintained in the next 24 months.

Conclusions: In this longitudinal study during three years of using a polyvalent mastitis vaccine despite some short lived fluctuations an improvement in the clinical mastitis and ICSCC was observed. It is important to remark that better results are obtained after 6 months using the rolling protocol - in common with other studies as the improvements take time to accumulate. Vaccination is a valuable tool to control *S. aureus* infections but it is important to remember that as with any control tool, vaccination is not a panacea and consistent good mastitis management is essential.

Milking-time testing in herds using Automatic Milking Systems

Håvard Nørstebo^{1,2}, Gunnar Dalen^{1,2}, Olav Reksen², Anne C. Whist¹

¹TINE Advisory service, TINE SA, Ås, ²Department of Production Animal Clinical Sciences, Norwegian University of Life Sciences, Oslo, Norway

Objectives: The aim of the study is to describe the variation of common milking-time test parameters for defined teat sizes and milk flow rates. Based on these results, we will simulate different milking-time test strategies to establish scientifically based milking-time test routines in AMS herds. In addition we aim to determine reference values for milking time test.

Materials and Methods: Milking-time tests on all teats on all cows (n=100) milked by two DeLaval VMS's at the Farm Animal Research Centre at Norwegian University of Life Sciences will be performed. The milking-time test will be performed using VaDia vacuum logging devices. Teat size, shape and condition will be registered before and after milking. Milk flow data will be collected from the milk meters. VaDia Suite data analysis tool will be used to calculate average milk flow, machine on-time, average vacuum level for the whole milking, during the peak-flow period and during overmilking, mouthpiece chamber vacuum during peak-flow period and number of vacuum fluctuations (www.biocontrol.no). Variance estimates for milking-time test parameters for the herd and for groups of cows will be included in a simulation model to determine the number of cow measurements that are needed to make inferences for the whole herd.

Data collection is ongoing, and the analysis will be conducted in February 2016.

In addition, a large number of results from milking-time tests performed on Norwegian farms by TINE Advisory service will be combined with udder health- and milk quality results from the Norwegian Dairy Herd Recording System to establish reference values for milking-time test parameters as mentioned above.

Results: The Milking-time test results will form the basis for a decision tool, used by Dairy advisers, to give advice regarding vacuum levels, teatcup liner and other milking machine settings. By including the whole herd, a description of in-herd variation and a simulation of selecting a smaller number of teats for testing is calculated. First, we will present herd mean and variation for different milking-time test parameters, such as short milk tube vacuum during peak flow, mouthpiece chamber vacuum, average milk flow and machine on-time, and we will present how these parameters vary between groups of cows with different teat sizes. Second, we will present how selection of different number/proportion of cows affects the herd level conclusions. Third, we will present relations

between milking-time test results and herd health and milk quality results to suggest optimum vacuum levels in different parts of the teatcup during milking.

Conclusions: As a conclusion, we hope to suggest a minimum number/proportion of cows to be included in a milking-time test to be able to give high-quality advice on herd level. We also hope to draw conclusions on the relationship between teat size and milking-time test results. This will form the basis for further research on the topic. In addition we hope to suggest reference values for milking time test.

Comments: Data collection is ongoing, and the analysis will be conducted in February 2016.

Bacterial carryover and contamination in composite milk samples from automatic milking systems

Gunnar Dalen^{1,2}, Håvard Nørstebo^{1,2}, Anne Cathrine Whist², Liv Synnøve Sølverød², Olav Reksen¹ and New approaches for management and breeding of dairy cows, in automatic milking systems – The AMS project

¹Department of Production Animal Clinical Sciences, Faculty of Veterinary Medicine and Biosciences, Norwegian University of Life Sciences, Oslo, ²Fag og System, Seksjon Melkekvalitet Helse Dyrevelferd Teknikk, TINE SA, Ås, Norway

Objectives: The principle method in Norway for collecting milk samples from dairy cows for bacteriological analysis is by aseptic sampling from all four teats separately. Since the introduction of PCR tests for udder pathogens, an increasing number of farmers with automatic milking systems (AMS) have started to use composite milk as sample material for bacteriological analysis of mastitis pathogens. Our objective is to see whether analysis of composite samples correctly predicts the presence of bacteria in the udder compared to aseptic sampling at quarter level.

Materials and Methods: We will collect composite milk samples for bacteriological analysis from cows in the research facilities at the Norwegian University of Life Sciences (SHF). SHF has two lactation pens with one DeLaval Voluntary milking system station (VMS) in each pen. Commercial automated samplers (DeLaval) will collect the composite milk samples. To minimize carryover, DeLaval has optimized the two VMS at SHF. Aseptic teat sampling will be manual.

100 cows will be sampled in both the AMS and manually at the same day. The samples will be frozen and shipped to the TINE Mastitis laboratory in Molde. Sample analysis will be with both bacteriological culturing and identification with the MALDI-TOF technology as well as with a PCR test kit for udder pathogens.

Results: Other studies have shown carryover from cow to cow in composite samples taken in both AMS (Løvendahl 2005) and conventional systems (Mahmmod 2014), both for milk components and bacteria. We expect to observe a level of bacterial carryover in composite samples collected via the two AMS in our setup. We will quantify this carryover and analyze the diagnostic value of testing composite milk samples instead of aseptic teat samples. This includes statistical analysis of variation in bacteriological diagnosis and the difference in diagnostic accuracy between composite milk samples on udder level and aseptic teat samples at quarter level.

Conclusions: We expect bacterial carryover from cow to cow in samples collected via the AMS. We also expect there to be environmental contamination of the composite milk samples and a lower level of detail from the analysis of composite milk than from the analysis of aseptic individual teat samples. It is imperative that diagnostic tests reflect the actual situation. If the diagnostic value of composite samples is too low to be of use, this is an important finding for the farmers sampling milk via the AMS.

Comments: Samples will be collected and analyzed in January 2016.

P01-001-191

Case study: Calculation of return on investment (ROI) after one year using a mastitis vaccination programme

Joaquim Baucells^{1,2,*}

¹Centre Veterinari de Tona, Tona, ²Universidad Autonoma de Barcelona, Barcelona, Spain

Objectives: To determine whether a mastitis vaccination programme meets its objectives in a dairy farm from the North of Spain, and to identify the benefits obtained on the basis of the calculation of return on investment (ROI).

Materials and Methods: A dairy farm with some 850 highly productive adult cows in the North of Spain, where the farmer presented us with the challenge of identifying whether the investment made in the implementation of a mastitis vaccination programme had been profitable. This was carried out after the consolidation of the vaccination programme and we present it below as an example and additional task of the work of the clinical veterinarian

In December 2013 a prophylactic vaccination programme of the whole adult herd was started with a mastitis vaccine (STARTVAC®, HIPRA). This decision was not taken as a therapeutic measure, which was not necessary, but as a farm excellence policy action and the pursuit of better technical and economic results based on the arguments put forward by the specialists (work organization, fewer cases of mastitis, less serious cases, better milk quality etc.).

Results: Technical results for 2013 (without mastitis vaccination) and 2014 (with vaccination) are presented in Table 1

Table 1: Main technical results of the implementation of the vaccination programme for 2013 (without mastitis vaccination) and 2014 (with vaccination)

Average number of cows (No.)	860	858
Mean monthly somatic cell count (cells/ml)	301	265
Linear Score (LS) based on individual SCC	3.04	2.66
Cases of mastitis (CM) (No. of cases per year)	505	400
Monthly mastitis	4.9 %	3.8 %
Standardized daily production (L/lact.cow /day)	34.40	35.12
Annual production (L/cow/year)	11,311	11,790
Quality premium (months with premium)	0	3
Quality premium (months with penalty)	7	2
Quality deduction (months with penalty)	0	0

Investment of 12,900 € in vaccination and its implementation facilitated lower costs associated with the treatment of clinical mastitis (-14,199 €), a higher milk value (+39,075 €) and a reduction in the SCC, which

contributed to the improvement in production (+11,269 €). The greatest return on this farm was the increase in quality premiums (61%) followed by the costs associated with mastitis (22%) and the reduction in SCC (17%). The ROI obtained after the investment was 500 % (64543/12900 x 100).

Conclusions: The ROI obtained after the investment was 500 %. On farms which do not have a quality premium, the ROI will be lower, but clearly positive at 197 % (25468/12900 x 100). The recommendation is to continue with the established vaccination programme with a reassessment next year.

P01-001-192

Case Study: Use Of Vaccination To Control Bovine Mastitis Caused By Klebsiella

Annemiek Veenkamp^{1,*} Martijn Seelie²

¹DAP Flevoland, Zeewolde, Netherlands, ²Hipra, Melle, Belgium

Objectives: Mastitis is an important animal disease causing decreased production and profits on dairy farms. J5 vaccines against gram negative pathogens have been used in the US for over 40 years. Since 2009 a polyvalent vaccine protecting against coliforms, Staphylococcus aureus and coagulase negative staphylococci (CNS) has been available in Europe (STARTVAC®).

The objective of this field trial is to find out on a farm with known Klebsiella mastitis problems if vaccinated cows become chronic after a clinical or subclinical infection with Klebsiella.

Materials and Methods: In a herd with 110 cows in milk, located in Flevoland in The Netherlands, during 2011 a problem with Klebsiella was diagnosed. Cows are housed in freestalls with dried manure solids as bedding material. Cows are milked in 2 robots (Lely A4) 3-3,2 times a day. After milking, a lactic acid product is applied as a spray.

All cows have been vaccinated since December 2014 including the heifers starting from four months before calving. Vaccinated animals received the first two doses in a four weeks interval. After this, a blanket vaccination protocol was done (single dose applied every three months for all cows and heifers). Animals with identified clinical mastitis were sampled in a sterile way before treatment, then a PCR test of the milk sample was performed

Every 3-4 months all cows with an elevated somatic cell count in two consecutive tests (cows >250.000 and heifers >150.000) were sampled from all quarters. Later samples were pooled on cow level and a PCR was performed.

Cows with a positive Klebsiella result on both a clinical or subclinical mastitis are followed in time in order to check the presence of Klebsiella.

Clinical mastitis cases are being treated with a combination of cefalexine and kanamycine and injected with a combination of trimethoprim and sulfadoxine. Subclinical mastitis cases are not treated.

Results: In 2014 there have been 31 cases of clinical mastitis. 15 cases were severe. Milk samples have been taken from 11 of these severe cases. Results were; 1 E. coli and 7 Klebsiella cases. Of these 7 Klebsiella cases 5 cows have either died or have been euthanized.

In 2015 there have been 17 cases of clinical mastitis. After sampling all of them, in 4 cases Klebsiella was found. From the subclinical mastitis cases (2015), in 4 cows Klebsiella has been found. Non of these Klebsiella cows have died or have been euthanized.

During resampling, 6 out of the 8 cows (75%), that had been positive for *Klebsiella* didn't show any *Klebsiella* anymore. In 2 cases (25%) *Klebsiella* was found in one or more samples during the resampling.

The "Defined Daily Dose Animal"(DDDA) for mastitis injectors from 1-1-2014 to 1-10-2014 was 1,07 and from 1-1-2015 to 1-10-2015 it is 0,66. The(total) DDDA for this farm from 1-1-2014 to 15-11-2014 was 4,45 and from 1-1-2015 to 15-11-2015 it is 3,29.

Conclusions: On a farm with known *Klebsiella* mastitis problems vaccination can help controlling disease by preventing quarters to become chronically infected. In addition cows suffer less severe clinical mastitis and cure rates have improved after vaccination.

However it is advised to track all confirmed *Klebsiella* mastitis cases. It is also important to sample high somatic cell cows on regular basis in order to quickly identify possible *Klebsiella* carriers.

Udder Health & Milk Quality

P01-001-194

Clinical efficacy of intramammary prednisolone treatment of naturally occurring clinical mastitis

Jantijn Swinkels¹;Gaelle Milon-Harnois²

¹Global Ruminants, Merck Animal Health, Madison, United States,

²Global Statistics, MSD Animal Health, Beaucouzé, France

Objectives: Most EU dairy cows affected with clinical mastitis, are, in addition to antibiotics, intramammary treated with prednisolone. Experimental studies support prednisolone treatment showing a reduction of clinical signs, but in such studies many variations between animals are excluded and treatment occurs within a few hours after challenge. The questions then is whether these effects can be translated to the field. Peer reviewed field study papers supporting prednisolone treatment in mastitis are scarce. Therefore, the objective of this study was to determine the clinical efficacy of prednisolone in clinical mastitis cases under field conditions.

Materials and Methods: The trial was a multi-centered, double blinded, randomized, controlled and performed in France according to GCP guidelines. One hundred and twenty cows with naturally occurring mastitis in a single quarter were randomly (SAS® software generated list) allocated to two treatment groups. The first group (Group 1) was treated intramammary, with 300 mg of cefapirin and the other group (Group 2) received 300 mg cefapirin plus 20 mg of prednisolone via the same route. Treatment schedule for both groups was 2x per day, after each milking with a 12 hour interval. Clinical examinations (rectal temperature, general condition, udder firmness, udder induration, udder pain, and milk quality) were performed at each morning and evening milking from day 0 to day 5 with a predefined clinical scoring system (0= normal, 1= light, 2=moderate, 3= severe)). Bacteriological analysis was only performed on pre-treatment milk samples of the affected quarter. Primary clinical efficacy parameters were the evolution of clinical signs during and shortly after treatment (4 days after the last treatment). Clinical condition of a cow was considered normal if clinical signs of clinical mastitis (milk aspect, udder and general condition) were absent, and the rectal temperature was < 39.5°C). Only cows affected in 1 quarter were enrolled, therefore the cow and quarter analysis are identical.

Results: Finally, a total of 117 cases were included in the trial from which 4 were excluded post-admission. This resulted in 113 cases included, 55 in Group 1 and 58 in Group 2. Reasons for post-admission withdrawal

were mainly deviations from the protocol, i.e. mastitis in a second quarter (n = 23), off protocol treatment during the trial period (n = 1).

Although all study data are collected, statistical analysis is currently performed, using a multi-variable logistic regression model including risk factors for clinical effects of prednisolone. Results will be available soon and can be presented at the WBC in Dublin.

Conclusions: The authors emphasize this is a unique and therefore important study for field practitioners to scientifically justify routine prednisolone treatment of clinical mastitis in the field. However, the deadline of the WBC abstract submission is a too early to draw final conclusions at this moment. Conclusions will be available for presentation at the WBC congress in Dublin.

Effectiveness and safety of a novel flunixin meglumine transdermal pour-on solution in the treatment of bovine mastitis

Siddartha Torres¹;Julien Thiry¹Vincent de Haas¹Philippe Brianceau

¹Albert Boeckh¹

¹Merck Animal Health, Madison, United States

Objectives: Anti-inflammatory drugs are commonly used as adjunct therapy to antibiotics to treat clinical mastitis, since many of the physiological and pathological changes associated with clinical mastitis are a result of the inflammatory response to infection. Flunixin is a NSAID used for the relief of pain and control inflammation and pyrexia associated with diseases of different origin and nature. A 50 mg/mL flunixin transdermal formulation (Finadyne® Transdermal) is available to be used in cattle. The objective of the study was to demonstrate the safety and effectiveness of flunixin transdermal in the treatment of clinical mastitis in dairy cows.

Materials and Methods: A total of 133 dairy cows, showing severe signs of mastitis, were randomly assigned to treatment with either the test product, flunixin transdermal or the negative control product, a red dye saline solution (to preserve masking), both administered topically along the dorsal midline . All animals received intramammary antibiotics and systemic antibiotics starting at 6 hours post-treatment. The animals were observed for clinical signs of disease for 6 hours post-treatment and daily for 5 consecutive days.

Results: The decrease in rectal temperature 6 hours post-treatment was greater in the flunixin group (-1.8°C) compared to the control group (-1°C). This difference was statistically significant (p<0.0001) and the superiority of the flunixin transdermal to the control was confirmed.

The alleviation of pain, firmness and swelling of the udder was also significantly greater at 6 hours (p<0.0001) and at 24 hours (p<0.05) after treatment initiation in the flunixin group compared to the negative control group. Rectal temperature and clinical index (general attitude and udder clinical signs) improved over time.

Neither flunixin nor control had a negative influence on the health status, confirming that flunixin transdermal is safe.

Conclusions: The new 50 mg/mL flunixin transdermal demonstrated strong anti-pyretic effect and anti-inflammatory properties, providing a convenient and suitable adjunct therapy to anti-infectives used in cases of mastitis infections in cattle to reduce pyrexia and to alleviate clinical signs of pain, firmness and swelling of the udder.

Udder Health & Milk Quality

P01-001-196

Prevalence, Colony-Forming Units, And Antibiotics Sensitivity Of Klebsiella Pneumonia In Mild Cases Of Mastitis

Takeshi Tsuka¹ Keiji Hayashi² Hiroichi Ozaki¹ Toshiyuki Murase¹ Yusuke Murahata¹ Kazuo Azuma¹ Tomohiro Osaki¹ Norihito Ito¹ Yoshiharu Okamoto¹ Tomohiro Imagawa¹

¹Tottori University, ²Tottori Prefectural Federation Agricultural Mutual Aid Association, Tottori, Japan

Objectives: Coliform is reportedly one of the common causative bacteria frequently isolated from >50 % of mild cases of mastitis, which secrete a variety of forms of denatured milk but have no systemic signs. However, the previous reports describing clinical correlation between simple intra-mammary infection of *Klebsiella pneumoniae* (K.p.) and occurrence of mild signs of mastitis have been rare. The purpose of the present study is to clarify the clinical implication of infection with K.p. associated with mild cases of mastitis from the prevalence, colony-forming units, and antibiotics sensitivity of K.p.

Materials and Methods: Specimens were 2075 milk samples of 855 mild cases of mastitis breeding in 37 farms in Tottori prefecture between October 2012 and March 2015, and 31 specimens obtained from cows with peracute mastitis. K.p. was isolated, and measured the bacterial counts in milk (\log_{10} CFU/ml) on MCIC agar under incubation at 37°C for 24 h, and identified using the API 10 test (BioMérieux, Marcy l'Etoile, France). Antimicrobial susceptibilities of the isolates to 16 types of antimicrobial agents were determined by the disc diffusion method in accordance with the guidelines of the Clinical Laboratory Standards Institute. Prevalence and bacterial counts of K.p. in milk samples were statistically compared between months using a chi-squared test, and a one-way analysis of variance test. A milk sample, in which K.p. was isolated 5.0 \log_{10} CFU/ml, was defined as a high isolated milk (HM). The prevalence of HMs were compared between months with a chi-squared test. Prevalence of antimicrobial resistant K.p. strains for each 16 antimicrobial agents were compared between cows with mild mastitis and peracute mastitis, and between 4 farms, where >10 K.p. strains were isolated from 2012 to 2015, with a chi-squared test. A p value of < 0.05 was considered statistically significant.

Results: K.p. was totally isolated in 155 of 2075 milk samples. The monthly prevalence of K.p. ranged from 3.6 to 13.7 %, and was significantly ($p < 0.05$) higher in July (12.4 %), and September (13.7 %). Averages of the bacterial counts of K.p. in milk samples were beyond 5.0 \log_{10} CFU/ml between February and October, although there were no significant differences between months in the K.p. CFU/ml of milk. The monthly prevalence of HMs averaged 56.0 % (ranging from 0.0 to 83.3 %), and was significantly ($p < 0.05$) higher in Jun (83.3 %) than in other months. Mild cases of mastitis had a comparatively higher prevalence of antimicrobial resistant K.p. strains for 5 types of cephalosporin antibiotics (used on screening tests for ESBL-producing bacteria) than those in the cows with peracute mastitis: the prevalence in the cows with mild mastitis ($n = 155$) and peracute mastitis ($n = 31$) was 8.0 % and 4.0 % for ceftazidime, 16.6 % and 4.8 % for ceftriaxone (CTRX), 18.5 % and 4.8 % for cefotaxime (CTX), 11.9 % and 4.8 % for cefpodoxime, and 9.3 % and 4.8 % for aztreonam (AZT), respectively. Of 4 farms, a farm had a significant ($p < 0.05$) higher prevalence of antimicrobial resistant K.p. strains for CTRX (36.4 %), CTX (36.4 %), AZT (27.3 %), and minocycline (16.7 %) than the other farms (resistance rates of 0.0 to 14.8 % for CTRX, 0.0 to 16.4 % for CTX, 0.0 to 10.0 % for AZT, and 0.0 to 1.6 % for minocycline). Another farm had a significant ($p < 0.05$) higher prevalence of antimicrobial resistant K.p. strains for tetracycline (83.3 %) than the other farms (25.0 to 50.0 %).

Conclusions: The present data suggests the following factors for mild cases of mastitis due to intra-mammary infection of K.p.: 1) A high-temperature and humidity particular in Japan relates to increases in the prevalence and bacterial counts.; 2) Higher intra-mammary K.p. infection is not always absolutely required for determining the severity of mastitis.; 3) Development of antimicrobial resistant K.p. may correlate with difficulty in healing, and chronicity, following occurrence of mild mastitis.; 4) Differences between farms in the infection patterns of antimicrobial resistant K.p. may be due to inappropriate use of antibiotics on particular farms.

Comments: Intra-mammary infection of *Klebsiella pneumoniae* was commonly focused on occurrences of peracute mastitis. However, the present study indicates that intra-mammary infection of *Klebsiella pneumoniae* is one of the important factors for occurrences of mild mastitis by long-term bacterial examinations for a great many specimens. Especially, mild cases of mastitis caused by intra-mammary infections of K.p. predict to be an important problem on herd health, and public health, based on the higher intra-mammary infection rate of *Klebsiella pneumoniae*, and the higher prevalence of antimicrobial resistances.

Udder Health & Milk Quality

P01-001-198

Characteristics of mastitic mammary secretions from Holstein cows at 8–12 days before parturition

Atsushi Watanabe¹ Eiji Hata¹ Tsunao Hirai²

¹Dairy Hygiene Research Division, National Institute of Animal Health, National Agriculture and Food Research Organization, Sapporo,

²Animal Research Center, Agricultural Research Department, Hokkaido Research Organization, Shintoku-cho, Hokkaido, Japan

Objectives: In dairy cows, the incidence of new intramammary infections increases around and during the dry period of a lactation cycle. An intramammary infection during the dry period is considered to cause mastitis in the early lactation stage, and incidence of crisis of clinical mastitis actually increases after calving. Diagnosis of mastitis before calving will lower the loss of milk production in the early lactation stage if measures are undertaken before the beginning of lactation. The objectives of this study were to evaluate the relationship between intramammary infection and elemental characteristics of mammary secretion at the late dry period.

Materials and Methods: Mammary secretions were collected from 24 quarters of 6 Holstein cows at approximately 10 days (8-12 days) before parturition; the cows were raised in local farms in Japan. No obvious clinical signs of inflammation (redness, swelling, heat or pain) were found on their surfaces of udders. The mammary secretions were subjected to microbiological cultivation tests for identifying mastitis causative pathogens and counting somatic cells by direct microscopic observation, following macroscopic observations such as viscosity, color, including contamination of the blood pigment or red blood cells, and presence of gelatinous fibrin, milk clots, or flakes. Viscosity was divided into 3 classes, glutinous starch syrup or colostrum-like, normal milk-like, and serous fluid-like, and mammary secretions that showed starch syrup or colostrum-like viscosities were determined as normal. Concentration of serum albumin was determined using single radial immunodiffusion after removing somatic cells, fat, and fibrin from the mammary secretions by centrifugation.

Results: Macroscopic abnormalities were observed in 16 of 24 mammary secretion samples, and abnormal viscosity was found in all the

samples, except samples in which ostensible viscosity was increased by gelatinous fibrin. Mastitis causative bacteria (environmental streptococci, coagulase-negative staphylococci or *Corynebacterium bovis*) were isolated from 14 samples, and some macroscopic abnormalities were found in all the samples. In all of the abnormal mammary secretions, somatic cell counts and serum albumin concentration were apparently increased, identifying the occurrence of mastitis in the mammary glands.

Conclusions: At approximate 10 days before parturition, an intramammary infection caused mastitis, and mammary secretions showed abnormal macroscopic findings. Infiltrations of somatic cells and serum albumin were found in the mammary secretions. Lower viscosity of the mastitic mammary secretion could be caused by dilution with exuded serous fluid. Diagnosis of mastitis before parturition may help in controlling mastitis during the periparturient period.

P01-001-199

Early Lactation Extended Therapy Against *Staphylococcus Aureus* Intramammary Infections In Heifers: A Randomized Controlled Trial

Sophia Skoulikas¹, Jean-Yves Perreault², Simon Dufour^{3,4}, Jean-Philippe Roy^{1,4}

¹Sciences Cliniques, Université de Montréal, Saint- Hyacinthe, ²Clinique Vétérinaire Centre du Québec, Notre-Dame-du-Bon-Conseil, ³Université de Montréal, ⁴Réseau Canadien de Recherche sur la Mammite Bovine et la Qualité du Lait, Saint- Hyacinthe, Canada

Objectives: Once firmly established, *S. aureus* intra-mammary infections (IMI) are very difficult to cure. We could hypothesize that higher cure rates could be obtained in infected first parity cows treated promptly during the early lactation period. The general goal of this study was to evaluate the effect of an extended therapy using pirlimycin at calving for first lactation cows infected by *S. aureus* and identified using Petrifilm™ Staph express (STX) plates. The specific objectives were to assess cure rates in the treatment group and to assess test characteristics of the STX when used to identify infected quarters in early lactating heifers.

Materials and Methods: Study design was a randomized controlled trial. All first lactation cows with 4 functional quarters coming from a convenient sample of 21 dairy herds in the Drummondville area (Qc, Canada) and calving between May 2014 and December 2015 were enrolled. Quarter milk samples were collected from heifers in the first 10 days after calving. Quarter milk samples were diluted 1:10 with sterile water and inoculated on STX plates which were placed in an incubator at 35°C for 24h. After 24h, each Petrifilm was read by a trained technician and, when colonies were detected, a confirmation disk (DNase) was used to confirm *S. aureus* diagnostic. All presumptive colonies of *S. aureus* identified on STX were confirmed as such in a reference laboratory using standard methods. Positive quarters were randomly allocated to the control or treatment group using a random number generator. Cows in the treatment group received an extended therapy using pirlimycin: the producer administered 1 intramammary tube containing 50mg of pirlimycin hydrochloride (Pirsue®) in each infected quarter, once a day for 8 consecutive days, using a sterile technique. The control group remained untreated. Milk samples of the infected quarters in both groups were taken on day 7, 14 and 21 following treatment allocation and sent frozen to the reference laboratory where they were analysed using standard methods. A bacteriological cure was defined by the absence of *S. aureus* in the 3 post-treatment milk samples.

Results: For these preliminary analyses, effect of treatment group on odds of cure of the IMI was computed as odds ratio (OR) and 95% confidence intervals (CI) using methods for 2x2 tables. Recruitment of first parity cows in the trial is still ongoing. Up to now, 472 heifers were sampled and a total of 68 were confirmed infected by *S. aureus* in the first 10 days after calving indicating a prevalence of *S.aureus* IMI of 14.4% (95% CI: 11.5, 17.9). Thirty-six infected heifers were randomly allocated to the treatment group and 32 were allocated to the control group. The observed cure rates so far were 67% (24/36) and 41% (13/32) in the treatment and the control group, respectively. Preliminary analyses indicated significantly higher odds of cure (OR: 2.9; 95% CI: 1.1, 7.9) in treated cows compared to the control group. Regarding accuracy of STX plate for identifying *S.aureus* infected quarters in early lactating first parity cows, 27% (25/93) of the positive STX were found to be false positives when compared to the bacteriological results from the reference laboratory.

Conclusions: Preliminary results show that a high cure rate can be achieved with the proposed extended treatment when instigated within two weeks of calving. An unexpected high self-cure rate was observed in the control group. Petrifilm STX can be used to detect *S. aureus* infected heifers early in lactation, but a substantial number of false positive results should be expected. The RCT will be completed and then fully analysed. Additional analyses will also be conducted to try to propose better guidelines for STX interpretation to reduce the proportion of false-positive in the future.

How farmers experience the introduction of selective dry cow therapy

C.G.M. Scherpenzeel¹, S.H.W. Tijs¹, I.E.M. den Uijl¹, I.M.G.A. Santman-Berends¹, A.G.J. Velthuis¹, T.J.G.M. Lam^{1,2}

¹GD Animal Health, Deventer, ²Dept. Farm Animal Health, Utrecht University, Utrecht, Netherlands

Objectives: In January 2013, selective dry cow therapy (SDCT) became obligatory in the Netherlands. Experimental studies were done on the effect of SDCT on udder health (Scherpenzeel et al., 2014). How SDCT was executed in practice, and how farmers experienced SDCT, was unknown, while it is important for quantifying the effect of this major change in mastitis management. Therefore, this study aimed to provide insight into the level of implementation of SDCT in 2013 in the Netherlands, the methods used for selection of cows for DCT, SDCT in relation to mastitis incidence and antimicrobial usage, and the attitude and motivation of farmers towards SDCT.

Materials and Methods: Data on clinical mastitis, bulk milk somatic cell count (BMSCC) and antimicrobial usage were collected prospectively in 179 farms, and data on subclinical mastitis were available from 177 farms. Farms were classified based on the percentage of cows on the farm that were dried off with antibiotics. Dry cow management and the mindset of 179 Dutch dairy farmers regarding the implementation of SDCT in the year 2013 were evaluated retrospectively using a detailed telephone questionnaire, that contained items about application of DCT, technical knowledge on SDCT, attitude towards DCT, and items on dry period management and farmer characteristics. There were open questions, questions with pre-defined answer categories, as well as statements that the farmers rated on a 5-point Likert scale. The relationship between the

level of SDCT, antimicrobial usage and udder health parameters was analyzed using a Kruskal-Wallis analysis.

Results: During 2013, 44 farmers (25%) applied blanket dry cow therapy (BDCT) and 135 (75%) applied SDCT. Of all participants 113 farmers (64%; group 1) dried off >60%, and 64 farmers (36%; group 2) ≤60% of cows with antibiotics.

There was no significant difference in the incidence rate of clinical mastitis, nor in the prevalence of subclinical mastitis in heifers, between the groups 1 and 2. Group 2, however, had a significant higher BMSCC ($p < 0.004$) and a higher incidence of subclinical mastitis in multiparous cows ($p < 0.04$) than group 1. Between the groups a difference in total antimicrobial usage was found, obviously due to a difference in use of dry cow antibiotics. There was no difference in antimicrobial usage for intramammary treatment of clinical mastitis between both groups.

Conclusions: The mindset of farmers towards SDCT was surprisingly positive, although farmers were concerned about the udder health situation and were uncertain on what to expect. Nevertheless, most of them indicated they understood the reason of the ban on preventive use of antibiotics, and acted proactively towards the decrease of the use of dry cow antibiotics. Based on differences in the udder health situation per farm as well as differences in the attitude of farmers, practical implementation of SDCT on the dairy farm needs clear, scientifically based directives as well as a custom made advice.

Staphylococcus aureus genotype B: sanitation of positive dairy herds using a qPCR approach

Carlotta Sartori¹, Ivana Ivanovic¹, Hans Ulrich Graber¹

¹Agroscope, 3003 Bern, Switzerland

Objectives: *Staphylococcus* (*S.*) *aureus* is one of the most important pathogens responsible for intramammary infections (IMI) in cattle worldwide. *S. aureus* genotype B (GTB) is contagious (herd problems) whereas the remaining genotypes infect individual cows and quarters. *S. aureus* GTB causes high economic costs and is a concern for food safety (enterotoxin production). Eradication of this pathogen in Swiss dairy herds would be, therefore, highly beneficial. For this reason, a highly sensitive and specific qPCR assay to detect *S. aureus* GTB in milk was applied for sanitizing GTB-infected herds and was compared to sanitation using classical bacteriology.

Materials and Methods: Using bulk tank milk, we selected 18 herds positive for *S. aureus* GTB. They were randomly allocated to one of 2 sanitation groups: for the “bacteriology group” (9 herds), phenotypic bacteriology was performed on aseptically collected milk samples, while for the “qPCR group” (9 herds) the qPCR approach (Boss et al., 2011; Voelk et al., 2014) was applied for the analysis of clean, non-aseptic milk samples. The milk of all lactating cows was periodically analyzed during the whole sanitation time (9 months) at different time intervals for the two sanitation groups. For the “bacteriology group” the classical sanitation procedure was applied as implemented by Kirchhofer et al. (2011). For the “qPCR group”, the milk of the 4 quarters of each cow was analyzed

monthly. For both sanitation procedures, cows were allocated to 3 groups: group 1 (GTB negative), group 2 (GTB unclear: cows after calving, after a therapy or new on farm) and group 3 (GTB positive). Cows of group 1 were milked first, cows of group 3 last in the milking order. A limited number of on-farm measures concerning milking hygiene and management were implemented on all farms during the whole observation period. Beneficial properties of the qPCR method are: i) it requires only clean milk samples; ii) single milk sampling is adequate for detection of IMI caused by *S. aureus* GTB; iii) high laboratory throughput.

Results: In general, GTB sanitation of herds was possible for both the “qPCR” and the “bacteriology” group. Sanitation by qPCR allowed sampling of large herds (>120 cows) by one person without disturbing the milking process, and the samples of these herds were analyzed within 2 to 3 days. In contrast, sanitation by standard bacteriology was reasonable for herds up to 30 cows as the aseptic sample collection and the laboratory work are very time consuming. After having learnt novel biological phenomena on 2 farms, the rate of new infection was zero for all the remaining herds during the whole sanitation period of the “qPCR group”. All herds could be sanitized if the farmer was willing to cull cows with treatment failure. The same was also true for the “bacteriology group”.

Conclusions: Sanitation of GTB-positive herds can be successfully performed by both analytical methods. However, sanitation by the bacteriological method is restricted to small herds under research conditions. In contrast, sanitation by qPCR is simple, suitable for routine purposes and may include even large herds as sample collection is massively facilitated and as analysis in the laboratory is fast. These beneficial properties of the qPCR method allow for the first time to envisage area-wide sanitation of contagious mastitis caused by *S. aureus*.

Factors Associated With Marketed Milk Production Recovery After Treatment Of Naturally Occurring Acute Coliform Mastitis

Yasunori Shinozuka¹, Sohei Kaneko², Tomoyasu Kurose³, Aiko Watanabe¹, Kana Kuruwara¹, Kazuhiro Kawai¹

¹Azabu University, Sagamihara Kanagawa, ²Fuchu Veterinary Clinical Center, NOSAI Hiroshima, Fuchu, Hiroshima, ³Kitahiroshima Veterinary Clinical Center, NOSAI Hiroshima, Hatsukaichi Hiroshima, Japan

Objectives: Milk production loss after recovery from acute coliform mastitis causes major economic losses for dairy industries. Therefore, an effective treatment that minimizes the adverse impact of coliform mastitis on milk yield is urgently required. Declines in milk production and composition are caused by multiple factors, including cow factors, microorganisms, and treatments, but the influence of each factor has not been determined. The aim of this study was to identify possible risk factors for subsequent milk loss after recovery from naturally occurring acute coliform mastitis.

Materials and Methods: Fifty-three Holstein-Friesian cows were enrolled in this study. All were diagnosed with acute coliform mastitis that was classified as moderate at the first examination and cured 14 days later. Survey target data including cow age, days in milk, systemic and local signs, and initial treatment were collected. Initial treatment data included body temperature, systemic nonsteroidal anti-inflammatory

drug (NSAID) administration, systemic and local antibiotic administration, systemic and local steroid administration, and mammary irrigation regimen after frequent milking out. Systemic and local antibiotics were categorized into three groups: none, fluoroquinolones (FQs), and others. Thirty days after clinical cure, owners were interviewed about milk yield recovery and marketing of milk.

The main outcome measure was milk production in a treated quarter (marketed milk or complete loss). The differences between outcome and continuous/categorical variables were examined first. A logistic regression model was used to analyze the strength of the associations. Continuous variables (age, days in milk, and body temperature) in both groups were examined using the Mann-Whitney U test. Categorical variables were assessed by Fisher's exact test and then chosen based on their statistical significance ($P < 0.25$).

The Kaplan-Meier method with the log-rank test was used to compare survival (time to event) curves between outcomes.

Results: In the analyses of continuous variables, no statistically significant differences were noted. In the analyses of categorical variables, three categorical variables (systemic administration of antibiotics, intramammary administration of antibiotics, and mammary irrigation) were selected for multivariate logistic regression analysis. Systemic administration of FQ was the only independent predictor associated with outcome, compared with the group that received no antibiotic (odds ratio, 21.7; 95% confidence interval, 1.48-317.00). There were no significant differences in any other variables. Survival curves were significantly different between outcomes (harvesting of marketed milk or complete loss of milk in a quarter) ($P = 0.046$, time-to-event analysis, log-rank test).

Conclusions: Systemic administration of FQ as the initial treatment of acute coliform mastitis classified as moderate was significantly associated with the prevention of subsequent milk loss. Though statistical association does not guarantee causation, our results can be taken into account in future studies. This knowledge will allow practitioners to provide appropriate treatment, and infected cows may be able to live longer by maintaining productivity.

The Effect of Supplementation with Organo-Modified Clinoptilolite on the Colostrum Quantity and Quality in Holstein-Friesian Heifers

Natalija Fratrić¹, Milica Stojić¹, Vesna Ilić², Marijana Buač², Dragan Gvozdić³, Radojica Djoković⁴, Marko Cincović⁵, Jasna Bošnjak⁶, Marko Vasiljević⁶

¹Department of Physiology, Faculty of Veterinary Medicine, University of Belgrade, ²Institute for Medical Research, University of Belgrade, ³Department of Pathophysiology, Faculty of Veterinary Medicine, University of Belgrade, Belgrade, ⁴Department of Anatomy and Physiology, Faculty of Agriculture, University of Kragujevac, Čačak, ⁵Department of veterinary medicine, Faculty of Agriculture, University of Novi Sad, Novi Sad, ⁶Patent co, Belgrade, Serbia

Objectives: Providing adequate amount of high quality colostrum to the newborn calves is an important issue in dairy farming. Colostrum from the first lactating dairy cows on our commercial dairy farms is usually discarded to the general opinion that quantity and quality is insufficient to provide adequate passive immunity transfer. In recent years the use of natural and synthetic zeolites in animal nutrition has increased. The

objective of this study was to determine the effect of supplementation with organo-modified clinoptilolite on the colostrum quantity and quality in Holstein-Friesian heifers.

Materials and Methods: Total number of 19 Holstein-Friesian heifers at the commercial dairy farm were daily supplemented with 150 g of organo-modified clinoptilolite (Minazel plus, Patent.co, Belgrade, Serbia) during the late pregnancy (25±5 days before parturition until 2 days after parturition). Control group of animals were 16 non supplemented Holstein heifers. Total volume of colostrum from 1-4 milkings (12 hours interval, first 48 hours after parturition) was recorded and 200 ml of colostrum samples were collected and stored at -20°C until analysis. The colostrum immunoglobulin G (IgG) concentration was determined using radial immunodiffusion (RID) method (RID kit, The Binding Site group Ltd, Birmingham, UK), and total mass of colostrum IgG was calculated. Statistical analysis was performed using GraphPad Prism statistical package, and after testing of normality the differences between mean values of all data obtained from supplemented and control group were tested using unpaired t-test (or unpaired t-test with Welch's correction, if normality test was negative). Regression exponential curves for colostrum IgG concentrations were determined and tested.

Results: Highest volume of colostrum was obtained at the 4th milking and lowest at 2nd milking in both groups (6.3±1.7L in both groups at 4th milking; 3.4±1.7L and 3.9±1.7L in control and supplemented group at 2nd milking, respectively). There were no significant differences in the total volume of colostrum at 1-4 milking between supplemented and control group of animals. However, colostrum IgG concentration and total mass were significantly higher at the first and second milking in supplemented animals (IgG concentration: 184±40g/L:130±34g/L, 95±54 g/L:57±30 g/L, $p < 0.05$; IgG total mass: 689±393g:436±222g, 301±156g:184±109g, $p < 0.05$; 1st and 2nd milking in the supplemented and control group, respectively). There was a significant difference between regression curves of the mean IgG concentration at 1-4 milking between supplemented and control group ($y = 381.9e^{-0.83x}$, $R^2 = 0.985$; $y = 300.2e^{-0.89x}$, $R^2 = 0.996$, $p < 0.05$, supplemented and control group, respectively).

Conclusions: The results of this study indicate that colostrum quantity (total volume) in Holstein-Friesian heifers is not significantly affected by the supplementation with organo-modified clinoptilolite. However, colostrum quality (assessed by concentration and total mass of colostrum IgG) are significantly increased by supplementing Holstein-Friesian heifers with the organo-modified clinoptilolite during late pregnancy.

P01-001-204

Genotypic diversity and lineage-specific expression of virulence traits in bovine-adapted Staphylococcus aureus

Orla Keane¹,

¹Teagasc, Grange, Dunsany, Co. Meath, Ireland

Objectives: The objective of this study was to determine the genotypic diversity of bovine-adapted Staphylococcus aureus isolated from cases of clinical mastitis in Ireland and characterise the association between genotype and expression of a range of virulence attributes.

Materials and Methods: A panel of clinical mastitis-associated *S. aureus* isolates ($n = 120$) was tested for their clonal diversity by Multi-Locus Sequence Typing (MLST). Virulence gene content of the isolates was determined by DNA microarray analysis using the Alere Identibac *S. aureus* array. The genome of 8 isolates was sequenced using an Illumina MiSeq with 300 bp paired-end reads. Antimicrobial susceptibility testing for Penicillin (6 $\mu\text{g}/10$ IU), ampicillin (10 μg), amoxicillin and clavulanic acid (20 $\mu\text{g} + 10$ μg), oxacillin (1 μg), tetracycline (30 μg), kanamycin (30 μg), neomycin (30 IU), ceftiofur (30 μg), enrofloxacin (5 μg), erythromycin (15 μg), clindamycin (2 μg) and cefalexin (30 μg) was carried out using the disk diffusion method according to CLSI guidelines. The ability of the isolates to form a biofilm was determined by the microtitre plate assay. The ability of the isolates to adhere to and invade bovine mammary epithelial cells in vitro was quantified 3 hours post-infection by flow cytometry while quantitative sampling by ELISA of the levels of IL-1 β , IL-6, IL-8 and TNF α at 12 hours post-infection was used to determine the in vitro host response to infection.

Results: In total, 15 different sequence types (STs) were identified, which grouped into 3 lineages CC97 ($n = 64$), CC151 ($n = 42$) and ST136 ($n = 14$). DNA microarray analysis and whole genome sequencing revealed a genomic rearrangement within isolates from CC97, with a sub-group related to ST71 showing evidence of an IS431 insertion element having replaced approximately 30 kb of DNA including the intercellular adhesin (*ica*) operon and the histidine biosynthesis genes. This resulted in histidine auxotrophy among the ST71-like isolates. As this sub-group differed from typical CC97 in a number of virulence genes, including the *ica* operon, collagen-binding protein (*cna*) and capsule type, they were treated as a separate lineage for analysis purposes resulting in four lineages, CC71 ($n = 42$), CC97 ($n = 22$), CC151 ($n = 42$) and ST136 ($n = 14$). Over half of the isolates (53%) demonstrated resistance to penicillin and ampicillin but all were susceptible to the other antibiotics tested. Penicillin and ampicillin resistance was associated with both CC71 and CC97. There were no differences among the lineages in ability to bind to or invade bovine mammary epithelial cells in vitro although there were significant differences between individual isolates. There was a significant difference between the lineages in ability to form a biofilm ($P < 0.0001$) with ST136 forming the strongest biofilm while CC151 formed the weakest biofilm. CC97 and CC71 also induced a significantly stronger IL-1 β and IL-6 host immune response from bovine mammary epithelial cells in vitro than CC151 or ST136 ($P < 0.01$).

Conclusions: The genotypes of *S. aureus* associated with clinical mastitis in Ireland were restricted to a small number of known bovine-adapted lineages. A genomic rearrangement within one of the lineages was discovered that may be responsible for diversification of this sub-group to an emerging bovine-adapted group. With the exception of penicillin and ampicillin resistance, resistance to other antimicrobials was not detected. The lineages differed in their ability to form a biofilm and their ability to induce a host immune response in vitro indicating the potential for a strain-specific immune response to infection.

Udder Health & Milk Quality

P01-001-205

Evaluation of the effect of clinical mastitis on udder firmness in lactating dairy cows

Anne Rees¹, Carola Fischer-Tenhagen¹, Wolfgang Heuwieser¹

¹Clinic for Animal Reproduction, Freie Universität Berlin, 14163 Berlin, Germany

Objectives: Detection of infected udder quarters precedes the recently intensively discussed antibiotic therapy of clinical mastitis (CM). Determination of udder firmness is a frequently applied method to diagnose CM. The increasing number of automatic milking systems where detection of CM is carried out automatically requires improved detection methods. We set out to (1) determine if udder firmness determined with a validated dynamometer can be used as a cow-side detection tool for CM and (2) to establish objective firmness thresholds for the differentiation between cows without and with CM.

Materials and Methods: The study was conducted on a commercial dairy farm milking 1,200 Holstein-Friesian dairy cows. Cows were milked 3 times a day. The annual milk yield was 10,140 kg. Cows with signs of CM (i.e., clots or flakes in foremilk samples) were separated into a mastitis pen. During the study period, average somatic cell count was 230,000 per ml bulk tank milk and incidence of CM was 24 cases per 100 cow-years.

Udder firmness of 95 healthy cows and 45 cows with CM in one of their hind quarters was measured by the same investigator before and after milking with a dynamometer (Penefel DFT 14; Agro Technologies, Forges-les-Eaux, France). The dynamometer was used according to standard operating procedures. Milk was sampled and cultured using standard microbiologic methods.

The time (before or after milking) and location within an udder quarter (upper, middle, lower measuring point) for diagnosing CM was tested. Further calculations were performed using the difference in udder firmness between both hind quarters of a given cow (Δ firmness) as the primary outcome. Influencing factors on Δ firmness were tested by generating a generalized mixed model with CM, milk yield per day, DIM, parity and gram staining characteristics of sampled bacteria as included factors. A receiver operating characteristic (ROC) curve was calculated to evaluate the performance of Δ firmness as a diagnostic tool for CM and provide thresholds for firmness values to differentiate between cows with and without CM.

Results: Median (and interquartile range (IQR)) udder firmness in quarters without (1.867 kg, 1.243 to 2.671 kg, $n = 6,340$) and with CM (1.948 kg, 1.213 kg to 2.819 kg, $n = 1,220$) was similar before milking ($P = 0.675$). After milking, udder firmness differed ($P < 0.001$) between quarters without (0.636 kg, 0.514 to 0.783 kg) and with CM (1.036 kg, 0.704 to 1.702 kg).

Firmness of both hind quarters within a cow without CM did not differ ($P = 0.369$) whereas firmness of both hind quarters within a cow with CM differed ($P < 0.001$).

Median (and IQR) firmness of the middle measuring point was 0.722 kg (0.600 to 0.864 kg) in quarters without CM and 1.297 kg (0.844 to 1.959 kg) in quarters with CM ($P < 0.001$). This middle measuring point was the firmest point in quarters without CM. In quarters with CM, there was no difference in firmness of the middle and the lower measuring point (1.203 kg, 0.771 to 2.053 kg, $P = 0.257$).

Median (and IQR) Δ firmness differed ($P < 0.001$) between cows without (0.098 kg, 0.030 to 0.216 kg) and with CM (0.756 kg, 0.170 to 1.914 kg). In cows in their 2nd and higher lactation, Δ firmness after milking was affected by CM ($P < 0.001$), milk yield per day ($P = 0.001$) and DIM ($P = 0.001$). Except for CM ($P < 0.001$), other tested factors did not affect Δ firmness after milking in cows in their 1st lactation. A threshold (area under the ROC curve) of 0.282 (0.722) and 0.425 kg (0.817) Δ firmness provided the best combination of sensitivity and specificity i.e., identified 64% of 1st lactating cows and 62% of older cows as truly suffering from CM, respectively.

Conclusions: The increased firmness of an udder quarter with CM does not affect firmness of its neighboring quarter. To diagnose CM, udders should be examined after milking using a defined measuring point located in the middle or lower part of a given quarter. Furthermore, different firmness thresholds for 1st lactating and older cows should be

used to reduce bias by parity. In conclusion, assessing udder firmness with the dynamometer can be a promising tool in daily udder health management.

P01-001-206

Prevalence and Risk Factors for Udder Cleft Dermatitis in Swedish Dairy Cows

Lisa Gustafsson^{1,2}, Ann Nyman², Elisabeth Bagge³, Ulf Magnusson¹, Karin Persson Waller^{1,2}

¹Department of clinical sciences, Swedish University of Agricultural Sciences, ²Department of animal health and antimicrobial strategies, ³Department of bacteriology, National Veterinary Institute, Uppsala, Sweden

Objectives: Udder cleft dermatitis (UCD) occur in the anterior parts of the udder of dairy cows. Cows with UCD may have increased risk of clinical mastitis, and associations between UCD and digital dermatitis (DD) have also been suggested. However, there are few large-scale studies investigating prevalence, etiology or risk factors. As the lesions are likely to have negative effects on animal welfare preventive measures are warranted. The objectives of the study were to investigate the prevalence of UCD in Swedish dairy herds, identify herd- and cow-level risk factors associated with UCD, and analyze associations between UCD and mastitis, DD and culling.

Materials and Methods: A random sample of 100 free-stall dairy herds with 50-210 cows, milking parlor and affiliation with the Swedish official milk recording scheme were included in the study. Each herd was visited once. Every second to third milking cow was examined and registered as having no UCD (no visual or palpable skin damages), mild UCD (small papules/pustulae, hyperkeratosis, small crusts and/or serum transudation) or severe UCD (large palpable skin damages, large crusts, pus, blood, deep skin wounds and/or proliferations). The cows were also examined for udder traits and the hygiene of the hind limb and udder was scored. Information on individual cows, herd management and cow environment factors was obtained on farm (via registrations and a questionnaire), and via the official milk recording scheme. Cow level risk factors included age, breed, days in milk, milk yield, udder conformation, hygiene, milk somatic cell count (SCC) and urea, hock lesions, claw disorders and reported diseases. Associations with mastitis cases 30 days before and after the visit, and culling up to three months after the visit were also analyzed. Herd level risk factors investigated were herd size, production system (organic or non-organic), average milk production, breed, bulk milk SCC and urea, stocking density, cubicle size, bedding material, routines for cleaning, milking (including use of water at milking), claw trimming and feeding, length of pasture period, problems with ectoparasites and registered veterinary treated diseases (with special regard to mastitis and DD).

Results: The total cow prevalence of UCD was 29% (1109 of 3775 cows). The majority (69%) of the UCD cases were mild while 31% of the cases were severe. The average herd prevalence of all UCD cases was 31% (range 0-64%), while the average herd prevalence of severe UCD was 10% (range 0-38%). The within-herd proportion of mild and severe cases varied markedly. Some herds had a high proportion of mild UCD with no or few severe cases. Other herds had similar proportions of mild and severe UCD, while a few herds mainly had severe cases. Only one herd had no cases of UCD. Associations between UCD and the risk factors are analyzed using univariable and

multivariable regression models and these results will be presented at the congress.

Conclusions: The fact that 10% of the cows suffered from severe UCD emphasizes the need for preventive measures. The UCD prevalence varied markedly between herds, as did the proportions of mild and severe UCD within herds, indicating that management or other herd factors may be important for the occurrence of UCD. Such factors, if identified, could be used to design preventive measures to reduce UCD prevalence. Longitudinal studies and microbial investigations of UCD lesions are needed to increase the understanding of why and how the lesions develop, persist and heal, and will also be performed within the project.

Understanding communication on mastitis management: could Motivational Interviewing aid in the uptake of advice?

Alison Scrase¹, David Main¹, Anne Haase², Helen R. Why¹, Emma Roe³, Kristen Reyher¹

¹School of Veterinary Sciences, ²School for Policy Studies, The University of Bristol, Bristol, ³Geography and Environment, University of Southampton, Southampton, United Kingdom

Objectives: Mastitis is one of the most significant causes of morbidity and mortality of the adult dairy cow (Ruegg 2011). Compliance with veterinary recommendations is critical to tackle incidence rates on farm (Green et al. 2007), yet improving uptake of advice in daily practice is a challenge (Jansen et al. 2010). Similar challenges are faced by the medical profession, who are increasingly employing an evidence-based communication methodology called Motivational Interviewing (MI) to improve public health. This research examines vet-farmer communication on disease, with the objective of establishing whether MI communication skills are currently in use.

Materials and Methods: Role play sessions reflecting consultations on lameness and mastitis were recorded between cattle veterinarians (n=15) recruited from two UK practices located in South West England and an actress experienced in role play in medical and veterinary education. The actress was provided with a character and farm profile reflecting a 'typical' UK situation, and veterinarians were provided with a short excerpt on the disease issue/risk factors on the farm and evidence to encourage them to broach a broad topic area of change with the farmer. Consultations lasted an average of 11.2 minutes (range 7.7 to 14.9).

Consultations were analysed using the MITI 4.2.1, a treatment integrity measure for clinical trials of MI. In this system, verbal interactions are firstly coded for frequencies of verbal behaviours: Giving Information, Persuading, Persuading with Permission, Questions, Reflections (simple/complex), Affirmations, Seeking Collaboration, Emphasising Autonomy and Confronting. Secondly, global scores are assigned on a five point Likert scale (from 1: low proficiency to 5: high proficiency) to characterise the entire consultation in relation to MI foci: Cultivating Change Talk, Softening Sustain Talk, Partnership and Empathy. To meet the level of 'basic competency' in MI, veterinarians required a mean score of 3.5 in Relational globals (Partnership, Empathy) and 3 in Technical globals (Cultivating Change Talk, Softening Sustain Talk), a Reflection to Question ratio of 1:1 and a 40% Complex Reflection percentage (of total Reflections). Coding was performed directly from audiotapes.

Results: MI communication skills were recorded within these veterinary consultations, yet no veterinarian was classified at a level of overall 'basic competency'.

Verbal behaviours

Veterinarians predominantly relied on Persuasion, Questions and Giving Information in their consultation approaches. Communication behaviours inadherent with MI (Persuasion and Confrontation, n=126) far exceed total MI adherent behaviours (Affirmations, Seeking Collaboration and Emphasising Autonomy, n=15), whilst no veterinarian achieved 'basic competency' with regards to Question: Reflection ratio (goal: 1:2). However, Reflections were found in nine of the fifteen veterinarian-farmer interactions.

Consultations approach: global scores

One veterinarian of the fifteen met the criteria for basic competence in MI with a mean score of 3.5 in Relational globals (Partnership, Empathy) and a mean score of 3 in Technical globals (Cultivating Change Talk, Softening Sustain Talk). However, mean global scores overall were low - Relational score = 1.6 (range 1-3.5) and Technical score = 1.7 (range 1-3).

Conclusions: These data suggest that current veterinary communication practices do not employ MI methods overall. However, some MI skill naturally occurs in practicing cattle veterinarians, indicating the feasibility of this methodology's utilisation within this context. Further training in this methodology could enhance the advisory process for both veterinarians and farmers, thereby improving the uptake of advice and reducing the incidence of mastitis, amongst other management challenges, on UK dairy farms.

Pathogens Agents of the Udder Isolated Milk Reception Boat of Goats with Mastitis the Municipality of Tanhuato Michoacan

Carlos Bedolla¹·Rodolfo Lucio¹·Victor Manuel Sánchez¹·Hugo Castañeda²·Valente Velázquez³·Edith García¹·José Carlos Bedolla⁴

¹Animal production, University Michoacana of San Nicholas of Hidalgo, Morelia, Michoacán, ²Bovine Mastitis Laboratory, University of Guadalajara, Guadalajara, Jalisco, ³Health Animal, University Autonomous of State of Mexico, Toluca, ⁴University Michoacana of San Nicholas of Hidalgo, Morelia, Michoacán, Mexico

Objectives: Identify the pathogens agents of the udder isolated milk reception boat of goats with mastitis the municipality of Tanhuato, Michoacán.

Identify the presence of *Staphylococcus aureus* as the main causative agent of mastitis in goats the municipality of Tanhuato, Michoacán.

Materials and Methods: The number of sample units (n = 49 stables) was calculated using a random model with proportional distribution function of the system characterization by small-scale dairy and major conglomerates. Sampling within herds was per cluster, ie a milk sample pot of receipt of each production unit was taken. the sampling of milk using for this test tubes sterilized sealing plug in which the necessary identification previously stable are scored. The test tube is placed inclined to keep out dirt. The sampling was made directly from the milk storage tanks. The sample tube was filled with two thirds at most. Finally, the sample tubes were placed on a rack placed in a sealed cooler for

further transport to the laboratory of bacteriology of USAD of the Faculty of Veterinary Medicine and Animal Husbandry for immediate processing or refrigeration at 4 ° C. The processing of the milk samples obtained was held on sampling or the next day. Samples were seeded in 110 staphylococcal agar, azide blood agar and Mc Conkey agar. Then, the agar plates were incubated at 37 ° C and examined after 24 and 48 hours. The isolates were identified by colonial morphology, Gram stain, catalase test, coagulase test and the test of mannitol and gelatin. A isolates Mc Conkey agar, they were made corresponding biochemical tests for identification. The tests used were: Urea, citrate, SIM (Sulfide Indole Motility) test, Agar triple-sugariron for its acronym in English TSI, Middle MRPV (methyl red Voges-Proskauer).

Results: 49 samples of the boat receiving equal number of dairy herds goats, of which a total of 61 bacterial strains (100%) were isolated were collected. Of these, 29 (47.54%) were Gram-positive pathogens, while 32 (52.46%) Gram-negative pathogens. On the results of bacteriological analysis of the milk samples obtained in this study (Table 1), the staphylococci were identified as the main etiologic agents Gram-positive mastitis, among which the *S. aureus* as the main causal agent 21 insulation, equivalent to 34.43%, as well as coagulase negatives which mainly found pathogen was *Staphylococcus epidermidis* with 8 isolates representing 13.11%, results appear to be similar to an investigation by Ferrer, et al (1993) who obtained 12 cases, equivalent to 11.5% of *Staphylococcus aureus* and 46 equivalent to 44% divided into agents coagulase negative cases.

Conclusions: It is concluded that *Staphylococcus aureus* was the main pathogen found in samples of milk pot receiving goats Tanhuato municipality, Michoacan, followed by *Proteus mirabilis*, coagulase Negative (*Staphylococcus epidermidis*) and agents Gram negative pathogens: *Citrobacter intermedium*, *Proteus rettgeri*, *liquefaciens serratia*, *Alcaligenes faecalis* and *Citrobacter freundii*.

An investigation of the incidence of milk leakage after dry-off in Commercial Dairy Herds around Europe

Ana De Prado¹·A Appiani²·A Velthuis³·L Bertocchi⁴·O Becvar⁵·J Davidek⁶·D Bay⁷·P Le Page⁸·M Holstege³·A Veenkamp⁸·T van Werven⁸·B Dalez⁸·J H Paduch⁸·K Kromker⁸·S Piepers⁸·Y Schukken³·L Jimenez⁸

¹Ceva Animal Health, Libourne, France, ²Milk Leakage Research Consortium, A, -, ³GD Animal Health, Deventer, Netherlands, ⁴Milk Leak Research Consortium, ⁵Milk Leakage Research Consortium, ⁶Milk Leakage Research Consortium, ⁷Milk Leakage Research Consortium, ⁸Milk Leakage Research Consortium, ⁹Milk Leakage Research Consortium, A,

Objectives: The objective of the study was to investigate the incidence of cows leaking milk during the first two days post dry-off on commercial dairy farms around Europe and to investigate the relationship between milk leakage and milk production.

Materials and Methods: This study was carried out in commercial dairy farms in France, Germany, Italy, The Netherlands, Belgium, Spain, Czech Republic and Denmark. A total of 1,142 cows from 41 farms were included in the study. All cows had a satisfactory general health based on a physical examination including clinical mastitis, four functional quarters and were not treated with internal or external teat seal. Milk leakage was observed at three visits (V): between 20 to 24 hours (V1), 30 to 34 hours (V2) and 48 to 52 hours (V3) after the dry-off. Cows had

to stand in headlocks and were observed twice per visit for 30 seconds each. Milk leakage was considered to be present when a stream of milk was coming from a teat, when a milk drop on the teat was present or when milk was present on the ground under the udder. Milk production data during the last 24 hours before dry-off was obtained from the records on the milking system. The individual cow was the experimental unit, whereas the quarter was the data collection unit. Generalized linear models with random effects for farm were used to test the relation between milk leakage and production.

Results: Milk leakage within two days after dry-off was observed in 279 out of the 1142 cows, resulting in a mean milk leakage incidence per farm of 24.4% (95% CI: 21.9% - 26.9%). Cows with observed milk leakage, had on average 1.6 leaking teats (95% CI: 1.56 - 1.66). In 55.3% of the cows leaking milk one quarter was leaking, in 32.3% two quarters, in 8.3% three quarters and in 4.1% four quarters. Rear quarters turned out to have 4.3 times as many odds on milk leakage than front quarters (95% CI: 3.3 - 5.7). Most milk leakage (on average 30,1% of the cows per farm) was observed between 30 and 34 hours after dry-off compared to on average 14,7% of the cows per farm between 20 to 24 hours and 17,2% between 48 to 52 hours, respectively. The last recorded yield 24h before dry-off was significantly associated with milk leaking. Cows with a higher last recorded yield had 2.6 (95% CI: 1.61 - 4.27) higher odds on milk leakage than cows with a lower last recorded yield, even though the association was not completely linear.

Conclusions: Results show that the incidence of milk leakage in these European dairy farms is 24.4% average. Due to the link between the cow milk production the last day before dry-off and the incidence of milk leakage after dry-off, the data indicate that higher milk production at dry-off is a predictor of milk leaking after dry off.

Effect of a single injection of Cabergoline (Velactis®) on the incidence of milk leakage after dry-off in large dairy herds in Mexico

Ana De Prado ¹G Mapes ²C Martinez ³K Solis-Rodriguez ⁴A Lopez ⁵

¹Ceva Animal Health, Libourne, France, ²Ceva Animal Health, Libourne, ³Ceva Salud Animal, ⁴Independent Veterinary, Mexico City, Mexico, ⁵Ceva Sante Animale, Libourne, France

Objectives: The objective of the study was to investigate the efficacy of one injection of Cabergoline (Velactis®, Ceva Sante Animale) at the moment of dry-off on the percentage of cows leaking milk during the first two days after the dry-off in large dairy herds in Mexico. The relationship between milk leakage and milk production was also investigated.

Materials and Methods: This multi-site, randomized and blinded study was carried out in two large commercial dairy cows in Mexico. A total of 1,072 cows from 2 farms were enrolled in the study. The involved cows for the study had a satisfactory general health based on a physical examination including clinical mastitis, four functional quarters and were not treated with internal or external teat seal. The cows were randomized to receive 2 treatments to evaluate the incidence of milk leakage. After the last milking 535 cows received a single i.m. injection of 5 mL of a solution containing 5.6 mg of cabergoline (Velactis®-VEL-) and 537 received an equivalent volume of placebo (only excipient -PLA). Milk leakage was observed at three visits: between 16 to 20 hours, 24 to 28 hours and 42 to 46 hours after the dry-off. For this, cows had to stand in headlocks and were observed twice per visit for 30 seconds each.

Milk leakage was considered to be present when a stream of milk was coming from a teat, when a milk drop on the teat was present or when milk was present on the ground under the udder. Milk production data during the last 24 hours before dry-off was obtained from the records. The individual cow was the experimental unit, whereas the quarter was the data collection unit. The statistical unit was the cow. Student t-Test was used to compare milk production between groups and Chi - test was used for binomial comparisons between groups.

Results: Average milk production at dry-off did not differ (p=0.79) between treatment groups, and it was 17.7 ± 10.6 and 17.5 ± 10.3 for cows on PLA or VEL respectively. After the dry-off, milk leakage was observed in 29.2% (95% CI: 25.4% - 33.2%) PLA (157 out of 537) and 10.8% (95% CI: 8.3% - 13.8%) VEL (58 out of 535) respectively (p

Conclusions: Data show that the treatment with a single i.m. Injection of 5 mL of a solution containing 5.6 mg of cabergoline (VEL; Velactis®, Ceva Sante Animale) results in a relative risk reduction of 63% in milk leakage on the two first days after dry-off compared with placebo group.

An investigation to determine visual presence of milk leakage in US commercial dairy farms after dry-off

Ana De Prado ¹M Colgin ²P Busman ³K Mitchell ⁴M Capel ⁵

¹Ceva Sante Animale, Libourne, France, ²Ceva Animal Health, Lenexa KS, ³Sparta Animal Clinic, Sparta, MI, ⁴Valley Veterinarians, Tulare CA, ⁵Perry Veterinary Clinic, Perry NY, United States

Objectives: The objective of this study was to determine the visual presence of milk leakage on commercial U.S. farms at 4 hours, 8 hours, 12 hours, 24 hours, 36 hours and 48 hours after the last milking at drying off in dairy cows.

Materials and Methods: This was a multi-site survey to determine the presence of milk leakage after the last milking at dry-off. The animal phase of the study was conducted at three commercial dairies in California, Michigan and New York. A total of 312 Holstein cows were included in the study. Cows were observed in weekly cohorts according to the dairy's current dry-off schedule. Each site enrolled approximately 100 animals (Site A- 100; Site B- 108; Site C- 104) where each cohort included no more than 35% first calf heifers. All cows had a satisfactory general health based on a physical examination including evaluation for clinical mastitis, and had not been treated with internal or external teat seal. Cows with more than one non-functioning quarter were excluded from the study. Cows were observed and milk leakage was assessed after the last milking at dry off at the following time points: 4 hours, 8 hours, 12 hours, 24 hours, 36 hours, and 48 hours. The milk leakage visual observation was made without any manipulation of the teats. A cow was positive for milk leakage if dripping or squirting of milk was observed from one or more teats directly within the lock-up, stanchion or freestall. Milk leakage was observed and evaluated statistically on a cow basis.

Results: Milk leakage within 2 days after dry off was observed in 81 out of 312 cows, resulting in a mean milk leakage incidence per farm of 26%. The site-specific incidence varied from 19% to 35% during the full observation period of 48 hours. The observation of leakage was related to observation interval, with a higher incidence rate of leakage at the later 24 hour (13.7%), 36 hour (21.1%) and 48 hour (14%) observation intervals.

Conclusions: Results show that the incidence of milk leakage in these USA commercial dairy farms is 26% average. Researchers have been identified milk leakage as a major risk factor for the acquisition of new intramammary infections during the dry off period. Strategies to reduce milk leakage should be considered to improve udder health.

Survivability of *Mycoplasma* spp. Isolated from milk samples from South Australia in different storage conditions

Abd Al-Bar Al-Farha¹, Farhid Hemmatzadeh¹, Darren Trott², Andrew Hoare³, Kiro Petrovski²

¹School of Animal and Veterinary Sciences, ²The University of Adelaide, Roseworthy, ³South East Vets, Mt Gambier, Australia

Objectives: The study aims to evaluate the recovery of *Mycoplasma* spp. isolated from milk samples under different storage conditions. This study should provide veterinarians and farmers in designing appropriate procedures to keep milk samples in order to use them for *Mycoplasma* detection. Furthermore, the study will compare between some cryoprotectants to avoid the intra and extracellular freezing injuries of *Mycoplasma* spp.

Materials and Methods: Four different regimens of storage conditions were used to compare the recoverability of *Mycoplasma* spp isolates after various periods of time. Samples were collected from a single dairy farm in Mount Gambier, South Australia. According to the culture and PCR tests, thirty of *Mycoplasma* positive milk samples have been selected for storage-recovery test. Each of these samples was aliquoted into twelve (0.5 mL) Eppendorf tubes for each experiment. The first experiment was carried out using 40% of glycerol, 10% Dimethyl Sulphoxide (DMSO) and 50% (v-v) of 10 days *Mycoplasma*-culture broth. Similarly, Foetal Bovine Serum (FBS) was used in the second experiment instead of glycerol with 40% concentration in addition to 10% DMSO and 50% of the *Mycoplasma*-positive culture. Samples from the first and second experiments were stored in -80°C freezer. Freezing of the milk samples at -20°C was used as the third method, while the last storage method was using a 4°C fridge. After thawing at ambient temperature, 250 µL of each aliquot were cultured after 1, 2, 4 and 8 weeks interval to record the growth on agar plate (Oxoid Ltd.). Colony forming unit (CFU) was calculated for each sample regimens and compared with the initial culture results using kappa agreement procedure in SAS.

Results: Results have shown a variety of *Mycoplasma* recoverability using the four different storage techniques for different times. *Mycoplasma* survived well in Glycerol and DMSO with 100% recovery rate for the duration of the experimental period. The combination of FBS and DMSO has shown lesser survival with 90%, 70%, 60% and 30% for week 1, 2, 4 and 8 respectively at -80°C. The recovery rate declined under -20°C storage with 80%, 75%, 66% and 30% for week 1, 2, 4 and 8 respectively. The lowest survivability was observed with the fridge milk samples with 50%, 30%, 10% and 0%, respectively.

PARTS OF THE RESULTS ARE STILL EXPECTED. THEY WILL BE AVIALBLE BY THE END OF FEBRUARY 2016. THEREFORE, SOME OF THE VALUES ABOVE MAY CHANGE.

Conclusions: Unless using fresh milk samples, a combination of Glycerol and DMSO has been found as appropriate cryoprotectants for *Mycoplasma* storage. Results of this study may contribute to overcome

the survival challenges of *Mycoplasmas* due to their fastidiousness. Additionally, this methodology can be used for long distance transport of microbiological milk samples. For farmers and veterinarians, storage of milk samples in -20°C appears to be more efficient than fridge.

Bacteriological etiology of mastitis in Finland in different housing and milking systems

Johanna Vakkamäki¹, Suvu Taponen¹, Anna-Maija Heikkilä², Eero Liski², Satu Pyörälä¹

¹Department of Production Animal Medicine, University of Helsinki, ²Economics and Society, Natural Resources Institute Finland, Helsinki, Finland

Objectives: Knowledge on the bacteriological etiology of mastitis is important for efficient mastitis control and treatment. In Finland, milk samples for bacteriology are taken in most cases of mastitis. Since the year 2010, samples have been analyzed using a quantitative PCR test (PathoProof™ Mastitis PCR Assay, Thermo Fisher Scientific, Finland). The test targets DNA of 15 bacterial species or groups of species. The aim of this study was to define the distribution of pathogens identified by the PCR test in different housing and milking systems.

Materials and Methods: The data consisted of 243,520 aseptic quarter milk samples sent to Valio Laboratory during 2010-2012. The samples originated mainly from subclinical or mild clinical mastitis and were mostly taken by herd staff. The milk samples were taken from 93,530 individual dairy cows on 4,725 dairy farms. Milk samples with DNA of one target only were included in the study. The data containing records of analyzed milk samples were merged with the data from the Finnish dairy herd recording system. In addition to production data, this system includes information on herd and cow factors like housing and milking type.

Results: Both housing and milking system were associated with proportions of different bacteria in milk samples. Coagulase-negative staphylococci (CNS) were the most frequent bacteria found in milk samples. The proportion of CNS in milk samples was bigger in tie stall (45%) compared to cold (38%) or warm (42%) free stall housing, and in automatic milking compared to parlour milking. The proportion of *Staphylococcus* (*S.*) *aureus* in milk samples was bigger in tie stall (24%) and warm free stall (19%) housing compared to cold free stall (14%) housing, and in parlour milking (19%) compared to automatic milking (16%). The proportion on *Streptococcus* (*Str.*) *uberis* in milk samples was bigger in cold free stall (12%) housing compared to warm free stall (9%) or tie stall (9%) housing. On the contrary, the proportion of *Str. dysgalactiae* in milk samples was bigger in warm free stall (9%) compared to cold free stall (6%) and tie stall (7%) housing. The proportion of *Corynebacterium* (*C.*) *bovis* was bigger in cold free-stall (14%) compared to warm free-stall (7%) and tie stall (6%) housing. The proportion of *Escherichia* (*E.*) *coli* in milk samples was bigger in free-stall (cold 7%, warm 6%) than in tie stall (3%) housing. *Str. agalactiae* was an infrequent finding which was associated more commonly with automatic milking (1.5%) than with parlour (0.3%) or tie stall (0.1%) milking.

Conclusions: Both housing (tie stall, cold and warm free stall) and milking system (pipe line in tie stall, parlour and automatic milking) were found to be associated with the proportions of different mastitis causing bacteria in milk samples sent for bacteriological analysis. Housing and milking systems are not independent as certain type of milking

systems are used in certain types of housing systems. Thus, the real causes behind these associations may be the housing and management conditions in barns of different age and size.

Comparison of different methods to assess the quality of bovine colostrum

Franz Kritzingner¹, Carola Sauter-Louis², Rolf Mansfeld³

¹Veterinary, Vöcklamarkt, Austria, ²Institute for Epidemiology, Friedrich-Loeffler-Institut, Greifswald - Insel Riems, ³Clinic for Ruminants with Ambulatory and Herd Health Services, LMU Munich, Oberschleissheim, Germany

Objectives: It is vital for new-born calves to obtain good quality colostrum. The main method to assess the quality of colostrum is determining the concentration of immunoglobulin G. Several methods are available to assess this concentration: either in the laboratory, using a colostrometer, or using digital or optical refractometers. The present study had the objective to compare different methods for assessing the quality of bovine colostrum, including a newly developed method of using a standardised funnel.

Materials and Methods: Two different refractometers (optical and digital), one colostrometer and a funnel, as used in the varnish industry were used to assess the colostrum of 124 cows. In addition the lactation of the cow, the time between calving and milking (in hours) and the time between milking and measuring (in minutes) were recorded. After the milking the quality of the colostrum was assessed using an optical and a digital refractometer. Thereafter, the colostrum was frozen and later on thawed again for the examination using the refractometers again, using a colostrometer, using the funnel, determining the density and the IgG-concentration.

Results: Using the concentration of IgG as a gold-standard the different methods reached correlations between 0.42 up to 0.64. Correlations between the refractometers and the colostrometer were higher (up to $r=0.86$). Factors influencing the IgG-concentration were the time period between calving and milking and the lactation of the cow. Freezing and thawing of the colostrum did not have any effect on the measurements.

Although the correlations between the time measured in the funnel and the IgG-concentration was the lowest ($r = 0.42$), the method showed a good discrimination between two classes of colostrum (less than or greater than 50 mg/ml) with an area under the curve in a ROC-analysis of 0.864. Parameters like lactation period and time between calving and first milking were used to evaluate their effect on the times measured in the funnel.

Conclusions: In conclusion, there are several methods available for assessing the quality of bovine colostrum. A newly developed method of using a standardised funnel provides an easy to use technique to validly assess the quality of cows' colostrum.

Udder Health & Milk Quality

P01-001-216

Clinical and economic comparison of immediate blanket treatment versus pathogen based treatment for clinical mastitis in a New York dairy herd

Michael B. Capel¹, Daryl V. Nydam², Amy K. Vasquez², Paul D. Virkler², Steve Eicker³

¹Perry Veterinary Clinic, Geneseo, ²Department of Population Medicine and Diagnostic Sciences, College of Veterinary Medicine, Cornell University, Ithaca, ³Valley Agricultural Software, King Ferry, United States

Objectives: Current practice on many dairies is the immediate treatment of all clinical mastitis (CM) cases with intramammary (IMM) antibiotics or "blanket therapy." Pathogen based mastitis therapy has the potential for targeted use of IMM antibiotics, avoiding their overuse, reducing treatment costs, and increasing saleable milk. The objective of this study was to compare the clinical and economic impacts of blanket IMM therapy with a pathogen based approach. Survival and production indices were used and a partial budget analysis was performed to compare differences in the two approaches using measured outcomes from an on-farm clinical trial.

Materials and Methods: Clinical mastitis (CM) cases at a 3500 cow dairy in New York State Dec 2014-Apr 2015 were included. Cows with systemic signs, prior antimicrobial treatment (<15d), or impending sale were excluded. Cows with CM were randomly assigned to the blanket (BT) or pathogen based (PB) therapy group. Mastitic milk samples were collected daily. Pathogen results were available after 24h by direct upload onto farm computers. Cultures were performed according to NMC guidelines at Quality Milk Production Services. Cows in the BT group received 1 tube of ceftiofur hydrochloride into the affected quarter for 5d. Cows in the PB group received no treatment for the first 24h. Upon upload of results, the following protocol was automatically assigned via Dairy Comp 305: Staph spp., Strep spp., or Enterococcus positive cows were administered 1 IMM tube of cephapirin sodium every 12h for two treatments. Cows positive for other organisms or no growth received no treatment. Cows in either group positive for Prototheca, Mycoplasma, S. aureus, or Strep ag. were culled. Outcomes included days to return to normal milk, days out of the tank, linear score and milk production 8-43d post treatment, removal from the herd <30d or <60d post CM. Analysis was performed using multivariable models in SAS[®] 9.4. Costs were as follows: \$3.80/tube of ceftiofur, \$3.10/tube of cephapirin, labor=\$15/hr, \$6.00/culture. Milk discard value was based on 27kg/d production for mastitis cows and a \$20/100 pounds of milk price. Herd level costs were based on 5% monthly incidence of CM per 100 lactating cows.

Results: A total of 725 cases of CM were included; 114 cows were excluded due to systemic illness (16%). Distribution of treatments for the 489 included CM events was equal between groups. The proportion of CM cases assigned to the BT and PB that received IMM therapy was 100% and 32.1%, respectively. No statistically significant differences existed between BT and PB therapy in days to clinical cure (means: PB=4.5, BT=4.8). The difference in post-CM milk production between groups was not significant (means: PB = 34.7 kg, BT = 35.3 kg). No significant differences were observed in test day linear scores (LS) between groups (least squares means (LSM) of LS = 4.3 for PB cows and 4.2 for BT cows. Risk of survival 30 d post-enrollment was the same for both groups (Odds Ratio of PB as reference=1.57, 95% CI: 0.66-3.74) as was risk of survival to 60 d (OR=1.39, 95% CI: 0.75-2.57). However, PB cows experienced an average of 3 d fewer out of the tank. Costs associated with clinical mastitis treatment group were as follows:

Direct Cost per Treatment Protocol: BT \$132.05 / PB IMM therapy \$99.95, no IMM therapy \$67.25;

Total Direct Cost by Treatment Group: BT \$132.05 / PB \$78.24 (difference of \$53.81 per case)

Cost of Mastitis Treatment / 100 Cows: BT \$7,923 / CBT \$4,694; Savings per 100 Cows: \$3,229

Conclusions: Almost 70% of moderate and mild CM cases would not have been treated if all CM trial cows were enrolled in a pathogen based protocol. This strategic method of treatment decreased average days out of the tank by 3d for those cows on the pathogen based protocol, with no difference in days to clinical cure, milk yields, and LS post-mastitis event; nor additional risk of culling in the days following. The use of pathogen based therapy to guide the treatment of clinical mastitis reduced treatment costs, increased the volume of saleable milk, and increased cash flow over \$3,000 per 100 cow milking cows with no negative impact on clinical outcomes.

P01-001-217

Mycoplasma bovis infection and shedding in naturally infected dairy cows

Antonio Barberio ¹; Brunella Dall'Ava ¹; Giulia Rosa ¹; Alice Fincato ²; Federica Gobbo ^{2,3}; Alessio Bortolami ^{4,5}; Salvatore Catania ²

¹Sezione Territoriale di Vicenza, Istituto Zooprofilattico Sperimentale delle Venezie, Vicenza, ²Laboratorio di Medicina Aviare, Istituto Zooprofilattico Sperimentale delle Venezie, ³Dipartimento di Medicina Animale Produzioni e Salute, Università di Padova, ⁴Sezione Territoriale di Padova, Istituto Zooprofilattico Sperimentale delle Venezie, Legnaro, Italy, ⁵Diagnostic Microbiology Trainee, University of Liverpool, Liverpool, United Kingdom

Objectives: *Mycoplasma bovis* mastitis has been considered contagious in nature and is transmitted from infected to uninfected udders mostly at milking time. Still, the transmission may less commonly occurs from other source than mammary gland, like the mucosal of nasal cavities, eye and vagina. For these reasons an evaluation of the shedding pathways of *M. bovis* in infected cows could be useful to better understand the transmission of this microorganism in dairy herd. Thus the aim of this study was to describe the shedding of *M. bovis* in a group of naturally infected dairy cows.

Materials and Methods: The study was realized in a dairy farm located in the north-east of Italy: the herd size was 240 cows, milked in a herringbone parlour and housed in freestall barns. Due to the finding of *M. bovis* infection in 2 cows with subclinical mastitis, the milk of each cow was tested for the detection of the pathogen, so others 15 infected cows were found. The farmer decided to cull immediately only 3 infected cows and to postpone the culling of the others 14 cows. These 14 naturally infected cows were sampled monthly for 5 months: milk from each single quarter and nasal and vaginal swabs were collected. A single nasal swab was taken from each nostril, and another swab was taken from vaginal mucosa. Immediately after sampling the swabs were dipped in 2 mL of Mycoplasma Experience (ME) broth medium (ME LTD, Reigate, UK). Milk was collected aseptically in 10 ml tubes and submitted to the following test: standard culture (according to the National Mastitis Council procedure), somatic cells count (SCC) by mean of DeLaval cell counter (DeLaval A.B., Tumba, Sweden) and *M. bovis* culture. For *M. bovis* isolation the samples were inoculated onto ME broth medium (ME LTD, Reigate, UK) and incubated at 37±1 °C under 5% CO₂. Broths were checked daily for the presence of turbidity/changing colour, then they were plated on ME agar medium (ME LTD, Reigate, UK), and

checked for the presence of *M. bovis* colonies. In order to confirm the identification of *M. bovis*, DNA was extracted from suspect samples and a 16S-rDNA PCR and Denaturing Gradient Gel Electrophoresis (DGGE) method were performed.

Results: At the 1st control 31 quarters (55%) were found infected with *M. bovis* and 10 cows (71%) had 2 or more infected quarters. Among infected quarters, 13 (23%) had a SCC > 200.000 cells/mL. At the 2nd control 12 cows were sampled (2 were dried-off). Among these, 25 quarters (52%) were found positive and 17 (35%) had a SCC > 200.000 cells/mL. Only 10 cows were positive to *M. bovis* and 8 cows (67%) had 2 or more infected quarters. Of the 2 negative cows 1 had at the previous control only 1 infected quarter, and the other 2. At the 3rd control were tested 10 cows (1 was dried-off and 1 culled), and 8 were still infected. The numbers of quarters found positive to *M. bovis* was 19 (48%), and 12 (30%) had a SCC > 200.000 cells/mL. Among the 8 infected cows, 7 had 2 or more infected quarters. At the 4th control only 8 cows were sampled due the culling of the others: among them 3 cows tested negative: 1 was negative also at the 2nd and 3rd test, 1 was at the first control after the dry-off and 1 had tested positive to the previous tests in only 1 quarter. The number of infected quarters was 9 (28%), 7 (22%) had a SCC > 200.000 cells/mL, and 4 cows (50%) had 2 or more infected quarters. At the 5th control among 8 cows 4 were still infected. The number of infected quarters was 5 (16%), and 4 (13%) had a SCC > 200.000 cells/mL. All the vaginal and nose swabs collected were negative for the presence of *M. bovis*. During the study, the presence of clinical symptoms were observed only in 4 quarters: agalactia in 3 quarters and the presence of flaky sediments in the milk in 1 quarter.

Conclusions: The majority of the cows involved in this study were affected only by a *M. bovis* subclinical mastitis. The SCC of infected quarters fluctuated during the time of the study also below 200.000 cells/ml, and some quarters recovered from the infection. These findings suggest that *M. bovis* infection can induce in the mammary gland a self-limiting disease that could be more difficult to recognize, compared to the classical form of mastitis. The *M. bovis* shedding in these cows occurred only in the milk, demonstrating that only the mammary gland has been colonized by the microorganism.

Comparison of bacteriological finding in milk samples analyzed by 3 different laboratories

Sandra Bertulat ¹; Rona Müller ¹; Wolfgang Heuwieser ¹

¹Clinic for Animal Reproduction, Freie Universität Berlin, Berlin, Germany

Objectives: The routine diagnostic of mastitis pathogens and antimicrobial resistances mostly includes the bacteriological examination. This gold standard, however, has several limitations. Sterile milk samples are necessary to achieve reliable results and transport between farm and laboratory, often conducted without cooling, might bias the results. An inter-laboratory comparison of Finnish milk laboratories has been published in 2005, however, only spiked milk samples were used in this study. Therefore, the objective of our study was to compare bacteriological results of milk samples collected in the field and shipped to 3 different laboratories.

Materials and Methods: A total of 792 milk samples (175 clinical and 250 subclinical mastitis, 346 healthy) were collected from July 2013 to June 2014 on a commercial dairy farm in Germany. Sterile milk samples were collected according to the guidelines from the International Dairy Federation. Samples were immediately cooled and transported to the laboratory of the Clinic for Animal Reproduction. Upon arrival all samples were vortexed for 15 sec, divided into 3 aliquots and filled into tubes coated with boric acid under sterile conditions. Each tube was sent to 1 of 3 different accredited milk laboratories (Lab A, B, C) that offer routine milk diagnostic for commercial dairy farms and veterinarians. Samples were sent by regular mail without cooling in order to provide influences similar to those samples are exposed to under normal circumstances. All samples arrived within 2d.

Samples in all labs were inoculated on agar plates and incubated. Isolated bacteria were identified based on colony and cell morphology, gram staining, hemolytic pattern, catalase activity and growth on differential and selective media. All samples were examined for the presence of bacteria, yeast and prototheca species and milk somatic cell count was evaluated. Furthermore, antimicrobial susceptibilities for 20 antimicrobials used in mastitis therapy were tested in 102 out of 792 samples.

Association and agreement between labs was estimated utilizing Chi-Square test or Fisher's Exact test, Cohens Kappa test, Spearman's (i.e., antimicrobial susceptibility) and Pearson's (i.e., SCC) Correlation Coefficient and paired t-test.

Results: In 42.3% of all samples the same bacteriological result (i.e., same pathogen or "no growth") was found by all three labs. The same pathogen genus (e.g., Streptococci) was diagnosed in 45.1% of the samples. Comparing only 2 out of 3 labs, Lab A and B identified the same pathogen in 57.4% of all samples (Kappa = 0.335; P < 0.001), the differentiation between gram positive and negative was identical in 95.4% of the results. Lab B and C had an agreement of 50.0% (Kappa = 0.308; P < 0.001) and 88.7% considering pathogen identification and gram stain, respectively. Best results were achieved between Lab A and C with 72.2% agreement between pathogen identification (Kappa = 0.561; P < 0.001) and 100% for gram stain. 17.8% of the results were gram negative. Agreement considering the decision "pathogen" or "no growth" was 62.6%, 63.6% and 74.4% between Lab A and B, B and C and A and C, respectively. Identical results by all labs were 50% no growth, 35.1% Staph. aureus, 6.8% Strep. uberis, 4.1% CNS, 2.7% Coliforms, 1.4% Strep. dysgalactiae.

Identical results considering antimicrobial susceptibility (i.e., susceptible, intermediate, resistant) were provided by all labs for 57.1% of the tested antimicrobials. Lab A and B provided the same results for 67.6% (Kappa = 0.322; R = 0.432; P < 0.001), Lab B and C for 61.1% (Kappa = 0.257; R = 0.341; P < 0.05) and Lab A and C for 71.0% (Kappa = 0.308; R = 0.391; P < 0.001) of the antimicrobials, respectively.

While somatic cell count results differed between labs as well (P < 0.02), the correlation was good (i.e., R = 0.854 - 0.959; P < 0.001).

Conclusions: Our study showed a fair to moderate agreement between laboratories considering pathogen identification, antimicrobial susceptibility and SCC. While our results slightly differ from previous comparisons utilizing spiked milk samples, they implicate that the bacteriological examination of milk samples might have limitations, e.g. if samples are sent by regular mail or without cooling. Considering current discussions on bacterial resistances and antimicrobial residues, further research is warranted to identify confounders that affect bacteriological results and to improve the reliability of results acquired by bacteriological examination.

P01-001-219

Validity of the Delvo Test SPNT® for Detection of Residues of Novel Antimicrobial Substances in Milk

Kiro Petrovski ¹ Neena Simon ¹ Hiu San Wong ¹ Stephen Page ² Darren Trott ¹

¹The University of Adelaide, Roseworthy, ²Luoda Phrama, Sydney, Australia

Objectives: The objectives of this study were to validate the Delvo test SPNT® for detection of residues of polyether ionophores in milk. The use of the Delvo test SPNT® is in detection of factors inhibiting the growth of the Bacillus stearothermophilus var calidolactis in the milk. Almost 80% of antibiotic residues in milk can be traced back to mastitis treatment. Systemic and oral treatment may also result in violative residues in milk. As some of the polyether ionophores are used orally, the potential of excretion in milk is present. Additionally, currently these antimicrobials are assessed for their potential use in mastitis treatment.

Materials and Methods: Four polyether ionophores (lasalocid, monensin, narasin and salinomycin) were used as test antimicrobials. Two beta-lactam antimicrobials (amoxicillin and cloxacillin) were used as positive controls. Non-spiked milk was used as negative control. The study was carried out in few steps, preparation of stock solution of the antimicrobials, spiking milk with known concentrations of the antimicrobials of interest and test operation.

Milk used in this study was collected from four individual cows known not to have been treated or fed with antimicrobials at least two weeks prior to the milk collection. A 0.75L portion per cow was comingled (commingled milk).

Stock solutions were prepared following the Clinical and Laboratory Standards Institute guidelines.

The spiked milk samples were prepared daily. Fixed volume (1µL) aliquot of the appropriate working solution at different antimicrobial concentrations was added to 99 µL of milk.

Operation of the Delvo test SP-NT® test was carried out following the manufacturer's recommendations. The end point colour change of all the test was assessed and recorded by a visual colour score from DSM food specialists®. Following the incubation period the colour change observed in the test bed was classified as one of the following categories: 100% yellow, 75% yellow, 50% purple, 75% Purple or 100% purple. A classification of 50% purple or greater was recorded as a positive test result. If discrepancy of more than one category occurred the testing for the appropriate antimicrobial concentration was repeated (n=2 occasions amoxicillin).

Results: No difference between the results obtained in full cream and skim milk sample was detected. Additionally, there was no difference in the results obtained from milk samples from individual cow or comingled milk. No false-negative or false-positive reactions were observed above or below the limit of detection (LOD) for any of the tested antimicrobials.

The Delvo test SP-NT® test was able to detect all four polyether ionophore compounds in milk in relatively low concentrations. The LOD for monensin was 0.25 µg/mL, for salinomycin 0.50 µg/mL, and for lasalocid and narasin was 1.00 µg/mL. Unfortunately, the LOD was 100-folds higher than the only registered MRL in Australia for the lasalocid.

The LOD for amoxicillin 0.003 µg/mL and for cloxacillin was 0.03 µg/mL. The LODs were within the industry standards for the Delvo test SP-NT® test. The LOD for amoxicillin was 3.3 times higher and for the cloxacillin 3 times below the Australian MRLs.

The DMSO was used to dilute the lipophilic and immiscible in water polyether ionophores. Milk was used as media for testing. The DMSO has been shown to have some antimicrobial activity against some microorganisms on its own. The regular monitoring programmes using microbial inhibition tests has also shown that milks from some cows and especially in early lactation of just before an episode of clinical mastitis may hold some unidentified inhibitory substances. Therefore, the DMSO and milk alone and in combination were used as control wells. Fortunately, no test with the DMSO and milk alone or in combination was positive.

Conclusions: The results from this study indicate that the Delvo test SPNT® is capable of detecting all four tested polyether antimicrobials. Unfortunately, the LOD was significantly higher than the registered MRL in Australia.

Ideally, the screening test should detect the potential antimicrobial residues of concern at or below the relevant MRL. Additionally, to protect the consumer, the test should produce minimal proportion of few false-negative results and to protect the producer, national and international trade, minimal proportion of false-positive results. The test performance regarding the false-positive and false-negative results was satisfactory.

P01-001-220

Characterization of fatty acids in bulk tank milk of dairy herds from Valle Camonica, a mountain zone in Lombardy Region, Italy

Giorgio Zanardi ¹; Silvia Bettoni ¹; Cristina Baiguera ¹; Antonio Marcolini ¹; Giuseppe Bolzoni ¹

¹Primary Livestock Production, Istituto Zooprofilattico Sperimentale della Lombardia e dell'Emilia Romagna, Brescia, Italy

Objectives: Aim of this survey has been to characterize and evaluate saturated (SAT), unsaturated (UNSAT), monounsaturated (MONO), polyunsaturated (POLY) fatty acids by Fourier Transform Infrared spectroscopy (FTIR) of the bulk tank milk collected from a representative sample of dairy herds located in a mountain area in province of Brescia, Lombardy region. The average fatty acid milk composition of 37 grazing dairy herds selected was compared with the detected one of 54 dairy herds feeding with uni-feed in flat lands.

Materials and Methods: Thirty seven dairy herds for 492 lactating cows, mainly Brown Alpine and Red Piebald, were selected on their feeding based mainly on hay, supplementary feed, without silage maize (October-May) and on the grazing in summer period (June-September). These were small size herds (average 12 heads) producing cheeses for self-consumption and/or direct sale. A questionnaire was realized and filled in order to determine the main features of the farms, particularly the feeding composition. Three alpine pastures were visited and followed up during summer mountain grazing. From April to August 2015 refrigerated bulk tank milk samples (BTMS) from all the selected herds were tested before (April-May) and during (June-July) the grazing season twice a month, for a total of 189 samples. Fat, protein, lactose, casein were analyzed by FTIR spectrometry MilkoscanFT6000® (Foss, DK) with management software Foss Integrator®. Calibration curves developed by producer for SAT, UNSAT, MONO, POLY fatty acids were recalibrated and validated with gas chromatography by our laboratory using milk samples from regional herds. Data were processed by univariate analysis using IBM SPSS STATISTICS 22.0.

Results: The mean values for fat, protein and casein detected on 37 dairy herds were, respectively, 4.15 g/mL (SD 0.602), 3.37 g/mL (SD 0.229), 2.64 g/mL (SD 0.185) with a casein/protein ratio of 0.783 (SD 0.007).

SAT, UNSAT, MONO, POLY mean values were, respectively, 2.569 g/100g (SD 0.404), 1.233 g/100g (SD 0.272), 1.129 g/100g (SD 0.248), 0.150 g/100g (SD 0.040).

The class of major frequency for SAT and UNSAT was 2.7 g/100g (1.9-3.65) and 1.2 g/100g (0.95-2.45).

Comparing the results on milk produced in tie-stalls located in valley (April-May) vs summer pastures (June-July) mean values of fat increased from 4.01 to 4.35/100g, despite of the adaptation to the pasture, probably compensated by a better animal welfare.

It is interesting to remark that UNSAT-SAT mean ratio on 189 BTMS increased from 0.42 to 0.57 g/100g ($p < 0.05$) during the grazing period. MONO and POLY mean values increased, respectively, from 1.00 to 1.28 g/100g and from 0.12 to 0.17 g/100g ($p < 0.05$).

The 37 dairy herds grazing dairy herds were also compared with 54 intensive dairy herds located in flat area during the same period, in order to evaluate variation in fatty acid composition, depending on the type of feeding. Fat mean value was slightly different (4.01 vs 3.96g/100g), while UNSAT-SAT mean ratio, 0.57 vs 0.44 g/100 g, resulted quite different ($p < 0.05$).

Conclusions: The survey confirms the close positive relationship between the grass feeding on summer alpine pastures and fatty acid composition in the milk, that are significantly higher than in fall-winter season. There is the evidence that milk produced using grazing pastures is characterized by UNSAT-SAT mean ratio higher than dairy herds in flat territory using uni-feed. Particularly, UNSAT-SAT mean ratio can represent an important index to evaluate the milk quality oriented to the cheese production and to qualify the nutritive value of the typical dairy products.

New Diagnostic Tool for the Detection and Quantification of Pathogenic Bacteria in Bovine Milk Samples from Dairy Farms in UK

Anna Targa ¹; Alex Gomez ¹; Daniel Zalduendo ¹

¹Laboratorios HIPRA SA, Amer (GIRONA), Spain

Objectives: Using a FTA Card milk sample for PCR-RT testing (STARTCHECK®) is a reliable diagnostic tool that uses a new methodology to collect milk samples and detect the major mastitis causative agents. PCR-RT testing (STARTCHECK®) can be used to complement Somatic Cell Count (SCC) and Bacterial culture to monitor mastitis at a herd level(1). This tool (STARTCHECK®) has been used worldwide since 2009 and milk samples from 44 different countries have been analysed. The aim of this study is to show the results obtained in UK dairy farms.

Materials and Methods: A total of 366 Bulk Tank Milk (BTM) and Mastitis Pool samples were collected from different dairy farms in UK. The samples were taken according to the kit (STARTCHECK®) instructions [Impregnating the designated areas (BTM and Mastitis Pool) on the FTA card with 250ul of the respective milk sample](2) and sent by ordinary mail to DIAGNOS (HIPRA) in Amer, Girona, Spain. (Fig. 1).

The samples were processed and tested using the Real-Time Multiplex PCR assay as previously described (2), to detect the presence of *Staphylococcus aureus*, *Escherichia coli*, Coagulase Negative Staphylococci (CNS) and Coliform bacteria. The results were determined as positive or negative based on Cycle threshold (Ct) values, with Ct values below 37 being considered as positive.

Results: All samples collected in the UK using this tool (STARTCHECK®) were analysed in the specialized HIPRA facilities by using a PCR-Real Time test. Results were obtained in a semiquantitative way. and the positiveness to each mastitic pathogen was as follows:

- 98% of the bulk tank milk samples were positive to Coagulase Negative Staphylococcae
- 63% of the bulk tank milk samples were positive samples to *E. coli*
- 13% of the bulk tank milk samples were positive samples to other coliforms
- 22% of the bulk tank milk samples were positive samples to *Staphylococcus aureus*

Conclusions: FTA Card milk sample for PCR-RT testing (STARTCHECK®) is a good diagnostic tool to identify pathogenic bacteria present in milk samples. The high specificity and sensitivity circumvents limitations experienced with bacteriology (1). Compared with worldwide data, it should be noted that the presence of *Staph. aureus* in UK samples (22%) is higher than samples obtained from other countries (6-10%) (2) Further data will be discussed in more detail during the WBC congress.

P01-001-222

Prevalence And Resistance Trends Of Causative Agents Of Bovine Subclinical Mastitis Over A 10-Year Period In Northwestern Croatia

Dražen Đuričić¹Romana Turk²Hrvoje Valpotić³Damjan Gračner⁴Luka Cvetnić⁵Marko Samardžija⁶*

¹Veterinary Practice Đurđevac, Veterinary Practice Đurđevac, Đurđevac, ²Department of Pathophysiology, ³Department of Animal Nutrition, ⁴Clinic for Internal Diseases, Faculty of Veterinary Medicine, ⁵Department for Bacteriology, Mastitis and Milk Quality, Croatian Veterinary Institute, ⁶Clinic for Obstetrics and Reproduction, Faculty of Veterinary Medicine, Zagreb, Croatia

Objectives: The aim of this study was to determine causative agents of bovine subclinical mastitis (BSM) over a 10-year period (2001-2010), their prevalence and in vitro resistance to antibiotics. Additionally, we monitored the influence of farm size and management system changes during the observation period on the incidence of BSM and effectiveness of antibiotic therapy.

Materials and Methods: Milk samples for microbiological examination were taken from udder quarters of cows without clinical symptoms of mastitis kept at dairy farms in northwestern Croatia that were positive to California or Zagreb mastitis reagents. Prior to sampling, the first milk steams were discarded and the next were examined with the mastitis reagent. When positive reactions were obtained with either mastitis reagent (colour or density change), teat ends were disinfected with cotton swabs soaked in 70% alcohol and new milk samples were collected. The samples were transported in cooled refrigerators to the laboratory as soon as possible. Microbiological agents and antibiograms were performed at the Croatian Veterinary Institute,

Krizevci, Croatia according to common standard protocols. A total of 426 milk samples from dairy cows were examined for the presence of BSM causative agents.

Results: From the total collected samples (n=426), the prevalence of causative agents of BSM was recorded as follows: 44.70% *Staphylococcus aureus*, 24.70% *Staphylococcus sp.*, 9.64% *Streptococcus dysgalactiae*, 4.47% *Streptococcus agalactiae*, 3.76% *Streptococcus sp.*, 6.82% *Escherichia coli*, 1.88% *Enterobacter sp.*, 0.70% *Pseudomonas aeruginosa*, 2.35% *Bacillus sp.*, 0.47% *Candida sp.* and 0.23% yeasts. The prevalence of streptococcal BSM decreased from 30.77% to 10.77% during the 10-year observation period, while BSM caused by *Staphylococcus spp.* increased from 42.31% to 80.00%. Commercial discs were used to perform the antibiogram with the following antibiotics and chemotherapeutics: amoxicillin/klavulanic acid, ampicillin, cefoperazone, cephalixin, cefquinom, enrofloxacin, kloxacillin, lincomycin, neomycin, novobiocin, penicillin, streptomycin, sulphonamide/trimethoprim and tetracycline. After prolonged use of some of these antibiotics for intramammary treatment of BSM, bacterial resistance developed. Namely, only 7.69% of all bacteria isolated were resistant to amoxicillin and klavulanic acid in the first year of the study (2001), while this increased to 38.46% after 10 years. Resistance to some antibiotics increased from 2001 to 2010 was as follows: cefaperazone (0% vs. 15.38%), cephalixin (0% vs. 40.00%), cefquinom (0% vs. 21.53%) and penicillin (19.23% vs. 49.23%).

Conclusions: It could be concluded that during the 10-year observation period, the incidence of BSM caused by *Staphylococci spp.* was significantly increased, as was the resistance of bacteria to certain antibiotics, as a consequence of their frequent use at larger dairy farms (more than 50 cows per farm) and the easier spread of bacteria within and between larger herds in comparison to the beginning of the study when dairy farms in northwestern Croatia were predominately smaller (1-10 cows per farm).

Udder Health & Milk Quality

P01-001-223

Association between etiology of clinical mastitis and characteristics of dairy cows

Tiago Tomazi¹Alessandra M. Orsi¹Gabriel C. Ferreira¹Eduarda B. Bernardes¹Ana C. C. Henrique¹Cristian M. M. R. Martins¹Juliano L. Gonçalves¹Marcos V. Santos¹*

¹Department of Nutrition and Animal Production, University of São Paulo, Pirassununga-SP, Brazil

Objectives: The objective of this study was to evaluate the association between etiological profile of clinical mastitis and characteristics of affected cows (average milk yield, stage of lactation and number of lactation) in dairy herds.

Materials and Methods: Milk samples from all clinical mastitis cases were collected aseptically during 12 months from 20 dairy herds, which had an average of 218 (SD ± 325) lactating cows, and submitted to bacteriological culture. The microbiological results were categorized as gram-positive, gram-negative and non-bacterial microorganisms (yeast and *Prothotheca spp.*) named in this study as "other microorganisms". Only positive cultures with isolation of a unique pathogen were evaluated in this study. Mixed cultures (n=16; two microorganisms isolated from the same sample) and contaminated samples (n=113; more than two microorganisms isolated from the same sample) were excluded from the analysis. During the sample collection, data at the cow level as the

average milk yield before the occurrence of clinical case, parity and days in milk (DIM) were recorded. The effect of selected explanatory variables on risk of isolation of etiological groups of clinical mastitis was tested using logistic regression. The explanatory categorical variables used in statistical models were milk yield (≤ 20 , 21 to 35, and >35 L/cow/d), stage of lactation (early: ≤ 100 ; middle: 101 to 200; and, late: >200 DIM), and parity (1, 2, and ≥ 3 lactations). The models contained herd as a random effect to correct for clustering of cows within herds. Odds ratios (OR) were calculated with 95% confidence interval and the statistical significance was defined as $P \leq 0.05$.

Results: A total of 3,703 milk samples were submitted to microbiological culture during the study period and 2,151 cultures had isolation of a unique pathogen. Of this total, 1,515 cases (70.44%) had isolation of gram-positive bacteria, 520 cases (24.17%) of gram-negative bacteria, and 116 cases had isolation of other microorganisms. Cows in early stage of lactation were 1.36 and 1.68 times more likely ($P=0.001$) to present a clinical mastitis caused by gram-negative bacteria than cows in middle and late stages of lactation, respectively. On the other hand, cows in middle and late stages of lactation were 0.74 and 0.72 times more likely ($P=0.02$) to have a clinical mastitis caused by gram-positive bacteria compared to cows in early stage of lactation. Cows in early and middle stages of lactation were 2.66 and 3.00 times more likely ($P=0.006$) to have a clinical mastitis caused by other microorganisms than cows in late stage of lactation. In addition, first-lactation cows were 2.69 and 2.96 times more likely ($P=0.0003$) to present a clinical mastitis caused by other microorganisms compared to cows that were in second and third or greater lactation. There was no association between gram-positive and gram-negative bacteria and parity of affected cows. In addition, there was no association between the causative groups of clinical mastitis and the average milk yield before the occurrence of clinical mastitis in dairy cows.

Conclusions: Gram-negative bacteria are more likely to cause clinical mastitis in early stage of lactation, while gram-positive bacteria are more likely to cause clinical mastitis in the middle and late stages of lactation. In addition, *Prototheca* spp. and yeast are more likely to cause clinical mastitis in primiparous cows and during the early and middle stages of lactation.

Comments: Acknowledgments: The authors acknowledge FAPESP for the scholarship (Proc. 2013/22286-3) and project funding (Proc. 2014/17411-6).

P01-001-224

Genetic and Economic Analysis for the Relationship between Udder Health and Milk Production Traits in Friesian Cows

Elsaid Z.M. Oudah^{1,*}

¹Department of Animal Production, Faculty of Agriculture, Mansoura University, PC 35516, Mansoura, Egypt

Objectives: The aims of this study were to evaluate the genetic and phenotypic relationship between milk production traits and udder health traits, estimation of genetic parameters for these traits and estimation of the economic milk losses due to bad udder health traits in Friesian cattle raised in a governmental farm in Egypt.

Materials and Methods: The present study used data from the monthly lactation records of Friesian cows belonging to Sakha Animal

Production Research Station, Animal Production Research Institute (APRI), Ministry of Agriculture situated at Kafrelsheikh Governorate in the northern part of Nile Delta of Egypt. Initially, the number of records used was 7,450 monthly lactations involving 784 Friesian cows sired by 89 sires. Excluding some incomplete records and trait limitations (e.i, cows were removed with i) no measurements on yields of milk, fat and protein or with records from <240 , d and >400 , d length of lactation; ii) duplicate termination codes and iii) duplicate records) the final total number of records used in the statistical analyses was 4,752 of 439 Friesian cows sired by 52 sires. Milk production traits : The averages of daily milk yield, monthly milk yield and 305-day milk yield were calculated for each cow. Daily milk yield was calculated as the 305 day milk yield divided by days in milk. Milk samples were taken weekly from each cow for chemical analysis of the milk constituents which included: percentages of fat, protein, lactose, total solids and solid non-fat (SNF). The following milk production traits were studied: 305-day milk yield (305-dMY, Kg), 305-day fat yield (305-dFY, kg) and 305-day protein yield (305-dPY, kg). Somatic cell count (SCC) : SCC was measured by a Fossomatic Cell counter from a sample of the milk collected during the morning milking. The determination of SCC (by thousand cells per millimeter milk) was performed at Dairy Service Unit belonging to APRI, Sakha.

Results: Overall unadjusted means of 305-day milk yield, 305-day fat yield, 305-day protein yield and somatic cell count across lactations were $3,936 \pm 1,044$, 121 ± 54.3 , 90 ± 38.0 kg and 453 ± 218 thousand cell/ml. The coefficients of variation for the same traits were 26.6, 44.8, 42.2 and 48.1%, respectively. Most studied milk production traits were affected negatively, at different levels, in UDHS classes (1 to 9 classes) when compared with the normal udder (0 class). It could be noticed also from Table 2 that 85.1% of observations in this herd (4,045 records from 4,752) had normal udder (0 class). Clinical mastitis represented the highest percentage of UDHS defects (class number 3) with 10.2% of all observations. Meanwhile, the other eight classes (excluding normal udder and clinical mastitis) represented 4.7% of all observations. The highest losses in milk production traits were associated with chronic mastitis treatment (class No. 7) which had the highest negative least square constants (-570 kg for 305 dMY, -9.96 kg for 305 dFY and -9.19 kg for 305 dPY) followed by clinical mastitis (class No. 3) with the 2nd rank of the negative least squares constants (-193 kg for 305-dMY, -5.49 kg for 305-dFY and -3.45 kg for 305-dPY) when compared with the other UDHS defects. The majority of observations (85.1%) were with normal udder (0 class) as reported in (Table 2). The percentages of udders with one quarter infected were 0.84 and 0.95% for right and left fore quarters (classes 1 and 2), respectively and 2.02 and 3.14% for right and left hind quarters (classes 3 and 4), respectively.

Conclusions: it can be concluded that the economic losses from mastitis and high SCC are considerable. Heritability estimate for mastitis is low (0.14). There is an unfavorable genetic correlation between udder health and milk production traits and this emphasizes the need to include mastitis resistance in the breeding goal. Accuracy of selection can be increased by combining information on MAST and SCC, which are rather strongly genetically correlated (0.85) the high genetic correlation between SCC and clinical mastitis suggest that the selection for lower SCC would help to reduce or eliminate the undesirable correlated responses of clinical mastitis.

Udder Health & Milk Quality

P01-001-225

Evaluation of a Chromogenic On-farm Culture System for Fast Identification of Milk Pathogens Associated with Clinical Mastitis in Dairy Cows

Erika Ganda ¹, Rafael Bisinotto ¹, Dean Decter ¹, Rodrigo Bicalho ¹

¹Population Medicine and Diagnostic Sciences, Cornell University, Ithaca, United States

Objectives: Objectives were to evaluate the use of a selective chromogenic culture system designed for identification of specific mastitis pathogens: Staphylococci, Streptococci, and Gram-negative bacteria, constituted by a single plate containing three selective chromogenic media (Accumast® - FERA Animal Health LCC, Ithaca, NY). Predictive values of this method were evaluated in a first set of samples based on aerobic culture results from an official diagnostic laboratory used as gold standard and on a second set of samples through molecular identification of cultured pathogens using 16S rRNA sequencing as gold standard.

Materials and Methods: A total of 538 mastitic milk samples was collected by trained farm personnel following recommendations of the National Mastitis Council and plated onto Accumast® using a sterile cotton swab. Plates were incubated at 37°C for 24 h and read on-farm according to the flowchart provided. Immediately after collection and plating on-farm, milk samples were refrigerated and transported to the QMPS laboratory (Cornell University, Ithaca, NY). Milk samples were cultured following standard procedures and microbiological culture results were used as gold standard. Sensitivity (Se), specificity (Sp), positive predictive value (PPV), and negative predictive value (NPV) were calculated comparing results from on-farm culture and reference laboratory results using the same milk samples. Accuracy was calculated by dividing the number of true positives and true negatives by the total number of tests. The agreement between reference laboratory and on-farm culture was assessed through simple Cohen's kappa coefficient (κ) using the FREQ procedure of SAS.

A second set of samples underwent 16S rRNA sequencing. Plates were read at the farm and those with bacterial growth were transported at room temperature to the laboratory for bacterial isolation, DNA extraction, amplification and sequencing of the 16S rRNA gene using the Illumina platform. Reads were aligned to the Illumina-curated version of Greengenes database for genus-level classification. The PPV and agreement between sequencing and Accumast® were assessed as previously described using 16S rRNA results as a gold standard.

Results: In the present study, the most prevalent pathogens in mastitic milk according to results from QMPS laboratory culture were *S. uberis* (24.9%), *Streptococcus* sp. (10.4%), and *E. coli* (9.1%). Aerobic culture resulting in no bacterial growth accounted for 31.2% of samples cultured, and the prevalence of *S. aureus* was 1.3%. The use of on-farm culture resulted in high overall sensitivity, specificity, PPV, NPV, and accuracy when compared to standard microbiological culture for identification of mastitis pathogens. The Se, Sp, PPV, NPV, accuracy, and κ were 81.6%, 98.9%, 92.5%, 97%, 96.4% and 84.7% for the identification of Gram-negative bacteria, 100%, 99.8%, 87.5%, 100%, 99.8%, and 93.2% for the identification of *S. aureus*, 70%, 95%, 45.7%, 98.1%, 93.6%, and 52% for the identification of *Staphylococcus* sp. and 90%, 92.9%, 91.8%, 91.2%, 91.5%, and 82.9% for the identification *Streptococcus* sp. All P-values associated with kappa coefficients were <0.001 .

The overall PPV and κ of Accumast® when compared to 16S rRNA sequencing was 96.7% and 85.7% for *Escherichia*, 100% and 100% for *Enterococcus*., 100% and 95.3% for Other Gram-negatives., 88.2% and 93.2% for *Staphylococcus* sp., and 95.0% and 91.8% for *Streptococcus* sp.

Conclusions: Color based identification of bacteria enables individuals with limited microbiological training to easily interpret culture results. The culture system evaluated here provides a unique approach for on-farm identification of mastitis associated pathogens, providing the basis for selective antimicrobial therapy of mastitic cows according to the pathogen causing the infection. Overall accuracy was 84.9%, Sensitivity was 82.3%, and Specificity was 89.9% for identifying mastitis pathogens compared with results from standard laboratory. Test characteristics of the method were confirmed through 16S rRNA gene sequencing.

Comparison of PCRs to culture results in detection of Mycoplasma spp. from milk samples from South Australia

Abd Al-Bar Al-Farha ¹, Farhid Hemmatzadeh ¹, Manouchehr Khazandi

²Darren Trott ²Andrew Hoare ³Kiro Petrovski ^{1 2 2 2}

¹School of Animal and Veterinary Sciences, ²The University of Adelaide, Roseworthy, ³South East Vets, Mt Gambier, Australia

Objectives: The objectives of this study were to estimate and compare the detection capability of a novel PCR with traditional bacteriological culture method of *Mycoplasma* spp from cow milk samples collected from a single dairy farm in Mount Gambier, South Australia, Australia. The farm had a high incidence of clinical mastitis but also many cows with a high SCC and the treatment with antimicrobials was of little value.

Materials and Methods: A total of 366 milk samples at cow level were used. Samples originated from cows aged 2-10 years from the hospital mob of the farm with 2400 milking cows. Approximately 5 mL of milk per cow were placed immediately for enrichment into a *Mycoplasma*-selective media broth. At the lab, samples were incubated anaerobically with 10% CO₂ at 37°C. Seven days later, the samples were plated on *Mycoplasma*-selective agar. The presence of *Mycoplasma* colonies was detected using light microscopy at 10x magnification. The DNA was extracted using original milk samples and a PCR technique was used to detect the presence of *Mycoplasma* spp. using specific primers for *Mycoplasma* (16S RNA).

Results of both procedures were compared using kappa agreement. Test characteristics of each test were also assessed. Unfortunately, no gold standard for detecting *Mycoplasma* spp. exists. Therefore, our 'gold standard' was any positive sample detected by either procedure.

Results: *Mycoplasma* species was isolated from 184/366 (50.2%) of mastitis milk samples using the microscopic bacterial culture method. These samples were considered positive when there is a growing of at least one *Mycoplasma* colony in the plate. *Mycoplasma* spp. was identified more frequently using PCR technique with 219/366 (59.8%). The test characteristics of the culture results were Sp= ; Se= ; ACC= while for the PCR, it were Sp= Se= , ACC= .

THE PCR RESULTS WILL BE AVAILABLE IN LATE MARCH TO EARLY APRIL 2016 THE SE, SP AND ACC OF EACH TEST WILL BE ESTIMATED AFTER PCR RESULT BECOME AVAILABLE

Conclusions: The results of this study indicate the significant difference of the detection of *Mycoplasma* mastitis using the novel PCR technique in comparison with the traditional bacterial culture method. In addition, the accuracy of PCR detection technique particularly for the frozen milk samples may have a great value for veterinarians and farmers dealing with difficult to cure mastitis cases.

Comments: The study is on-going. The culture results are available. The PCR results should be available by late March to early April 2016.

Case Report of the Utilization of a Polyvalent Vaccine for Mastitis in the Dry Period and the Milk Quality and Fertility outcomes

Luís Pinho^{1,2}, Isabel Almeida³, Pedro Meireles^{1,2}

¹SVAExpleite, Lda, Fradelos VNF, ²Veterinary Clinics, ICBAS- University of Oporto, Oporto, ³Promilker, Lda, Aveiro, Portugal

Objectives: Even though mastitis control programs are frequently used in dairy production, mastitis are still one of the most frequently occurring and costly diseases in modern dairy farms (Halasa et al., 2007).

Mastitis monovalent vaccines are widely used in some countries showing significant results in the reduction of severity of clinical signs and duration of infection of environmental mastitis (Wilson et al., 2009). The goal of this study was to evaluate the impact in milk quality, fertility and economic outcome of a polyvalent vaccination protocol for mastitis (Startvac®, Hipra, Barcelona).

Materials and Methods: The study was held in a commercial dairy farm of 450 lactating cows on average, situated in the northwest Portugal. The animals were allocated to each group in an alternating form when entering the dry period (157 in the control group and 159 in the vaccinated group). The first dose was administered 8 weeks prior to calving and the rappel applied 4 weeks later. The period of vaccination occurred between October 2013 and July 2014. Production data, somatic cell count (SCC) and fertility data were compiled in an Excel file for posterior statistical analysis. Animals that were culled or died for other reasons than mastitis were excluded from the final analysis. The average value of the milk production difference between the groups was calculated based on the average price of milk sold during the period of study.

Results: The results obtained showed significant differences between the groups. Concerning the SCC a significant reduction in the average values of the three months for multiparous was observed being more visible on the second month of lactation (342×10^3 cells/ml in control group and 86×10^3 cells/ml in vaccinated group; $p < 0.01$), potentiating milk production. There was also a positive difference of milk production on the three months favouring the vaccinated group although only statistically significant on the second month of test day of the multiparous cows (2.35 L; $p < 0.05$).

In effect, the vaccinated group registered less 52 mastitis cases thus explaining the raise in milk production when compared to the control group.

Concerning the fertility indexes the calving-first insemination interval was 11.5 shorter for multiparous ($p < 0.01$) contributing to the decrease of the calving-conception interval.

On the economic analysis, the vaccine showed a gain of 47.10 € on the first three months of lactation on the multiparous of the vaccinated group. This value was of 21.15€ when just evaluating the second month when the difference was more significant.

Conclusions: This study showed that the utilization of this polyvalent vaccine for mastitis reduced the somatic cell count and improved the milk production of the vaccinated cows. Additionally, less clinical cases were registered during the period of analysis in the vaccinated group. Finally,

the immunized group performed better in terms of fertility indexes, namely, on the reduction of the interval from calving to conception. These results showed that the utilization of this polyvalent mastitis vaccine is an important additional tool to include in the prevention mastitis programs.

In-feed inclusion of clinoptilolite reduces milk aflatoxin M1 concentration in dairy cattle

P.D. Katsoulos¹, M.A. Karatzia¹, C. Boscos¹, H. Karatzias¹

¹Clinic of Farm Animals, School of Veterinary Sciences, Aristotle University of Thessaloniki, Greece, Thessaloniki, Greece

Objectives: Clinoptilolite is a natural zeolite with high adsorption capacity for polar mycotoxins. Its efficacy in ameliorating the toxic effects of aflatoxicosis has been proven in monogastric animals, but no evidence exists for ruminants. The aim of this study was to evaluate, under field conditions, whether the dietary administration of clinoptilolite in dairy cows reduces aflatoxin M1 (AFM₁) concentration in bulk-tank milk, when AFM₁ concentrations were higher than or close to the European maximum allowed residual level ($0.05 \mu\text{g AFM}_1/\text{kg}$ of milk) and investigate whether the particle size could affect clinoptilolite's aflatoxin binding efficacy.

Materials and Methods: The study was conducted in 15 commercial Greek dairy herds that had high concentrations of AFM₁ in bulk tank milk (close to or higher than $0.05 \mu\text{g AFM}_1/\text{kg}$ of milk), as detected at the routine analyses by the dairy industries collecting the milk, using their standard methods of determination. The criteria for the selection of the farms were: a) the willingness of the farmers to use only clinoptilolite as mycotoxin binder without making any other changes to the rations offered to the animals during the experimental period, and b) the agreement of the milk industries to determine the AFM₁ concentrations in the delivered bulk tank milk at fixed time-points. The study lasted 7 days. On Day 0, the bulk tank milk AFM₁ concentration was determined. For the next seven days (Days 1 to 7), clinoptilolite was added in the total mixed rations of all farms at the level of 200 g per animal, per day. The bulk tank milk AFM₁ was also determined at the delivered milk produced on Day 7 of the experiment. According to the size of zeolite used, the farms were allocated into two groups. The first group (SC) was consisted of 9 farms that used the $< 0.15\text{mm}$ particle size and the second one (LC) of the other 6 farms that used the $< 0.8\text{mm}$ size. All statistical analyses were done with SPSS® version 21.

Results: The dietary administration of clinoptilolite for seven consecutive days significantly reduced milk AFM₁ concentrations in all farms tested at an average rate of 56.2 % (SD: 15.11). The mean milk AFM₁ concentration recorded on Day 7 was significantly lower compared to that of Day 0 (mean \pm SE: $0.078 \pm 0.0074 \mu\text{g/kg}$ and $0.036 \pm 0.0061 \mu\text{g/kg}$ for Days 0 and 7, respectively, $P < 0.001$). In farms of the LC group the reduction of milk AFM₁ concentration was significantly higher than in farms of HC group (mean \pm SE: $0.046 \pm 0.0074 \mu\text{g/kg}$ and $0.036 \pm 0.0061 \mu\text{g/kg}$ for groups LC and HC, respectively, $P = 0.002$). As indicated by the Pearson correlation, there was a significant and strong linear correlation among the milk AFM₁ concentrations on Days 0 and 7 ($R = 0.95$, $P < 0.001$). According to the results of regression analysis, the equation yielding the predicting value of milk AFM₁ concentration after the administration of clinoptilolite (Day 7) was:

$$\text{AFM}_{1F} = 0.781 \times \text{AFM}_{10} - 0.023, (r^2 = 0.899, P < 0.001),$$

where AFM_{1F} represents the milk AFM₁ concentration on Day 7 and AFM₁₀ the milk AFM₁ concentration on Day 0.

Conclusions: Dietary administration of clinoptilolite, especially of smallest particle size, can effectively reduce milk AFM₁ concentration in dairy cattle. Taking into consideration that the long-term dietary supplementation of clinoptilolite is safe and has beneficial effects on the health status and productivity of dairy cattle, clinoptilolite feeding at the rate of 200 g per cow per day can be used as a preventive measure for the amelioration of the risks associated with the presence of aflatoxins in the milk of dairy cows.

Udder Health & Milk Quality

P01-001-229

The Overall, Quarters and Herd Size Prevalence of Mastitis in Dairy Buffaloes

Abid Hussain^{1,*}Mansuruddin Ahmad²Muhammad H. Mushtaq²

¹Epidemiology and Public Health, University of veterinary and animal sciences,, ²Epidemiology and Public Health, University of veterinary and animal sciences, lahore, Pakistan

Objectives: Dairy farming in Pakistan is primarily fragmented into traditional rural, progressive/semi-commercial rural, peri-urban and commercial/corporate farming. However, the traditional rural farming is the largest segment among all. The majority of dairy farmers are smallholders with substantial number of landless farmers. The cross sectional study was carried out to investigate the prevalence of clinical and subclinical mastitis in dairy buffaloes.

Materials and Methods: The present study was conducted in two districts Lahore and Bhimber. Total sample size for this survey was consisted of 1,036 lactating buffaloes. The screening of lactating buffaloes was performed with the California Mastitis Test. All the collected data through questionnaire was entered into an Excel sheet of Microsoft Office Excel (2003) and transferred for analysis to R software and SPSS version 16.0. Firstly, all the data were labelled into sub heading and analyzed by using descriptive statistics for the frequency and cross tabulation tables.

Results: The overall prevalence of mastitis was recorded at 49%. Among mastitis cases the prevalence of clinical mastitis was 10.2% (106/1036 animals) as a whole. However, the prevalence of clinical mastitis in district Lahore was 11.8% (71/598 animals) whereas it was 8% (35/438 animals) in district Bhimber. The overall prevalence of subclinical mastitis was 38.8% (402/1036). The district wise prevalence of subclinical mastitis was 43.6% (261/598 animals) and 32.2% (141/438 animals) in the districts of Lahore and Bhimber, respectively. The quarter level prevalence was recorded 16.20% (673/4144 quarters from 1036 animals). The district wise prevalence of mastitis at quarter level was recorded 18.17% (449/2392 quarters) in a district Lahore while, it was 12.87% (224/1752 quarters) in district Bhimber. The overall prevalence of mastitis on the basis of herds size was 41/102 (40.2%), 186/400 (46.5%) and 281/534 (52.6%) in small, medium and large herds, respectively.

Conclusions: Mastitis has great economic losses in the dairy industry and it can be minimized by improving management and milking practices. it can be concluded from the present study, the prevalence of subclinical mastitis is higher then clinical mastitis. the prevalence of mastitis was higher in hind quarters then fore-quarters. The prevalence of mastitis was increased as the herd size is increased.

Using deviation patterns of in-line milk conductivity to automatically detect mastitis caused by specific pathogens during milking

Aurora Villarroel^{1,*}

¹Afimilk, Ltd, Fitchburg, WI 53711, United States

Objectives: The objective of this study was to determine whether there are differences in milk conductivity for mastitis caused by different pathogens, to allow accurate early detection of mastitis during milking. This will allow to treat cows promptly and accurately allowing the cows the best chance for fastest recovery.

Materials and Methods: Milk meters equipped with conductivity probes (Afimilk, Israel) installed on a large commercial farm in Spain were used for data collection; every cow, every milking. Cows identified with mastitis by clinical signs (abnormal milk and/or swollen quarter) were evaluated as to the milk conductivity level (mmHO) on the day of mastitis diagnosis, as well as the deviation of that level compared to the average conductivity of the same milking shift during the previous 10 days for each sepcific cow. A milk sample was collected before treatment and submitted to a reference laboratory for identification of isolated bacteria.

Results: A total of 92 samples were included in the evaluation. On average, cows with mastitis showed a mean conductivity of 13.0±1.4 mmHO compared to 10.1±0.5 mmHO throughout the entire lactation of the whole herd (P<0.001). Cows with mastitis showed a 19% deviation from the average of the previous 10 days. Variations were evident depending on isolated bacteria. Most notably, cows infected with E. coli had higher conductivity deviation (26%) than if infected with other bacteria (19%, P<0.001), while the average conductivity not different between the groups (P=0.745). No other statistically significant differences were observed, although numerical differences were evident between Gram + and Gram - bacteria.

Conclusions: Instead of looking for a fixed conductivity breakpoint in milk conductivity to diagnose a cow with mastitis, milk conductivity can be effectively used to detect mastitis caused by E. coli versus other organisms due to different deviation patterns from the average conductivity of the previous 10 days of each cow.

Population structure of infective *Streptococcus uberis* strains in two farms in northern Portugal

Joao Niza Ribeiro^{1,2,*} on behalf of Niza RibeiroPedro Albuquerque

³Alexandre Almeida⁴Irene Panschin⁴Afonso Porfirio¹Marta Vales

¹Helena Madeira¹Fernando Tavares⁴

¹ICBAS - Population Studies, ²ISPUP, ³CIBIO - Centro de Investigação em Biodiversidade e Recursos Genéticos, InBIO, Laboratório Associado, ⁴FCUP Departamento de Biologia, Porto University, Porto, Portugal

Objectives: Bovine mastitis leads to significant economic losses worldwide. Importance of *Streptococcus uberis* (SU) has increased in udder health. Currently two distinct epidemiologic pattners of SU are

recognized: environmental or contagious. Different control strategies are needed to control these patterns. In this work, persistent infected cows from two dairy herds with high SU infection were followed two consecutive years. Purpose: to isolate, characterize and search for known virulence-associated genes of *S. uberis* in quarter milk. Main objective: to disclose prevailing genotypes of SU focusing on persistency, pathogenicity and population structure.

Materials and Methods: Two dairy herds located in Northern Portugal (Barcelos – herd 1; Maia – herd 2) were visited in two consecutive years (2013 and 2014). In the first visit all the lactating cows were clinically evaluated and California Mastitis Test was carried out at quarter level. Milk samples from each quarter were collected for quantification of SCC (somatic cell count) and bacteriological culture. Preliminary identification of bacterial isolates was performed using the VITEK 2 system and *S. uberis* was identified (bioMérieux, Durham, NC). The infected cows were monitored in the following months and milk from all quarters was screened for the presence of *S. uberis*; CMT and SCC were always done.

Dot blot hybridization assays, coupled with automatic image analysis software, were carried out using 19 DNA probes to characterize the genotypes of *S. uberis* isolates: four taxa-specific probes for *S. uberis* species confirmation; two probes targeting the fructose operon and two the nisin operon; seven probes designed for genes associated to increased virulence and three markers to assess antibiotics resistance.

Multilocus sequence analysis (MLSA) of 30 *S. uberis* isolates was carried out using three housekeeping genes (*ddl*, *gki* and *tdk*). The sequences were concatenated and aligned with the sequences for the same genes of 987 *S. uberis* isolates available at the PubMLST online database. A Neighbor-Joining phylogenetic tree was built to determine the population structure of the *S. uberis* isolates used in this work.

Results: A total of 44 *S. uberis* isolates were obtained from 14 cows (4 from herd 1 and 10 from herd 2) with recurring mastitis infections. After milk testing, while 12 cows showed persistent signs of subclinical mastitis for the duration of the study, two cows presented clinical mastitis.

Dot blot results with the taxa-specific probes confirmed the identity of all isolates as *S. uberis*. Overall, 7 different genotypes were identified in the two herds studied, which had two distinctive profiles. While in herd 1 no prevalent genotype was found, the 30 *S. uberis* isolates from herd 2 had a clearly dominant genotype. The probes addressing antibiotics resistance showed a greater variation amongst isolates. In fact, while the *linB* gene (lincosamide resistance) and *tetS* (tetracycline resistance) were present in 32 *S. uberis* isolates, the *ermB* gene (erythromycin resistance) was present in only 5 isolates.

MLSA characterization showed that these *S. uberis* belong to seven clusters. While in herd 1 a high diversity in *S. uberis* lineages was found, herd 2 was dominantly colonized by the same lineage. Additionally, it was shown that, regardless the herd, recurring infections in 11 from 14 cows were caused by same MLSA cluster. Concerning the two cows with clinical mastitis, while showing different clinical evolution, both remained infected with the same strain for more than five months.

Conclusions: The results obtained in this work suggested distinctive *S. uberis* population structure for the two farms. While in the Herd 1 *S. uberis* were indicative of an environmental pathogen, in Herd 2 the high incidence of a specific *S. uberis* genotype suggests a profile of an infectious pathogen. A transmission pattern was identified in herd 2 and a persistent not transmissible pattern in herd 1; although the two farms are in an intensive system, the cows in herd 1 are allowed to graze outdoors, while in herd 2 they are mostly confined indoors (free stall).

Comments: The authors acknowledge the contribution of Segalab, Laboratório de Sanidade Animal SA the providing the opportunity of following the herds and obtaining the SU strains.

Seasonal variation in milk composition in five dairy herds

Jožica Ježek¹·Marija Nemec¹·Martina Klinkon¹·Jože Starič¹

¹Clinic for ruminants with ambulatory clinic, University of Ljubljana, Veterinary faculty, 1000 Ljubljana, Slovenia

Objectives: Milk composition may be a useful tool for early detection of nutritional and health problems in a dairy herd. Seasonal variation in milk components is a recognised phenomenon. The results of weekly bulk milk samples during one year period were analysed.

Materials and Methods: Bulk milk samples from five dairy farms with (25-190) dairy cows were taken weekly during one year period. Contents of milk fat, milk protein, lactose, and somatic cell count were measured. Concentration of urea, sodium, potassium, chloride and activity of enzyme lactate dehydrogenase (LDH) was measured in milk serum samples with biochemical analyser Cobas Mira (Roche). Nutrition, health and reproductive status of dairy cows in herds were followed during investigated period. Statistical analysis was performed with programme SPSS (Ver. 22).

Results: The milk fat content was between 4.19±0.18% and 3.63±0.14 with the lowest value in July. The lowest value of milk protein was in June (3.18±0.09%) and the highest values were found from November to February. Variation in lactose content was insignificant. The lowest concentration of urea (3.17±0.88 mmol/L) was measured in April and higher concentrations from June till October with peak in August (4.50±1.18 mmol/L). The concentration of sodium varied between 23.11±2.97 mmol/L in April and 27.31±9.04 mmol/L in June. The concentration of potassium varied between 35.59±1.7 mmol/L in May and 40.35±2.86 mmol/L in November. The concentration of chloride oscillated between 38.85±2.32 mmol/L in February and 43.38±2.53 mmol/L in November. The highest activity of LDH was measured in December (130.59±11.59 U/L) and the lowest activity was found in July (103.93±19.81 U/L). The somatic cell count varied between 258±82 x 10³/ml in October and 384±97 x 10³/ml in May.

Conclusions: Variations in milk composition between herds were observed which were partly related to nutrition and season and partly to the udder health. Detailed analysis of single cows milk composition contributing to these data is planned.

P01-001-233

Sensitivity And Specificity Of Scc In Quarter Milk Samples To Diagnose Intramammary Infections

Paulo Cesar Duque-Madrid¹·Alejandro Ceballos-Marquez¹·Mario Lopez-Benavides²·Marcos Muñoz-Domón³

¹Universidad de Caldas, Manizales, Colombia, ²Delaval, Kansas, United States, ³Universidad de Concepcion, Chillan, Chile

Objectives: Culture results of duplicate quarter milk culture samples have been a common way to determine the infection status of the mammary gland in teat disinfectant clinical trials. In recent years, field trials have evaluated the efficacy of teat disinfectants using a novel

approach that considers a somatic cell count (SCC) threshold to make a culture decision, and to determine intra-mammary infections (IMI). The aim of this study was to evaluate the sensitivity (Se) and specificity (Sp) of SCC as a potential qualifier for milk samples to be cultured, and to test positive for an IMI with mastitis pathogens in clinical trials.

Materials and Methods: Data included cow information, SCC and bacteriological results from the first sampling of ten clinical trials. As part of the trial protocol, first sampling required that all milk samples had SCC and microbiological status information. In total, sterile milk samples of 8,859 quarters from 2,255 cows were analyzed. Trials were conducted in dairy herds located in USA, Canada and Colombia between February 2009 and July 2014. The SCC value from each milk sample was determined using an automated SCC reader. In addition, each milk sample was submitted for aerobic culture following standard procedures (NMC, 1999). The Se, Sp, positive predictive value (PPV) and negative predictive value (NPV) were calculated as described by Dohoo et al. (2009).

Results: Out of the total milk samples cultured, only 27% showed bacterial growth. The most common pathogens were *Staphylococcus* spp (CNS), *Staph. aureus* and *Cor. bovis*. A total of 1,869 (21%) samples had their SCC value above the thresholds set. The receiver operating characteristic (ROC) curve was made to determine the ability of SCC to classify correctly positive quarters, the area under curve was 0.66.

The Se and Sp varied depending on the bacterial species and the cow's lactation number. The overall Se and Sp of SCC to predict milk samples to be cultured was 37.8% (95% CI: 35% - 39%) and 85.3% (95% CI: 84% - 86%), respectively. Both parameters for each bacterium isolated were also calculated. The PPV and NPV of SCC thresholds for all pathogens were 49% (95% CI: 47% - 51%) and 78% (95% CI: 77%>79%), respectively.

The Se according to the isolated pathogen was high when the milk culture was positive for major pathogens (82%; 95% CI: 78% - 86%), such as *Staph. aureus*, *Streptococcus agalactiae* and *Strep. uberis*. However, the Se for minor pathogens was low (29%; 95% CI: 27% - 32%), which would be expected since minor pathogens are normally associated with slight increases in SCC (Schepers et al. 1997).

Conclusions: The new approach in which a threshold of SCC is used as an initial screening test is effective for determining true IMI in clinical trials, mostly caused by major pathogens. The relevance of identifying minor pathogens needs further research. Using this approach, the cost associated with the analyses in traditional trials to test teat disinfectants might be reduced.

P01-001-234

Prevalence and Management Practices associated with Bulk Tank Milk Prevalence of *Staphylococcus Aureus* and Coliforms in Azorean Dairy Herds

Diana Pacheco¹Luisa Soares¹Mónica Moitoso¹Roger Guix²Jaime Maldonado²João Simões³Carla Azevedo^{2*}

¹AJAM, São Miguel, Portugal, ²HIPRA, Amer, Spain, ³UTAD, Vila Real, Portugal

Objectives: The aims of the present study were: 1) to determine the apparent prevalence of some of the main microorganisms that cause mastitis - *Staphylococcus aureus*, *Escherichia coli* and other coliforms (COL) from bulk tank milk (BTM) samples of dairy farms on

the island of São Miguel- Azores, and; 2) to evaluate the management milking practices associated with these pathogens prevalence, and consequently, the ultimate goal was to emphasize the indication, in Azorean dairy farms, for the use of the first vaccine registered by EMA (European Medicine Agency) for the prevention of mastitis caused by these pathogens (STARTVAC®, HIPRA, Spain).

Materials and Methods: In July, 2014, 100 dairy herds considering a total of 6065 adult cows were used from all regions of San Miguel. These animals represented 11.7% (51.684) of whole adults dairy cows on pasture from 5.5% (1833) herds, according data officially reported in São Miguel Island.

A total of 100 BTM samples from the 100 selected herds were collected using a qPCR commercial sampling kit (Startcheck®, HIPRA, Spain), according the manufacturer instructions, in order to test the presence of *S. aureus*, *E. coli* and COL. A qPCR positive result was recorded when cycle threshold values were ≤ 37 and a sigmoidal amplification plot was obtained. Simultaneously, a questionnaire on management practices was carried out according to 5 main groups: 1) the hygiene of the milking procedures, 2) milking machine and tank 3) diagnosis and treatment of mastitis, 4) drying off, and 5) management of calves. A logistic regression analysis was used in order to evaluate the effect of management practices on pathogens BTM prevalence.

Results: *S. aureus*, *E. coli* and COL were detected in 59%, 75% and 35% of BTM, respectively. Of the BTM positive samples, 79.7 % (47/59) were concomitantly positive for *S. aureus* and *E. coli*, and 42.4 % (25/59) to *S. aureus* and COL. *E. coli* and COL were detected simultaneously in 38.7 % (29/75) of the samples. On herds without routine use of gloves and pre-dipping during milking, or not using hot water for cleaning the milking utensils, there was at least 2.8 more chance (P ≤ 0.05) to present *S. aureus* or COL contamination on BTM. Herds without cleanliness practices of udder, teats or tail, milking mastitic and healthy cows together, and lacking treatment records were more affected (P ≤ 0.05) by the presence of *S. aureus* on BTM. The use of mobile (unrefrigerated) BTM also favored (odds ratio = 3.7; P ≤ 0.01) the detection of COL on BTM.

Conclusions: We have presented baseline figures for major contagious and environmental pathogens in BTM samples from Azorean dairy herds and evidenced that some milking management practices represent risk factors for the detection of these pathogens in BTM. These results should be considered in the design of mastitis prevention and control plans for the control of milk quality and suggest that vaccination for the prevention of mastitis can be a real asset as an additional tool in a mastitis control plan in the Azorean dairy herds.

Early Administration of an Internal Teat Sealant to Maiden Dairy Heifers

Greg Chambers¹Hamish Newton^{2*}

¹Zoetis NZ, Cambridge, ²Veterinary Centre, Oamaru, New Zealand

Objectives: Precalving administration of internal teat sealant (ITS) to maiden dairy heifers is a widespread practice in NZ and it is mostly performed by veterinarians and trained technicians. The purpose of this study was to assess whether extending the sealing-calving interval, by starting earlier in relation to calving, affects the risk of clinical mastitis (CM) between sealing and calving (to assess the risk of iatrogenic mastitis) or in the first 30 days of lactation (to assess efficacy). If the

interval can be extended without compromising safety or efficacy, veterinary clinics could start heifer ITS administration earlier and better meet demand.

Materials and Methods: All heifers that had ITS (Teatseal®, Zoetis NZ) administered by the clinic (Veterinary Centre Oamaru, NZ) ITS team through a specialised trailer over the winter of 2014 were eligible for enrolment in this observational study. Farms were excluded if the farm did not use the MINDA data management program (LIC NZ) or if the farm records were not deemed to be accurate. Heifers were excluded if all four teats were not sealed or no calving date was recorded. Each farm's heifers were sealed on a single calendar day. CM data were captured between sealing and 31st October 2014. A CM case was defined as any case of CM identified and treated by farm staff according to each farm's standard practice. As date of sealing, and therefore sealing-calving interval, are clustered data (by farm), a mixed effects logistic regression was run with farm as a random effect. The data were analysed in two ways. Firstly, mixed effects logistic regression was used to assess the effect of sealing-calving interval on the risk of CM pre-calving and in the first 30 days post-calving. Secondly, heifers were dichotomised around a time point of four weeks prior to planned start of calving into "early" (before four weeks prior to PSC) and "label" (the remainder) groups, and the same risks were compared by mixed effects logistic regression.

Results: 7166 heifers from 31 farms met the inclusion criteria. Heifer ITS administration was performed between 9th May and 11th July 2014 (range 63 days). Sealing-calving interval ranged from 0 to 145 days (mean 53, median 51). 17 cases of pre-calving CM (0.2%) and 370 cases of CM between calving and 30 days postpartum (5.2%) were reported. The median and mean time to CM in the first 30 days postpartum were 3 and 6 days respectively. Heifers with a longer sealing-calving interval had a numerically lower risk of CM in the first 30 days postpartum but this was not statistically significant (OR = 1.00 (0.99 - 1.01), p= 0.58). Heifers in the "early" and "label" groups were on average sealed for 65 days and 35 days respectively. Heifers in the "early" group had a numerically lower risk of CM in the first 30 days postpartum but this was not statistically significant (OR = 0.80 (0.35 -1.79), p=0.58.) There were insufficient cases of pre-calving CM to draw conclusions about the effect of sealing-calving interval on precalving CM risk. The ITS administration technicians found no difference in ease of administration or proportion of blind quarters with respect to timing of administration.

Conclusions: Commencing ITS administration of NZ spring calving heifers from early May did not increase the risk of CM in the first 30 days of lactation. There was very little CM between sealing and calving, making it difficult to draw any firm conclusions about the risk of precalving mastitis when administering ITS early. However, the fact that the incidence of pre calving mastitis in heifers sealed early was low per se supports the safety of this practice. A limitation of this study is that it is observational which resulted in much of the variation in sealing to calving time explained by farm, as all heifers on a farm were sealed on one day.

Mastitis Vaccination using a Commercial Polyvalent Vaccine or a Herd-Specific Staphylococcus Aureus Vaccine – Results of a Controlled Field Trial

Markus Freick¹, Yvonne Frank², Kathrin Steinert³, Ahmad Hamedy⁴, Oliver Passarge¹, Axel Sobiraj²

¹Veterinary Practice Zettlitz, Zettlitz OT Methau, ²Faculty of Veterinary

Medicine, Large Animal Clinic for Theriogenology and Ambulatory Services, Leipzig, ³formerly: LKS mbH, Lichtenwalde, ⁴Faculty of Veterinary Medicine, Institute of Food Hygiene, Leipzig, Germany

Objectives: Mastitis caused by staphylococci is counted among the most important infectious diseases in dairy cows worldwide. More than 80% of all antibiotics used in dairy farming are applied for the treatment or metaphylaxis of mastitis. Frequently, antibiotic mastitis therapies are not of satisfactory success and can promote the selection of antibiotic-resistant bacteria. Thus, the objective of this study was to reduce the number of mastitis treatments during lactation and to decrease the proportion of cows with elevated individual cow somatic cell counts (ICSCC) at time of dairy herd improvement tests (DHITs) by mastitis vaccination.

Materials and Methods: Motivation of this field trial was an elevated bulk milk somatic cell count (BMSCC) and the detection of *S. aureus* as predominant mastitis causing pathogen in a Saxon dairy herd. The study was designed as a prospective, randomized, controlled and partially blinded parallel group comparison. Deliberately, accompanying procedures were neglected especially as housing, feeding, and milking hygiene were already at a high level.

According to the results of cytobacteriological investigations of quarter milk samples one week before dry cow therapy and including data of preceded DHITs, cows were stratified into the status groups (SG) 2-4 according to their udder health. Heifers were classified as SG 1. Heifers (n=181) and cows (n=416) were randomized within their SG to one of the following vaccine groups (VG): Startvac® (HIPRA Deutschland GmbH) (VG SV), Bestvac® Rind Mastitis (containing herd-specific *S. aureus*-strains; IDT Biologika GmbH) (VG BV) and unvaccinated control (VG Co). On average, the first vaccination was performed at 223rd and the second vaccination at 247th day of pregnancy, and finally, the third vaccination at 53rd day in milk (DIM).

Statistical analysis of the common logarithmized ICSCCs (ICSCC_{log}) and milk yield of DHITs 1-4 was performed. Furthermore, ICSCCs of the DHITs 1-4 were categorized regarding to the categories ICSCC<200000/ml, 200000/ml≤ICSCC<700000/ml and ICSCC≥700000/ml and the distribution was analyzed statistically. Finally, the mastitis therapy frequencies at quarter and cow level as well as the duration of therapies were documented until 305th DIM.

Results: The DIM of the cows within the several groups did not differ significantly (mean: DHIT 1 - 34 DIM, DHIT 2 - 68 DIM, DHIT 3 - 101 DIM, DHIT 4 - 135 DIM) (p=0,126 to p=0,867). Considering the means of milk yield, no significant difference was detected between the VG within SG 1-3 at the four DHIT days (p=0,168 to p=0,919). However, at DHIT 1 it was significant within SG 4 that milk yield of VG SV was lower than in the compared groups (p=0,046). Statistical analysis of ICSCC_{log} of DHITs 1-4 revealed no significant differences of the VG within their SG (p=0,113 to p=0,909). The distributions of the ICSCC of the VG within their SG regarding to the categories ICSCC<200000/ml, 200000/ml≤ICSCC<700000/ml and ICSCC≥700000/ml did not differ significantly (p=0,127 to p=0,843).

Due to the small amount of clinical mastitis data only a descriptive analysis was conducted. There were no obvious differences in the incidence of clinical mastitis and duration of a necessary mastitis therapy, respectively, between the VG within their SG.

Conclusions: Since positive effects concerning the SCC were absent in the own trial as well as in the studies of Bradley et al. (2015) (Startvac®) and Hoedemaker et al. (2001) (herd-specific *S. aureus* vaccine), mastitis vaccines against staphylococci are not a suitable tool to decrease the ICSCCs and, thus, to reduce BMSCC within an appropriate period of time on farms with good udder health management and high hygiene standards. In fact, the expectations should be focused on the reduction

of severe clinical mastitis cases (Bradley et al. 2015) or a long-term reduction of the basis reproduction rate of staphylococci on herd level (Schukken et al. 2014).

P01-001-237

Evaluation of Two Drying Off Methods in Dairy Goats at the end of lactation.

Salvador Avila Téllez^{1*} and Gutierrez M.G.J.; Navarro E. J.A.; Espinosa C.L.F.; Romero M.J.; Barajas R.J.A.; Rosiles R.R.

¹Departamento de Medicina y Zootecnia de Rumiantes, Facultad de Medicina Veterinaria y Zootecnia, UNAM, México Distrito Federal, Mexico

Objectives: To demonstrate the effectiveness of two dry off methods in goats: Group G1 was given an antibiotic therapy and Group G2 an antibiotic therapy followed by bismuth subnitrate at goat drying to reduce the number of animals affected with mastitis.

Materials and Methods: This study was carried out in dairy goat farms, located in the highlands of Mexico. Fifty-four dairy goats (108 glands) were sampled from following goat breeds: Saanen, Toggenburg and French Alpine, producing an average of 500 ml of milk per day, before dry. The animals were classified in two randomized groups, G1 (control group) of 29 goats (58 glands), and group G2 of 25 goats (50 glands). All goats were clinically examined, paying particular attention to udder health. Prior to milking, milk samples were collected from each gland and somatic cell count was determined through CMT, and at the same time with flow cytometry. The drugs used were selected based on in vitro antibiotic susceptibility results in milk for each gland. The dry off period consisted on an abrupt cessation of milking, accompanied by diet change and accommodation area. About two days prior to goat parturition, a cap of bismuth subnitrate was removed. Five days after parturition, milk samples were obtained for bacterial sensitivity and SCC were performed at this time. The percentage difference between negative and positive group mastitis in both cases, drying off and parturition, was performed using the following formula: $\% = ((CF / CI) - 1) \times 100$. The analysis of the corresponding proportions between the steps of drying off and parturition in each treatment was performed through bilateral contrast chi-square, χ^2 statistical significance level of $\alpha = 0.05$.

Results: One hundred and eight goat glands (G1 and G2) were tested at dry off period; among them, 35 glands resulted mastitis negative, and at parturition, 91 glands represented an increase of 184.4% negative cases. At dry off period, 73 glands were positive for subclinical mastitis and at parturition, 16 glands resulted mastitis positive, which represent a 78% decrease. Milk samples collected during the study in both groups showed *Staphylococcus aureus* and *Streptococcus uberis*. Group G1 (only antibiotic therapy) showed 8.62% for positive cultures at dry off, and at parturition, 15.51%; in comparison with group G2 that showed 6% for positive cultures at dry off, and 2% at parturition. Analyzing subclinical mastitis, in group G1 a decrease of 70% was observed; versus in group G2 (Antibiotic treatment and sealant) that showed a decrease of 83%.

Conclusions: The antimicrobial therapy application followed by bismuth subnitrate provided a higher reduction in clinical mastitis versus just the administration of antibiotic therapy.

Bacteriological tests were conducted at the Laboratory of the Department of Medicine of Ruminants -FMVZ-UNAM

(Where: CF = final cases, CI = initial cases - 1 is the constant)

P04-004-204

Efficacy And Economics Of A Polyvalent Mastitis Vaccine

Dirk van Aaken^{1*} Thom Oostenbrug^{1*}

¹Utrecht University, faculty of veterinary medicine, Utrecht, Netherlands

Objectives: Mastitis is an important animal disease causing decreased production and profits on dairy farms. J5 vaccines against gram negative pathogens have been used in the US for over 40 years. Since 2009 a polyvalent vaccine protecting against coliforms, *Staphylococcus aureus* and coagulase negative staphylococci (CNS) has been available in Europe (Startvac®/Topvac®). The objective of this study was to look at the efficacy of this vaccine under field conditions and to estimate the economic consequences of using this vaccine on dairy farms.

Materials and Methods: This abstract is based on the bachelor thesis written by Oostenbrug and Van Aaken in 2013 at Utrecht University, Faculty of Veterinary Medicine. To evaluate the efficacy of this vaccine a literature study with peer reviewed articles was performed. The data extracted from these papers is shown in the results section. For the economic analysis peer reviewed literature as well as case studies were used. The data extracted from these studies were then extrapolated to the Dutch situation in order to calculate costs of mastitis and possible costs and benefits of vaccination.

Results: Vaccine efficacy for coliforms for the first 120 days in milk (DIM) was evaluated in a UK study with over 3000 cows. No difference in incidence of clinical and subclinical mastitis was observed, but the severity of clinical mastitis cases was significantly reduced in the vaccinated groups. Furthermore vaccinated cows produced significantly more milk with higher milk solids than negative controls.

In Italy two herds with a total of 809 cows were vaccinated according to the label regime or left as controls. Vaccinated cows had a lower incidence of new infections with *S. aureus* or CNS and the duration of infection by *S. aureus* or CNS was significantly lower than negative controls. The estimated reproduction ratio (R_0) for *S. aureus* was decreased by 45% and for CNS with 35% compared to negative controls. Estimated vaccine efficacy decreased with increasing lactation number and significant differences between farms were observed.

As a result of the calculation and assumptions made in 2014 in regard to this vaccine, it can only give an annual cost of €40 per cow per year on a farm to be profitable.

In a UK study, vaccination with this vaccine resulted in a return on investment of 2.57:1 and gave an increase in milk production of 231L in the first 120 DIM. Based on the fact that milk production will most probably be the same this is an opportunity to extrapolate these figures for the Dutch situation. The culling rate was reduced with 8% when vaccination was performed. Using the same calculation method as mentioned before, vaccination may only cost €32,- or less to be profitable.

Conclusions: This vaccine has proven being capable of reducing clinical signs of acute coliform mastitis and reducing the reproduction ratio for more chronic mastitis pathogens. Also increased milk production with higher milk solids and reduced culling rates due to mastitis have been observed. Reductions vary between farms, indicating that a mastitis vaccine is not the sole solution for mastitis.

Based on two different studies, vaccination may only cost €32,- or €40,- or less to be profitable. It should be stated that the €32,- estimation is based on the first 120 DIM, indicating that this could be an underestimate for the costs of vaccination.

In practice case study to investigate the effect of selective dry cow treatment on mastitis incidence

Hans Caron ¹ Monique Driese ²

¹Veterinary practice 't Leijdal, Chaam, ²Boehringer Ingelheim, Alkmaar, Netherlands

Objectives: In this case study a retrospective analysis was performed to investigate the effect of selective dry cow treatment on mastitis incidence measured by mastitis injectors sold in practice. Also the effect on several udder health parameters was analyzed.

Materials and Methods: For the retrospective analysis three periods were compared. The three periods are September 2012 to Sept 2013 (period 1), Sept 2013 to Sept 2014 (period 2) and Sept 2014 to Sept 2015 (period 3). For each period the following parameters were calculated on farms using selective dry cow treatment:

1. Total number of dry cow antibiotic injectors and internal teat sealers sold
2. Total number of mastitis injectors sold
3. Average Bulk milk somatic cell count in September for farmers (n=31) participating in specific management program (Pir Dap)
4. Average cow somatic cell count of culled cows in the management program (Pir Dap)
5. Culling percentage of farms in the management program (Pir Dap)

Selective dry cow treatment means only antibiotic dry cow treatment of cows with a cell count over 50.000 and heifers over 150.000 cells/ml.

The results of the last three parameters are compared to the data of farms not using selective dry cow treatment in the same period. Farms not using selective dry cow treatment are using dry cow antibiotics on every cow entering the dry period.

The first two parameters are available from the practice management system. The last three parameters from farms participating in a specific farm management program, called Pir Dap in The Netherlands. This data is also available for veterinarians with permission from the farmer.

Results: During the 3 year period a gradual decrease up to 10% in the number of dry cow antibiotic injectors sold was observed. Also a decrease of 14% was seen in the number of mastitis injectors sold. An increase of 27% in the number of teat sealers was noticed, but was less obvious in period 3. The evaluation of the bulk milk somatic cell count of 31 farmers participating in the Pir Dap management program showed an increase on 12 farms (39%), a decrease on 12 farms (39%) and on 7 farms (22%) the BMSCC remained stable. Half of the farms showed an increase of the average cow somatic cell count of culled cows and the other half a decrease. The culling percentage of 21 farms was analyzed and was on 11 farms reduced, increased on 7 farms and remained the same on 3 farms during the 3 year period.

The analysis of farms not using selective dry cow treatment (n=6) showed that BMSCC showed the same trend as farms using selective dry cow treatment (2 increased, 2 decreased, 2 remained the same), less farms had an increased cow SCC of culled cows (17% versus 48%) and more farms had a reduced culling percentage (67% versus 52%), compared to the farms using selective dry cow treatment. Additional evaluation of udder health parameters on farms using selective dry cow treatment will be performed.

Conclusions: By the number of dry cow and mastitis injectors sold we could conclude that selective dry cow treatment does not have a negative impact on mastitis. It is difficult to draw conclusions from the culling percentage since 2 factors played an import role. Due to the end

of the quorum system in 2014 less cows were culled. And in 2015 more cows were sold due to the low milk price.

We can conclude that farmers not using selective dry cow treatment seem to have a lower cow SCC at culling and a reduced culling percentage.

A Diagnostic Tool for the Detection and Quantification of Pathogenic Bacteria in bovine milk samples from dairy farms in Bangladesh

Michal Pochodyla ¹ Mohammed Solaiman ²

¹Laboratorios HIPRA, Amer (Girona), Spain, ²NASCO AGRO Products, Chittagong, Bangladesh

Objectives: The aims of the present study were: 1) to show the results obtained from milk samples from Bangladesh dairy farms, using an FTA card and PCR diagnostic tool (STARTCHECK®) provided by HIPRA and 2) to show that STARTCHECK® can be used to complement Somatic Cell Count (SCC) and Bacterial culture to monitor mastitis at a herd level by detecting the major mastitis causative agents (Staphylococcus aureus, Escherichia coli, Coagulase Negative Staphylococci (CNS) and coliform bacteria).

Materials and Methods: A total of 102 Bulk Tank Milk (BTM) samples and Pooled Mastitis Milk (PMM) samples were collected from different dairy farms in Bangladesh, between July and August 2015. The samples were taken by professionals according to the STARTCHECK® instructions [Drawing up 250ul of milk in a sterile manner (gloved hands) from the Bulk Tank (after 5 minutes of stirring) and 250ul of milk from the pooled mastitis cows in separate pipettes, then impregnating the designated areas (BTM and Mastitis Pooled) on the FTA card with the respective milk samples]. The inoculated FTA cards were sent with the farm details (number of lactating cows, average milk production and most recent Bulk Tank somatic cell count [SCC] reading) to DIAGNOS (HIPRA) in Amer, Girona, Spain via courier services. The samples were processed and tested using the Real- Time Multiplex PCR assay, to detect the presence of genetic material for S aureus, E. coli, Coagulase Negative Staphylococci (CNS) and coliform bacteria. The results were determined as positive or negative based on the Cycle threshold (Ct) values, with Ct values below 37 being considered as positive. The positive results were reported in a semi- quantitative manner, indicating the amount of genetic material obtained from each bacteria in the samples.

Results: All samples (100%) were positive for at least one bacteria. The prevalence of each pathogen from the Bangladesh data is as follows: Staphylococcus aureus, Escherichia coli, Coagulase Negative Staphylococci (CNS) and coliform bacteria were detected in 33%, 93%, 99% and 35% of samples respectively. Of these 102 samples 51 were BTM samples and 51 were PMM samples. The prevalence of each pathogen in its respective sample type is as follows: Staph aureus (27% and 39%), E. coli (88% and 89%), CNS (98% and 100%) and coliform bacteria (94% and 98%).

Conclusions: Mastitis is a multi- aetiological condition and needs to be managed with a multifactorial approach (good management and vaccination). STARTCHECK® has been used worldwide since 2009 and milk samples from 47 different countries have been analysed. STARTCHECK® is a good diagnostic and surveillance tool to identify pathogenic bacteria present at a herd level using BTM and PMM samples. The high specificity and sensitivity circumvents limitations

experienced with bacteriology (transport or poor growth) and the human error with individual cow SCC cut off level of 200 000 cells/ ml.

Acknowledgements: We would like to thank Diagnos group, who analysed all the samples.

The resistance to antibiotics and production of enterotoxins in coagulase negative staphylococci isolated from clinical mastitis in dairy cows

Milan Vasil ^{1*}Juraj Elecko ¹Frantisek Zigo ¹Zuzana Farkasova ¹

¹Department of animal husbandry, University of veterinary medicine and pharmacy, Košice, Slovakia

Objectives: In recent decades, especially coagulase-negative staphylococci (CoNS) were diagnosed as ruminant mastitis agents in many countries, with significant impact on the economy of milk production. The aim of the work was the determination of the resistance to antibiotics and finding capacity to produce enterotoxins in coagulase negative staphylococci isolated from clinical mastitis in dairy cattle breeding.

Materials and Methods: During the two-year experiment in holding of 120 Slovak spotted cattle in Eastern Slovakia was udders of dairy cows examined clinically and bacteriologically a total of six times and each time the milk sample examined by NK-test (CMT). For the diagnosis of staphylococci was used set STAPHYtest 24 and evaluated by program TNW, version 7.0 ProAuto (Erba Lachema, Brno, CR). All isolated pathogenic bacteria CoNS (n = 41) from clinical mastitis were in vitro tested on Mueller-Hinton agar by zone disc methods (EUCAST, 2014) on resistance to 14 antibiotics: Ampicilin (10 µg); Amoxicilin (25 µg); Cloxacilin (5 µg); Cefoxitin (30 µg); Erytromycin (10 µg); Linkomycin (15 µg); Neomycin (10 µg); Novobiocin (5 µg); Penicillin (10 U); Streptomycin (10 µg); Ampicilin/Sulbactam (10µg); Oxacilin (5 µg); Cephalotin (30 µg); Tetracyklin (10 µg) (OXOID Ltd. Basingstoke, Hants, UK). Bacteria were rated as resistant or sensitive according reference zone by manual from producer. Identified bacteria CoNS were examined also on presence of genes coding their enterotoxigenic activity (sea, seb, sec, sed, see) by PCR method according to (Becker et al. 1998). Every strain with confirmed gene was examined for production of enterotoxins by Ridascreen ® Set A, B, C, D, E (R-Biopharm AG, Darmstadt, Germany).

Results: From a total of 732 individual milk samples, 218 positive accounted for 29.8%. From clinical mastitis cases were 7.9% (58) determined as the positive. Up to 5.6% (41) in cases of clinical mastitis bacteria were caused by CoNS. It was identified in 7 species *S. epidermidis* (13), *S. warneri* (9), *S. chromogenes* (7), *S. xylosus* (5), *S. sciuri* (3), *S. lentus* and *S. cohnii* (2). The bacteria in total caused 70.7% of clinical cases, which require antibiotic treatment. Highest value of antibiotic resistance bacterium CoNS isolated from clinical mastitis were determined to penicillin (15/41) and novobiocin (13/41). The presence of genes coding production of enterotoxins in bacteria coagulase negative staphylococci (n = 41) was as follows - tree strains of *S. epidermidis* showed presence of gene sea (1), and sec (2), but by ELISA method was confirmed only production SE types A (1) and C (1) in two strains; in *S. chromogenes* and *S. warneri* was determined presence of one gene sec, but only in *S. chromogenes* was conjugated with production correspondent type of SEC; in *S. xylosus* was found gene sed. Was confirmed the presence of the gene (seg) encoding

staphylococcal enterotoxins (SE) in 4 (9.7%) cases, in vitro production of SE was observed in 3 (7.3%) cases.

Conclusions: Tested coagulase negative staphylococci from 41 clinical mastitis cases showed high resistance to penicillin, especially for bacteria *S. epidermidis* (5/13), *S. chromogenes* (3/7), *S. xylosus* (2/5) and novobiocin, especially for bacteria *S. epidermidis* (6/13), *S. warneri* (3/9), *S. chromogenes* (3/7). In bacteria *S. epidermidis* (3), *S. chromogenes* (1), *S. warneri* (1), *S. xylosus* (1) were by PCR detected the presence of genes sec (4), sea (1) and sed (1), but production of SE by ELISA method only in *S. epidermidis* SEA (1) and SEC (2) in *S. epidermidis* and *S. chromogenes*.

RAPD analysis of genome diversity and detection of virulence-associated genes in Staphylococcus aureus isolated from bovine mastitis

Limei Zhang ^{1*}Yan Li ¹Shiyao Zhang ¹Bo Han ¹

¹China Agricultural University, Beijing, China

Objectives: Staphylococcus aureus is recognized as a pathogen causing many serious diseases in humans and animals and is one of the most common etiological agents of clinical and subclinical bovine mastitis. The purpose of this study was to investigate the genome diversity of *S. aureus* strains (n=46) isolated from bovine mastitis in Beijing, Hebei and Liaoning by RAPD(randomly amplified polymorphic DNA) and to determine the presence of genes encoding fnbA, fnbB, hla, hlb, pvl, etA, etB and tst by PCR (polymerase chain reaction amplification).

Materials and Methods: A random primer: 5'-TGACCCGC-3' was used to amplify the genome DNA of Staphylococcus aureus, and then the amplification products were separated by gel electrophoresis and photographed under UV light. The RAPD profiles were compared on the basis of the presence or absence of each DNA band, and strain diversity was calculated using the Jaccard's coefficient and UPGMA (unweighted pairgroup arithmetic average clustering) cluster analysis. In addition, primers for the virulence-associated gene were designed using DNAMAN, respectively

Results: RAPD results showed that all the *S. aureus* isolates produced 2-7 different banding patterns and were divided into 10 genotypes at the identity level of 55%. A significant variation of genotypes was found in different areas like that genotype I and II in Beijing, genotype VIII and IX in Hebei and genotype III in Liaoning province. In addition, all isolates were found to harbor one or more virulence-associated genes, and the most frequently encountered genes were hla(100%), hlb(100%) and tst(100%), followed by fnbA(70%), fnbB(33%), etA(24%), pvl(4%) and etB(2%), respectively.

Conclusions: The diversity of *S. aureus* genotypes in areas of Beijing, Hebei and Liaoning provinces indicated that environmental conditions may be an important factor Furthermore, the relatively wide distribution of the genes hla, hlb and tst suggested that they play a prominent role in bovine mastitis pathogenesis. The present study provides a valuable insight into the genotype and virulence associated genes of this important pathogen.

Comments: The present study provides a valuable insight into the

genotype and virulence associated genes of *Staphylococcus aureus* isolated from bovine mastitis. This research was supported by No.2012bad12b03, No.313054, No.20120008110042 and No.31572587

Sequence Analysis Of Coagulase Genes Of *Staphylococcus Aureus* Isolated From Mastitis

Abid Hussain¹Mansuruddin Ahmad², Muhammad H. Mushtaq²

¹Epidemiology and Public Health, University of veterinary and animal sciences,, ²Epidemiology and Public Health, University of veterinary and animal sciences, lahore, Pakistan

Objectives: Mastitis is a major dairy herd problem mainly caused by *Staphylococcus aureus*. The present study was conducted to determine the relationship of coagulase gene of *Staphylococcus aureus* between Pakistani and other world strains.

Materials and Methods: The milk samples were collected from mastitic buffaloes. DNA extraction was performed as prescribed by Genomic DNA Purification Kit. DNA amplification was carried in thermocycler (Kyratec SC 200) with following cyclic conditions: Initial denaturation at 95 °C for 5 min followed by 30 cycles of denaturation at 94 °C for 30 sec, annealing at 52 °C for 30 sec for Coagulase gene. Then extension at 72 °C for 30 sec. A final extension at 72 °C was carried out for 5 min. All the PCR products were run on 1.2 % agarose gel stained with ethidium bromide and visualized under UV light in Gel Documentation System (BioRad USA). The isolated strains were subjected to sequence analysis of coa gene and phylogenetic tree (using MEGA6.1 software package) was constructed.

Results: It revealed that the coa gene of *S. aureus* strains, isolated from mastitic buffalo milk samples, could be grouped in two clades which were closely related to *S. aureus* isolates from Japan, India and Taiwan, while *S. aureus* isolates from Germany, UK and USA were distantly related. These results indicated the genetic relatedness of Pakistani isolates with other reported isolates from different parts of the world. All the Pakistani strains of coagulase gene were 99.98-100% similar while their divergence was 0.02%. The Japanizes strains were close to Pakistan strains and their similarity and divergence was 99.97% and 0.03%, respectively. The Pakistani strains were 99.93% similar and 0.07% divergent from Indian and German strains. Similarly, the Pakistani strains were 99.94% similar and 0.06% were divergent from UK and Taiwan reported strains.

Conclusions: This particular knowledge may support in effective diagnosis, treatment and control of mastitis in river buffaloes in Pakistan. These findings will also be helpful in future for designing suitable mastitis control strategies in the country.

A Diagnostic Tool For The Detection Of Bacteria (*Staph Aureus*, *E.Coli*, Cns And Coliforms) In Bovine Milk Samples From Dairy Farms In South Africa

Grant Van Lelyveld¹, Daniel Zalduendo Franco², Laura Valls Vila³

¹Technical and Marketing Manager, Ruminants, HIPRA, Southern Africa, Pretoria, South Africa, ²Corporate Group Manager Ruminants

Business Unit, ³Coordinator Diagnos, Laboratorios HIPRA, S.A., Amer (Girona) , Spain

Objectives: The aims of the present study were: 1) to show the results obtained from milk samples from South African dairy farms over the past three years, using an FTA card and PCR diagnostic tool (STARTCHECK®) provided by HIPRA and 2) to show that STARTCHECK® can be used to complement Somatic Cell Count (SCC) and Bacterial culture to monitor mastitis at a herd level by detecting the major mastitis causative agents [*Staphylococcus aureus*, *Escherichia coli*, Coagulase Negative *Staphylococci* (CNS) and coliforms].

Materials and Methods: A total of 301 samples [151 Bulk Tank Milk (BTM) samples and 150 Pooled Mastitis Milk (PMM) samples] were collected from different dairy farms in South Africa, between January 2012 and February 2015. The samples were taken by veterinarians according to the STARTCHECK® instructions [Drawing up 250ul of milk in a sterile manner (gloved hands) from the Bulk Tank (after 5 minutes of stirring) and 250ul of milk from the pooled mastitis cows in separate pipettes, then impregnating the designated areas (BTM and PMM) on the FTA card with the respective milk samples.]. The inoculated FTA cards were sent with the farm details (number of lactating cows, average milk production and most recent Bulk Tank SCC reading) to DIAGNOS (HIPRA) in Amer, Girona, Spain via ordinary post or courier services. The samples were processed and tested using the Real-Time Multiplex PCR assay, to detect the presence of genetic material for *Staph. aureus*, *E. coli*, CNS and Coliform bacteria. The results were determined as positive or negative based on the Cycle threshold (Ct) values, with Ct values below 37 being considered as positive. The positive results are semi-quantitative indicating the amount of genetic material obtained from the samples correlating to the prevalence of the pathogen in the herd taking into account dilution factors.

Results: A total of 266 samples (96,3%) were positive for at least one bacteria (*Staph aureus*, *E. coli*, CNS and Coliforms), while 3,7% of the samples tested were negative for all four pathogens. Of these 266 samples, 144 were BTM samples and 166 were PMM samples. The prevalence of each pathogen in its respective sample type (BTM and PMM) is as follows: *Staph aureus* (19,4% and 32%), *E. coli* (59,7% and 73,7%), CNS (96,5% and 94,3%) and Coliforms (30,5% and 44,2%). The prevalence of each pathogen from the South African data is as follows: *Staph aureus* 26%, *E. coli* 66%, CNS 96% and Coliforms 38%.

Conclusions: Mastitis is a multi-aetiological condition that needs to be managed with a multifactorial approach. STARTCHECK® has been used worldwide since 2009 analysing samples from 44 different countries. STARTCHECK® is a good diagnostic/surveillance tool that can identify bacteria at a herd level using BTM samples. The high specificity and sensitivity circumvents limitations seen with bacteriology and SCC cut off levels of 200 000 cells/ml. STARTCHECK® has semi-quantitative properties. Compared with worldwide data, the presence of *Staph. aureus* in South African samples (26%) is higher than samples obtained from other countries (6-10%).

A Controlled Field Study Investigating The Effects Of A Mastitis Vaccine In A *Staphylococcus Aureus* Positive Dairy Herd

Inge-Marie Petzer¹, Joanne Karzis¹

¹Production Animal studies, University of Pretoria, Onderstepoort, Pretoria, 0110, South Africa

Objectives: Despite improvements in management, *S. aureus* remains a major cause of mastitis. Its chronic and destructive nature often leads to premature culling and ample loss of revenue. Additional help was sought in the form of a mastitis vaccine to overcome this challenge. The study investigated the ability of a mastitis vaccine to reduce new intramammary infections (IMI) with *Staphylococcus aureus* (*S. aureus*), improve bacterial cure, and reduce the duration of IMI and to investigate its effect on milk somatic cell count.

Materials and Methods: A total of 164 multi- and primiparous cows from a herd with 251 lactating cows with a 16.51% herd prevalence of *S. aureus* were enrolled into this controlled study. The selection of the treatment and control cow groups were based on the principle of matching. Cows were matched according to their parity, milk yield, *S. aureus* intramammary infections and the number of quarters infected per udder, the level of somatic cell counts and the udder parenchyma status based on results from udder palpation. Half of the remaining lactating cows in the herd not selected were also vaccinated to allow for an even exposure of vaccinated and control cows in an attempt to limit the effect of partial protection or exposure of herd mates. Selected cows were vaccinated on days 0, 35 and 87 of the study and quarter milk samples were collected at day 0 and monthly thereafter for 5 consecutive months for micro-cytology analysis. The Startvac (Hipra Southern Africa) mastitis vaccine was used. It contains an inactivated *S. aureus* (CPS) SP140 strain expressing Slime Associated Antigenic Complex (SAAC) and an inactivated *Escherichia coli* (J5). The generalized linear mixed model (GLMM) was used to evaluate somatic cell counts and milk yield over time was analysed using a linear mixed model for repeated measurements. Mean values were separated using Fisher's protected least significant difference test (FPLSD) and the Studentized range at the 5% level.

Results: This study demonstrated a significant ($P < 0.001$) increase of new *S. aureus* IMI in control cows while numerically fewer quarters were newly infected in the vaccine groups (0.88% to 2.56%). The duration of the quarter infections in the vaccine groups was 26.3% shorter (4.3 to 3.6 samplings months) than those in the control group. The combination of the reduced duration and fewer new infections in vaccinated animals contributed in reducing the overall exposure of cows within a herd to *S. aureus* IMI. This was evident in the significantly ($P < 0.05$) higher numbers of *S. aureus* isolated from the control group during the study.

The number of *S. aureus* clinical flare ups present in the vaccine group was significantly ($P < 0.05$) less and their cure rate higher although not significantly (44.23% compared to 34.55% in the control group). Significant ($P < 0.001$) differences in the SCC were found between sample periods but not between groups. Somatic cell count was 9.68% lower in the vaccine group regardless of udder infection status. A non-significant daily average gain in milk yield of 0.73 kg was evident in the vaccine group for the six months study period.

Conclusions: We found the overall effect of the vaccine to be moderate with significant and often marginal improvement evident in the vaccine group. Improved cure rate alongside a shorter duration of intramammary infections lower the transmission rate of the bacteria in the herd and indirectly reduced the overall exposure of individuals to *S. aureus*. Less udder parenchyma damage may lead to a perceived increased longevity of animals. To effectively exploit the advances acquired from use of the vaccine and to lower the reproductive ratio of *S. aureus* in a herd, the vaccine should always be used in combination with excellent parlour management and hygiene.

Udder Health & Milk Quality

P04-004-212

A model approach to estimate *Staphylococcus aureus* intramammary infection dynamics for different scenarios when vaccinating for mastitis

Inge-Marie Petzer¹, Joanne Karzis¹, Eric Etter²

¹Production Animal Studies, University of Pretoria, Onderstepoort, Pretoria, 0110, South Africa, ²Research and Development for Agriculture, CIRAD, Montpellier, France

Objectives: When new remedies or treatments are considered for used in a farming enterprise the main concern is whether the benefit will outweigh the cost. Benefits however should not only be measured in economic terms. In addition to stochastic partial budget models that estimate cost and benefits when using Startvac (Hipra) mastitis vaccine, a model was developed to calculate the intramammary infection (IMI) dynamics of *Staphylococcus aureus* (*S. aureus*) at end points. The transmission rate of *S. aureus* depends on various factors, but parlour management and pathogenicity of bacteria are prominent.

Materials and Methods: The reasoning that subclinical *S. aureus* IMI either advanced to clinical mastitis, cure spontaneously or persist was exploited. It was anticipated that the percentage of persistence, cure and clinical cases would differ between old and new *S. aureus* IMI. The transmission parameter (β) used in low and high risk scenarios and varied from 0.0028 to 0.046 new infections daily. The duration of a persistent *S. aureus* IMI was taken as 115 days when few interventions took place. This duration was shown to decrease to 51 days in low somatic cell count herds, when an aggressive approach to detect and to treat subclinical *S. aureus* cases were in place. According to research the basic reproduction ratio (R_0) of *S. aureus* IMI was reduced by approximately 45% with the use of Startvac mastitis vaccine in a herd.

Four different scenarios, all with a *S. aureus* IMI herd prevalence of 15% were explored. The different β for *S. aureus* were combined with and without treatment of subclinical *S. aureus* cases. In all four scenarios vaccinated and nonvaccinated herds were compared.

The model explored two scenarios in herds with a low transmission risk: {scenario A} with an estimated persistent *S. aureus* infection of 115 days {scenario B} and an estimated persistent *S. aureus* infection of 51 days. In addition IMI dynamics were calculated in herds with a high transmission risk: {scenario C} without treatment of subclinical cases and an estimated persistent *S. aureus* IMI across cows of 115 days and {scenario D} with aggressive treatment and an estimated persistent *S. aureus* infection of 51 days.

Results: In scenario A it was estimated at day 153, that 3.37 clinical cases had occurred and 0.01 *S. aureus* cases persisted in the non-vaccinated group compared to 3.13 clinical cases no persistent cases in the vaccinated group. In a non-vaccinated herd during scenario C after 51 and 204 days the persistent *S. aureus* cases increased from 17.02 to 28.19 and clinical cases from 7.50 to 39.15 compared to a reduction in persistent cases from 9.36 to 1.42 and a smaller rise in clinical cases from 5.4 to 13.04 cases when vaccinated. The differences in persistence and clinical cases between non- and vaccinated groups in Scenario D were estimated at day 255 to be 54.60 and 81.20 compared to 16.52 and 30.96 respectively. Results indicated that the longer this mastitis vaccine was used the more distinct its benefits became. During a low risk scenario when vaccination was used in combination with treatment of subclinical *S. aureus* cases, *S. aureus* IMI was eradicated an estimated 51 days earlier than when treatment was used by itself. More pronounced effects were also detected in all high risk scenarios. Persistent *S. aureus* IMI continue to increase in high risk scenarios where subclinical *S. aureus*

cases were only treated but decreased under the same conditions when treatment was combined with vaccination.

Conclusions: The model revealed that the use of this mastitis vaccine provided additional benefits to combat *S. aureus* IMI in both high and low transmission risk scenarios. Less clinical cases occurred from the first cycles and intensified with duration. The only high transmission risk scenario, where persistent and clinical cases were reduced over time was when treatment of subclinical cases was used in combination with the mastitis vaccination.

Models such as this have practical applications and can assist both veterinarians and producers in optimizing predicted cost, benefits and can including the IMI dynamics of *S. aureus* into in their future planning.

P04-004-213

An evaluation of the efficacy of *Staphylococcus aureus* vaccination for the management of mastitis in New Zealand dairy cows

Mark Bryan¹, Shen-Yan Hea², Elena Knupfer³, Michal Pochodyla⁴, Daniel Zalduendo⁴

¹Head of R&D, ²Epidemiologist, VetSouth Ltd, Southland, ³VetSouth Ltd, Winton, New Zealand, ⁴Hipra SA, Barcelona, Spain

Objectives: The objective of this study was to investigate the role of Startvac® vaccination for the management of mastitis in New Zealand dairy cows under field conditions. The study enrolled 15 farms across 3 main dairy regions in New Zealand.

The demonstration of vaccine efficacy in a clinical field trial can be challenging as vaccination may affect the basic reproductive number (R_0) for the infectious organism within the herd. This study was designed at the herd level to mitigate that effect.

Materials and Methods: A total of 15 farms across 3 main dairy regions in New Zealand were enrolled into the study. This consisted of 902 cows from 3 farms in Taranaki, 2427 cows from 4 farms in Canterbury, and 5451 cows from 8 farms in Southland. A total of 3581 cows from 7 farms were vaccinated with Startvac®, 2302 animals from 4 farms were vaccinated with a placebo solution (sterile saline), and 2897 animals from 4 farms were left unvaccinated.

Individual somatic cell counts (ISCC) reflecting intra-mammary infections (IMI) were used to assess the longitudinal effect of Startvac® vaccination within herds. The differences in daily herd somatic cell counts (BMSSC), somatic cell count linear scores (SCCLS), and the proportion of animals with clinical mastitis (CM) were calculated between seasons and compared between treatment groups.

A cut off value of 200,000 cells/ml was used to calculate the proportion of cows with mastitis, and the proportion of uninfected, new, recovered, chronic and repeat infections between two subsequent herd tests. For Southland farms, milk samples were collected by the farmers and cultured to determine the bacteriological status.

Herd test data, bulk tank somatic cell counts and mastitis data were obtained electronically using Infovot and MINDA. MS Excel, MS Access and R were used for database management and data analysis. The treatment effects were estimated by comparing the means of the between season differences (pre and post vaccination) for each farm and treatment group.

Results: The proportion of intramammary infections (ISCC >200,000 cells/ml) at each herd test ranged from 9.3% to 31.0% for 2013-2014 and 9.8% to 26.8% for 2014-2015. The herd level between-season differences in IMI proportion ranged from -21.1% to 6.4%.

A between season reduction in intramammary infections of 3.2% was observed in vaccinated group, whereas the control and placebo control herds experienced an increase of 0.8% and 1.3%, respectively.

The proportion of uninfected animals increased in the vaccinated group (4.8%) and decreased in the control and placebo control farms (-2.5%; -0.7%).

The proportion of new infections reduced in vaccinated farms (-2.1%), reduced slightly in placebo farms (-0.4%) and increased in control farms (1.5%).

The proportion of chronic infections reduced in vaccinated farms (-2.2%) but increased in control and placebo farms (0.4%; 1.6%).

The proportion of repeat infections decreased in all farms (-0.2%, -1.0% and -0.8% for vaccinated, control and placebo respectively).

When compared with the control group, vaccinated herds experienced an average between season reduction of 29.53 (000's) cell/mL, and the placebo control group experienced an increase of 35.16 (000's) cells/mL.

A mastitis incidence risk of 10.9% was calculated for vaccinated herds, whereas control and placebo control herds averaged 8.6% and 8.9% respectively. The increase observed in the vaccinated group was attributed to a single farm experiencing a spring *Streptococcus uberis* outbreak.

Conclusions: The results of this study suggest that StartVac® vaccination may have a positive effect on udder health and could be a useful tool for the management of mastitis under New Zealand field conditions. Furthermore, the results of this study suggest that the placebo effect of trial participation may have an effect on the outcome. Future large scale studies will be beneficial for our understanding of both the herd level response to vaccination, and to better understand the placebo effect of trial participation.

Colonization of *Staphylococcus aureus* in the mucosal inflammatory area in the case of severe clinical bovine mastitis

Yuya Nagasawa¹, Yoshio Kiku¹, Yoshikazu Koyama², Tomonori Nochi³, Hisashi Aso³, Tomohito Hayashi¹

¹Hokkaido Research Station, National Institute of Animal Health, National Agriculture and Food Research Organization, ²Hokkai-Gakuen University, Sapporo, ³Cellular Biology Laboratory, Graduate School of Agricultural Science, Tohoku University, Sendai, Japan

Objectives: *Staphylococcus aureus* causes intractable bovine mastitis and is the one of the most significant mastitis-related problems for dairy farms. Colonization of *S. aureus* in mammary epithelial cells or cell lines, which stem from the lobule with alveoli (LA), has been detected via in vitro situations. Because limited information is available regarding local colonization of *S. aureus* in intramammary infection in udders with bovine mastitis, we established a clinical mastitis model in cows by experimentally infecting with *S.*

aureus to detect the colonization of *S. aureus* via in vivo observation in mammary tissues.

Materials and Methods: To detect colonies of *S. aureus* in the udder, we established 5 bovine mastitis models using experimental infection with *S. aureus*. Clinical symptoms were recorded twice a day, at the morning and evening milking, for 1 week. Clinical scoring criteria were used to determine the severity of clinical mastitis, utilizing basically the same format previously described (2009, Vet Microbiol. Atalla, et al). Milk was bacteriologically analyzed, and the somatic cell counts (SCC) of the milk was determined. Tissue samples collected from the LA, gland cistern (GC), and teat cistern (TC) were fixed in 10% phosphate-buffered formalin and embedded in paraffin for histochemical analysis. In addition, to clarify whether hematoxylin aggregation represented *S. aureus* colonies, we compared hematoxylin aggregation, gram-positive cells, and *S. aureus* positive cells stained with immunofluorescence using serial sections.

Results: During the 1-week observation period, the milk from all of the udders infused with *S. aureus* had increased SCC and numbers of *S. aureus*; these cows also exhibited clinical symptoms. Based on a scoring system for mastitis severity, 2 cows were classified with moderate mastitis, and 3 cows were classified with severe mastitis. The histochemical analysis showed that a mucosal inflammatory reaction (i.e., broken epithelium and dampness of neutrophils) was present in the entire udder, including not only the LA but also the GC and TC. In addition, aggregation of hematoxylin, gram-positive cells, and *S. aureus* positive cells was localized in the same areas on the mucosal inflammatory areas in severe clinical mastitis. Therefore, with intractable mastitis caused by *S. aureus*, the bacteria could potentially easily colonize various locations of the udder such as the LA, GC, and TC.

Conclusions: Our results demonstrate that mastitis caused by *S. aureus* was reflected in mucosal inflammation of all of the mammary tissue including the LA, GC, and TC, at least in udders infected with *S. aureus*. Furthermore, *S. aureus* colonized near the broken mucosal barrier in severe clinical mastitis. These findings provide information for the mechanism, prevention, diagnosis, and therapy of mastitis caused by *S. aureus* infection.

DETERMINATION OF THE MILK QUALITY BOVINE PRODUCED IN THE MUNICIPALITY OF TARIMBARO MICHOACAN

Carlos Bedolla ^{1,*}Rodolfo Lucio ¹Victor Manuel Sánchez ¹Hugo Castañeda ²Valente Velázquez ³Edith García ¹José Carlos Bedolla ¹

¹Animal Production, University Michoacana of San Nicholas of Hidalgo, Morelia, Michoacán, ²Bovine Mastitis Laboratory, University of Guadalajara, Guadalajara, ³Health Animal, University Autonomous of State of Mexico, Toluca, Mexico, Mexico

Objectives: The aim of this study was to determine the milk quality of bovine produced in the municipality of Tarimbaro Michoacan, through California test, Lactoscan and Microbiological Control.

Determine the percentage of butterfat, protein, and colony forming units/ml in milk samples obtained Tarimbaro municipality, Michoacan.

Materials and Methods: The study was conducted from september of 2012 to may of 2013 in the municipality of Tarimbaro, Michoacan. 100 dairy herds of the same number of production units of municipality

Tarimbaro, Michoacan during the morning milking were sampled. To do this, a milk sample pot of receipt of each herd, previously mixed with a tablespoon placing the sample in a plastic pallet for California test was taken. Then the other part of the sample is poured into a glass jar previously sterilized. Subsequently, we proceeded to place samples in a sealed cooler at a temperature of 4 °C for transport immediately bacteriology laboratory of the Faculty of Veterinary Medicine University Michoacana of San Nicholas of Hidalgo for processing. Samples were analyzed by casting technique plate, both for coliform and for mesophilic aerobic bacteria (BMA).

Results: It was found that 94% of the samples were negative, and 6% grade traces with CMT, that is of excellent quality according to international standards. Regarding the determination of butterfat in gL with Lactoscan analyzer based on the NM-F700-COFOCALEC 2004 standard, it was found that 69% of the samples corresponded to class A, 5% to class B, 6% to class C, while the remaining milk (20%) was found outside the norm. As for the results of bacteriological analysis for BMA, these are also interpreted according to the NM COFOCALEC F-700, (2004), found that 46% of the samples corresponded to class 1, 100,000 CFU/ml, 11% to Class 2, 12% in Class 3, 7% to the Class 4, while the rest (24%) containing It was found that 94% of the samples were negative, and 6% grade traces with test of California, that is of excellent quality according to international standards. Regarding the determination of butterfat in gL with Lactoscan analyzer based on the NM-F700-COFOCALEC 2004 standard, it was found that 69% of the samples corresponded to class A, 5% to class B, 6% to class C, while the remaining milk (20%) was found outside the norm. As for the results of bacteriological analysis for BMA, these are also interpreted according to the NM COFOCALEC F-700, (2004), found that 46% of the samples corresponded to class 1, 100,000 CFU/ml, 11% to Class 2, 12% in Class 3, 7% to the Class 4, while the rest (24%) containing more than 1,200,000 CFU/ml, were classified outside the provisions of this standard. more than 1,200,000 CFU/ml, were classified outside the provisions of this standard.

Conclusions: It is concluded that the milk produced in the municipality of Tarimbaro, Michoacan is good quality, and to comply with the parameters established nationally and internationally. Making it suitable for consumption by the public consumer without risk.

P04-004-216

Best practice approach of Streptococcus agalactiae infection on a dairy farm

Ton Pijs ^{1,*}

¹Dierenkliniek Hellendoorn-Nijverdal, Hellendoorn, Netherlands

Objectives: Our objective was to set up a best practice approach of Streptococcus agalactiae (SAG) infection on a dairy farm. SAG is known to be very contagious on a dairy farm and can cause high cow somatic cell counts (SCC). Often a whole or part herd treatment is applied when SAG infection on a farm is diagnosed. In this case-study, diagnostic testing and treatment decisions on the individual cow level was used as a strategy in order to avoid spread of the pathogens and to use as less antibiotics as possible.

Materials and Methods: On the farm were this strategy was performed, the dairy cows were housed in a free stall barn build in 2011 with a capacity of 450 cows, inclusive dry cows. The barn had closed floors, straw with lime and water added was used as bedding material. The

cows were milked three times daily. At drying off all cows were treated with a small spectrum dry cow antibiotic injector containing cloxacillin and a teat sealer. Although *Staphylococcus aureus* (SAU) was the major pathogen present in the bulk milk samples on this farm, additional SAG infection on the farm was suspected after isolation of the pathogen in a bulk milk sample. At the time SAG was diagnosed the bulk milk somatic cell count (BMSCC) was 293.000 cells/ml.

Initially only cows with new elevated (> 250.000) SCC were sampled for bacteriological culture, but no SAG was detected. Even though the bulk milk showed SAG again. From all cows (n=325) a composite milk sample was taken.

Results: Most dominant pathogens found were Coagulase Negative Staphylococci (CNS)(n= 36), penicillin resistant SAU (n=28) and penicillin sensitive SAU (n=21). In only 3 cows SAG was found. One SAG cow was culled because it had a mixed infection with SAU and a history of high SCC. The other 2 SAG cows were treated with a second choice intramammary injector and systemically with trimetoprim-sulfa, both cows cured. Besides that a separate milking group with high SCC cows was formed. All the cows with penicillin resistant SAU, penicillin sensitive SAU, CNS and *Serratia* species were housed in this group. This group was milked at the end of milking and cows could not leave this group only when culled or after reduced somatic cell count and a negative culture. Individual treatment decisions for this group were based on SCC history, SCC elevation, days in milk and age. The measurements resulted in disappearance of SAG from the bulk milk. Nevertheless the bulk milk somatic cell count did not decrease. Some SAU infected cows in the separate milking group should have been culled, but due to lack of replacement animals those cows remained in the herd. This is also the reason why the number of new infections dropped at first (4%), but increased again after a few months (11%). Twenty to thirty percent of those "new" infections are cows with still a high SCC after the dry cow period (not cured).

Conclusions: Since only 3 cows were found SAG positive we could wonder if SAG is really highly contagious. This particular SAG could have been a more human like and less contagious strain. In this case elevated cow SCC was not a valid criteria for diagnosing SAG infection in cows.

This practice approach led to the treatment of cows that had a good chance to cure only. Therefore minimal antibiotics were needed to tackle the SAG infection in this herd, compared to a more common approach for whole or part herd treatment. Perhaps a more sustainable effect on bulk milk somatic cell count could have been reached if more high SCC and infected cows were culled.

P04-004-217

Biochemical, Microbiological and Cellular Profiles of Crossbred Cow's Milk at Delivery to 180 Days of Lactation

Fernando Casagrande¹, Pricilla Pozzatti², Fabíola O. Paes Leme²

¹Departamento de Anatomia, Patologia e Clínica Veterinárias, Universidade Federal da Bahia, Salvador - BA, ²Departamento de Clínica e Cirurgia Veterinárias, Universidade Federal de Minas Gerais, Belo Horizonte, Brazil

Objectives: This study evaluated the incidence of pathogens, such as Somatic Cells Count, Total Bacterial Count, biochemical evaluation and

differential cell of 225 milk samples from February 2012 to November 2012.

Materials and Methods: Twenty-five crossbred cows, pluriparous, from a commercial farm located in the district of Ibitira, Martinho Campos, Minas Gerais were used. To collect, pre-dipping routinely made by the farm, then cleaning the ceilings with gauze soaked in 70% alcohol was performed. After this procedure the disposal of the first three streams of milk was performed and conducted the store. The collections were made on the exact day of delivery and colostrum, 5, 10, 30, 60, 90, 120, 150 and 180 days thereafter. After milk collection, the slides were prepared and stained for Total Bacterial Count, estimated somatic cell count and differential cell count. The remaining material was used for bacterial isolation and biochemical evaluation.

Results: In somatic cell count, decreased between the third and fourth months of lactation and increased for the middle third lactation was observed. About 48% of the animals evaluated at all times had Somatic Cells Count above 200,000 cells/ml of milk. For the presence of pathogens, of 25 cows, 18 (72%) were positive for *Staphylococcus aureus* in early lactation and only this pathogen was present until the end of the experiment. Cows that have high somatic cell counts also show increased concentration of magnesium chlorides and calcium in the whey. According to the cellularity of milk, this work presented as predominant in milk cells neutrophils, followed by lymphocytes and macrophages and the concentration of chlorides, magnesium, calcium, alkaline phosphatase and GGT in milk, accompanied increasing the concentration of lymphocytes in the same.

Conclusions: The most prevalent pathogens in the course of this study were *Staphylococcus aureus*, *Streptococcus uberis* and *Bacillus* spp. In biochemical evaluation in automatic device, when there was an increased concentration of somatic cells, there was an increase in the concentration of chloride, calcium, magnesium, alkaline phosphatase and gamma- glutamyl transferase in milk. The differential cell performed by optical microscopy, was increased when the concentration of somatic cells, it increased the concentration of neutrophils, lymphocytes, eosinophils, macrophages, epithelial cells and basophils.

An investigation on the efficacy of a vaccine against *Staphylococcus aureus* under field conditions in Northern Italy

Alessandra Angelucci¹, Francesca Fusi¹, Valentina Lorenzi¹, Giorgio Zanardi¹, Luigi Bertocchi¹

¹Reparto Produzione Primaria, Istituto Zooprofilattico Sperimentale della Lombardia e dell'Emilia Romagna "B. Ubertini" (IZSLER), Brescia, Italy

Objectives: The aim of this study was to evaluate the efficacy of a commercial vaccine (Startvac®, Hipra Spain) aimed at reducing intramammary infections (IMI) by *Staphylococcus aureus* and coagulase-negative staphylococci under field conditions.

Materials and Methods: This study was carried out in a farm in Northern Italy, which was selected basing on the size of the herd (450 lactating cows). Cows were randomly allocated in two groups. The first group received the vaccine following the label regime, and the second group was left unvaccinated to act as controls. The two groups were housed in the same pen. Four aspects of vaccine effectiveness were

considered: the first includes the impact of vaccination on the rate of new infections, second it concerns the impact of vaccination on the reduction of shedding of *S. aureus* from an infected animal, third it addresses the impact of vaccination on the rate of cure of the infection; and the finally, the fourth aspect concerns the reduction of clinical symptoms related to infection due to vaccine effectiveness. Vaccination of animals was made according to the registration protocol of the vaccine for a total of three doses, with the first dose at 45 days before the estimated date of calving, the second administration at 10 days before the date of calving, and the third dose at 52 days post-calving.

Results: Results refers to about half of the trial duration (18 months). The prevalence of *S. aureus* in the studied herds was about 3% at single quarter level for vaccinated cows, while the prevalence of coagulase-negative staphylococci amounted to approximately 6%. The incidence of new staphylococcal IMI was lower in the vaccinated group than in the control group. Results showed a moderate difference in *S. aureus* prevalence in milk samples examined between vaccinated and control animals (3% in vaccinated group; 4% in control group). However, the average duration of infection by *S. aureus* was significantly shorter in vaccinated animals compared to control animals. We detected also a lower number of cases of clinical or subclinical mastitis in the vaccinated group than in the control group.

Conclusions: The results indicate that the vaccine can be an effective tool to control staphylococcal mastitis, by reducing the incidence and duration of the infection. As reported in other studies, mastitis vaccination can play an important role in the mastitis control programs (Schukken et al, 2014; Bradley et al, 2015).

Elimination of bacteria in experimentally induced *S. epidermidis* intramammary infection assessed by PCR and plate counting

Heidi Hiitiö¹·Heli Sijojoki¹·Suvi Taponen¹·Satu Pyörälä¹

¹Department of Production Animal Medicine, University of Helsinki, Helsinki, Finland

Objectives: The aim of this study was to follow-up infection and inflammation process in experimental *Staphylococcus epidermidis* intramammary infection (IMI) using milk somatic cell count (SCC) and two bacteriological methods, conventional bacteriological culture (BC) and real-time PCR. Our hypothesis was that IMI would be eliminated faster when assessed with BC than assessed with PCR, as PCR amplifies also DNA of dead or damaged bacteria.

Materials and Methods: One quarter free from bacterial growth and with milk SCC<100,000 of eight primiparous cows was experimentally infected with *S. epidermidis* (PM221). The inoculum contained 5.7 × 10⁶cfu in 7 ml of saline. Aseptic milk samples were collected at -24h and 0h before the challenge and then at 4, 6, 12, 21, 27, 30, 36, 45, 54, 69, 78, 93, 102,117, 126, 141, 168, 240 and 336h post-challenge (PC). 100 µl and serial dilutions of each sample were cultured on blood agar for bacterial counting. Detection limit for a positive result was 10 cfu/ml of milk. Colonies were identified as CNS by standard procedures. Samples were also tested with real-time PCR (PathoProofTM Mastitis Complete-12 Kit, Thermo Fisher Scientific Ltd, Finland). Cycle threshold (Ct) values were measured up to 40.0. Ct cut-off limit for a positive result was 37.0. Milk SCC was determined with Fossomatic (Valio Ltd, laboratories Finland).

Results: All quarters became infected with *S. epidermidis*. For all cows mean bacterial counts of the two-week period were 1.93 log₁₀ cfu/ml (SD 1.49), mean Ct value was 31.17 (SD 4.15) and SCC 2.865,174 cell/ml (SD 3.668,413). According to both diagnostic methods, the amount of *S. epidermidis* was the highest at the second sampling 6h PC, when bacterial count was 4.02 log₁₀ cfu/ ml (SE 0.38) and in PCR the mean Ct-value 27.74 (SE 1.46).

Based on BC, 3 out of 8 cows were spontaneously cured within the two week period and five cows remained persistently infected. Infections were eliminated i.e. no bacterial growth was detected after 54h (Cow 1), 240h (Cow 2) and 45h (Cow 6) PC. SCC at these time points were 8 988 000 cells/ml, 517 000 cells/ml and 4 063 000 cells/ml.

Assessed with PCR, only one cow was tested negative at time point 240 h PC (Ct value 40.0, Cow 1). At this point, milk SCC of the quarter was 57 000 cells/ml.

Conclusions: The amount of *S. epidermidis* bacteria was the highest at 6h PC assessed with both diagnostic methods. Within the two-week period, 3/8 quarters were cured according to BC results, but only one with PCR. Quarters defined cured with BC had still high milk SCC, which is not surprising as inflammation disappears slower than infection. Milk SCC of the quarter defined cured with PCR was low, indicating also resolved inflammation in that quarter. PCR may give positive results for longer than culture, as it amplifies also DNA from dead, damaged and growth-inhibited bacteria. Thus control samples after IMI may be advisable only after decreased SCC.

Bovine *Staphylococcus aureus*: subtyping, evolution and zoonotic transfer

Hans Ulrich Graber¹·Renate Boss²

¹Agroscope, ²Federal Food Safety and Veterinary Office, 3003 Bern, Switzerland

Objectives: *Staphylococcus (S.) aureus* is globally one of the most important pathogens causing mastitis in cattle. Former studies, however, demonstrated in Swiss cows that *S. aureus* isolated from bovine intramammary infection (IMI) is genetically heterogeneous. *S. aureus* genotype B (GTB) is contagious whereas all the remaining genotypes are involved in individual cow disease. The aim of the present study was to compare 3 subtyping methods using strains of *S. aureus* isolated from IMI and bulk tank obtained from various European countries. The phylogeny of animal *S. aureus* was inferred and the zoonotic transfer between cattle and humans was studied.

Materials and Methods: 456 bovine strains of *S. aureus* were examined that were obtained from 12 European countries. The isolates originated from aseptically collected milk samples from single-quarters (SQM) with subclinical IMI, from bulk tank milk (BTM) or from own strain collections (subclinical IMI). The strains were subtyped by ribosomal spacer PCR (RS-PCR; Fournier et al., 2008), spa typing (Harmsen et al., 2003), or multilocus sequence typing (MLST; Enright et al., 2000). Phylogenetic analyses were conducted as described by Kuhn et al. (2006) using whole genome sequences of 30 strains available in public databases (NCBI) or obtained from own bovine strains. The transfer of *S. aureus* between cattle and humans was studied based on the spa types. They resulted from the present study (cattle) or from the study

by Grundmann et al. (2010) who mapped the geographic distribution of dominant types causing invasive human infections in Europe.

Results: All the analyzed strains could be allocated to the 6 genotypes GTB, GTC, GTF, GTI, GTR, and GTOG. Comparing the 3 subtyping methods, RS-PCR showed the highest resolution followed by spa typing and MLST. The associations among the methods were unsatisfactory except for GTB and GTC. *S. aureus* GTB is positive for CC8 (MLST) in 99% of the cases and is typically positive for spa type t2953. *S. aureus* GTB is the cattle-adapted subtype of CC8. *S. aureus* GTC was always positive for t529 and was typically positive for CC705. The link among the 3 methods for GTR and the remaining genotypes was poor. Bovine *S. aureus* is highly clonal and a few clones predominate. Animal *S. aureus* always evolve from human strains whereby every human one may be the ancestor of a novel animal-adapted strain. At least in the case of the bovine genotypes GTB, GTC, GTI, and GTR, the zoonotic transfer of *S. aureus* between cattle and humans is very limited and the different hosts are not considered as a source for mutual, spontaneous infections. Spillover events, however, may happen.

Conclusions: The present study allowed assigning bovine strains to 6 genotypes whereby GTB, GTC, and GTR were the most prominent ones. RS-PCR showed the highest typing resolution followed by spa typing and MLST. *S. aureus* GTB is the cattle-adapted subtype of CC8 and GTC is highly conserved (only 1 spa type was observed). For GTR and the other genotypes, the link among the 3 methods was poor. Bovine *S. aureus* is highly clonal and a few clones predominate. Animal strains of *S. aureus* evolve from human-adapted ones; every human strain may be the ancestor of a novel animal strain. The zoonotic transfer of *S. aureus* between cattle and humans is very limited.

FIELD EXPERIENCE WITH A POLYVALENT MASTITIS VACCINE IN A COMERCIAL DAIRY FARM INFECTED WITH STAPHYLOCOCCUS AUREUS

Demetrio Herrera ^{1*} Oriol Franquesa ¹ Laura Hurtado ¹ and Q-Llet SLP

¹Q-Llet SLP, SEVA, Spain

Objectives: The objective of this poster is to show the efficacy of a mastitis vaccine (STARTVAC⁰) along with management practices to reduce spreading and control *Staphylococcus aureus* in a commercial dairy farm with high prevalence of infection by *S. aureus*

Materials and Methods: The farm is located in Spain milking 600 cows 3 times. Cows in lactation are housed in pens with freestalls bedded with recycled dry manure and environmental conditions are very good, with very low clinical mastitis rate (< 2% monthly). However, the farm has been fighting against *Staph aureus* since 5 years, with high BTSCC and high prevalence of infection. Despite checking the healthy groups by CMT, culturing and segregating *Staph* positive animals many times, and cheking fresh animals after calving by culture, new positive animals appeared after in the healthy group. In July 2014, the farm had problems cleaning and sanitizing the milking machine and we experienced a dramatic outbreak in new cases (64). In February 2015, all the animals in the healthy groups were sampled for PCR twice in a week time difference and we segregated *Staph aureus* positive animals once again. Fresh animals are sampled by PCR one week after calving in the fresh group and positives are segregated. At the same time, we vaccinated all the lactating animals, dry cows and heifers two months before calving

and and revaccinated 21 days. After that, the whole farm has been vaccinated each 3 months. The farm is making monthly SCC test at cow level and we used these data to calculate some key performance indicators related to dynamics of infection, as % of chronic cows, new infection risk, and average linear score

Results: The farm udder health has been improving and only one new case of *Staphylococcus aureus* has appeared since we implemented vaccination and it was in a fresh heifer last August. As a result, BTSCC is decreasing day by day, with less chronic animals (the percentage of chronic cows has been reduced from 27% to 17%), lower new infection risk (the new infection risk is 3% lower on average than in the same period before vaccination) and lower average linear score (the LS has go down from 3,3 to 2,7).

Conclusions: Along with other management practices to control *Staphylococcus aureus*, vaccination in this farm is having a great impact contributing to minimize spreading of *S. aureus* within the herd, improving udder health and reducing Bulk Tank Somatic Cell Count.

Development of real time PCR tools for bovine mastitis etiological diagnosis and herd management

Virginie Flachon ^{1*} Pierre Mathevet ¹ Eric SELLAL ¹ Ivanna LEPELIER ² Eric Le Dréan ³ Guillaume LEQUEUX ³

¹BioSellal, 69007 Lyon, ²GDS Bretagne, Vannes, ³ISAE/Labocea, Javené, France

Objectives: Bovine mastitis causes large economical losses worldwide. Identification of mastitis associated-bacteria is a required step to set up adapted dairy farm management. The use of microbiological cultures and biochemical tests for bacterial identification presents several drawbacks: time-consuming, difficult to automate, false-negative results (due to the presence of bacterial growth inhibitors or residual antibiotics), potential miss-identification and is not adapted to composite milk samples analyses. DNA-based diagnosis ie real-time Polymerase Chain Reaction (qPCR) is the best fit tool to detect and quantify major mastitis causing germs.

Materials and Methods: Based on bacterial prevalence in French dairy farms, qPCR assays (Bio-T[®] milk qPCR line) were developed to detect major and minor mastitis causing bacteria as for example *Staphylococcus aureus*, *Staphylococcus spp*, *Streptococcus uberis*, *Streptococcus dysgalactiae* and *Enterobacteriaceae*.

Each qPCR assay was designed as duplex detecting i) the bacteria of interest and ii) an exogenous internal positive control, moreover a standard positive control was developed to enable targeted bacteria quantification too. Such individual qPCR assay format (1 bacterial target / qPCR) enables a flexible tailor-made approach to screen independently from 1 to 12 bacterial targets, depending on the sample type, geographic area or epidemiological context. This format is adapted to selectively target bacteria of interest and avoid thorough screening of numerous pathogens including minor interest germs.

Results: We first report on the experimental inclusivity-exclusivity data, qPCR limit of detection and qPCR efficiency for each target using both purified DNA (genomic DNA, standard plasmid DNAs), spiked and field milk samples. Then, to complete experimental validation, an epidemiological study was done, comparing somatic cell counts, conventional bacterial identification and qPCR using our in house

designs for 5 targets (major mastitis pathogens). 620 quarter milk and 12 bulk tank milk samples were collected from 12 dairy farms deriving from 4 different French regions (3 herds / zone): about 10-15 cows per herd (almost 20% of the herd) including 1-2 control milk cows. First results showed a good correlation between conventional identification method and qPCR data for 66% of milk samples. Besides, this study indicated that qPCR assays enabled to detect a major mastitis causing pathogen for 20% of milk samples tested negative using bacteriological approach and most interestingly qPCR enable to diagnose 48% of milk samples assessed "contaminated" using microbiological cultures.

Finally, to detail further whether qPCR assays could help with herd etiological diagnosis, a study was launched using composite milk samples including bulk tank milks. Indeed, 300 composite milk samples were collected from 60 different herds from Brittany. To get an overview of the herd status, additionally to bulk tank milk, 4 classes of lactating cows were selected for sampling: 1) first calf-heifers (<1 month calving), 2) multiparous cows (<1 month calving), 3) chronically infected cows and 4) dry cows.

Conclusions: This approach is the most adapted since it is difficult and expensive to analyze quarter or even individual cow milk requiring to sample a significant cow number (15 to 35% of the herd) in a limited time laps. qPCR analysis are currently ongoing.

These data confirmed qPCR assay as a good alternative to bacteriological approach: less cost-effective, enabling high throughput analyses and usable for composite milks diagnosis which is a blocking step for herd diagnosis.

CASE STUDY: Incidence of Mastitis before and after Vaccination at a Farm in Northern Spain

Juan M. Echeverria¹*Cristina Arrieta¹Pere Ordiz²Anna Targa²

¹SERGASI, Pamplona, ²Laboratorios HIPRA SA, Amer (GIRONA), Spain

Objectives: The objective of this paper is to document the results obtained from one field experience using a vaccine for mastitis (STARTVAC®, LABORATORIOS HIPRA, S.A. SPAIN) , to assess its efficacy at a dairy cattle farm with 140 cows in northern Spain.

Materials and Methods: 120 lactating cows and 20 dry cows in a farm with 2 milking robots were used for this trial.

The main mastitis related pathogens were: Staphylococcus aureus, Escherichia coli and Streptococcus uberis. 1 dose (2ml) of the vaccine was administered to all cows the same day. 21 days later all animals were revaccinated.

Milk production and bulk tank milk somatic cell count were evaluated every two days one year before and after vaccination. New infections rate, cure rate and % of chronic cows were analyzed, during lactation and at dry off, using the individual Somatic Cell Count (SCC) data from the Monthly Milk Record . As agreed by the scientific community, the threshold of 200,000cells/ml was established in order to differentiate healthy udders from infected ones.

Results: Milk yield per cow and day was 20L before vaccination and 29.22L after vaccination. Milk yield per lactating cow and day was 31L before vaccination and 32L after vaccination.

The average SCC before vaccination was 236,000 cells/ml and after vaccination it was 195,000 cells/ml.

New infections decreased in first lactation cows from 8,45% to 5.25%. In adult cows, new infections decreased from 15% to 8.25% and, at dry-off, they decreased from 20% to 8.5%.

The cure rate at lactation in heifers rose from 42.6% before vaccination to 60% after vaccination but in adult cows this trend was the opposite, from 36.6% to 30%. At dry-off the cure rate raised from 38% before vaccination to 91% after it.

Finally, the percentage of chronic cows went down from 6% to 3.5% in heifers, from 20% to 16.5% in adult cows and from 17% to 2.5% at dry-off.

Conclusions: Vaccination was successful in this farm. Milk production and cure rate at lactation, in heifers and at dry-off increased after vaccination. New infections decreased after vaccination and cure rate in heifers and at dry- off improved.

Udder Health & Milk Quality

P04-004-224

Effectiveness of tylosin five-day systemic injection in dry cow therapy

Yosuke Hamajima^{1*}

¹Akabane Animal Clinic, Tahara, Aichi, Japan

Objectives: Staphylococcus aureus (SA) and Esculin positive streptococcus (E-strep) including Streptococcus uberis are gram-positive difficult-to-treat mastitis organisms. They also cause subclinical mastitis without clear symptoms but with high somatic cell counts (SCC). Dry period is considered to be important for chronic mastitis treatment period, and systemic treatment with tylosin injection is popularly conducted as dry cow therapy (DCT), especially for controlling SA mastitis. The objective of this study was to examine the effectiveness against subclinical mastitis with tylosin (Tylan200) five-day systemic injection as DCT.

Materials and Methods: In 11 commercial dairy farms in Japan, 331 cows which were 7 days prior to drying-off (totally 1214 quarters with no clinical symptoms), were checked by California mastitis test. The quarter milk samples showing a strong positive reaction were cultured for microbiological examination and measured for SCC. The quarters with particular gram-positive organism (SA, E-strep, Coagulase-negative staphylococci (CNS)) were enrolled in the treatment trial. Cows having target quarters received 5-day Tylan200 injection intramuscularly (30ml per day) accompanied by cefapirine intramammary infusion. Teat sealants were not used. Quarter milk samples were collected at 1 and 2 weeks after calving, and served for microbiological examination and SCC. These cows were observed for 30 days after calving for clinical mastitis symptoms.

Results: The positive rates of each organism were as follows: SA 0.9% (11/1200); E-strep 1.8% (22/1200); CNS 1.4% (17/1200). The samples with contamination were eliminated from the analysis. Bacterial cure was defined as negative bacteria culture on both milk sampling after calving, and without any clinical mastitis until 30th day in milk. The quarters failing to complete sampling were also eliminated. The cure rates of each organism were as follows: SA 66.7% (6/9); E-strep 66.7% (8/12); CNS 100% (2/2). No significant differences were found for the cure rates between the 3 groups.

Conclusions: Gram-positive organism cure rates of Tylan200 injection DCT reported by other groups were 80% and 87%. Bacterial species identification was not clear in these reports, therefore this is first report to research the effectiveness of 5-day Tylan200 systemic injection for specific difficult-to-treat organisms. The cure rates of SA and E-strep subclinical mastitis were both 66.7% in this study. It is suggested that Tylan200 is effective to use in DCT for these difficult-to-treat gram-positive organism infections. Since the number of samples in this study was not enough, further studies are needed to validate this effect in other dairy herds.

P04-004-225

Udder health in a dairy herd using an off-licence administration protocol of vaccine containing *Escherichia coli* (J5) and *Staphylococcus aureus* (CP8).

Tom Greenham ^{1*}

¹Lambert Leonard & May, Whitchurch, United Kingdom

Objectives: This retrospective study aimed to describe udder health parameters in a single dairy herd before and after vaccination with *Escherichia coli* (J5) and *Staphylococcus aureus* (CP8) (Startvac; Laboratorios Hipra, Girona). The licensed programme involves administration of targeted periparturient doses. This protocol can be impractical to deliver on some units, leading to adoption of a simpler programme in which paired starting doses precede whole herd quarterly repeat vaccination. The objective of this study was to identify trends in mastitis cases and somatic cell count, looking for associations with use of the off-licence vaccination programme.

Materials and Methods: A dairy unit was recruited comprised of five hundred pedigree Holstein cows, permanently housed, with an even calving pattern throughout the year. A protocol had been implemented in which two vaccine doses (Startvac) were administered to the whole herd at a three week interval, followed by repeat doses at three month intervals. Clinical mastitis data was recorded contemporaneously by the farm staff. Individual cow level somatic cell counts were sampled every four weeks (Cattle Information Service, Telford). These three areas were examined for twelve months preceding the use of the vaccine and thirty months following the commencement of vaccination. Mastitis data was collated in to monthly case rate and, along with somatic cell count values, underwent descriptive analysis (Excel 2010, Microsoft Corporation). The dataset was then examined by univariate analysis of monthly medians (Mann-Whitney) and monthly means (two sample t-test after Johnson's transformation to account for non-parametric distribution) for the periods of the study preceding vaccination and following commencement of the programme (Minitab 17.1.0, Minitab inc.).

Results: Clinical case rate for the period preceding vaccination had a mean of 3.85 index quarter cases per hundred cows per month (95% CI 3.34, 4.35) and 4.38 total quarter cases per hundred cows per month (95% CI 3.80, 4.97). This case rate was not statistically different for the twelve month period immediately after commencement of vaccination, with index cases of 3.73 per hundred cows per month (95% CI 2.86, 4.61) and total case rate of 4.53 per hundred cows per month (95% CI 3.58, 5.47). The final eighteen months of the dataset had a mean case rate of 2.99 index quarter cases per hundred cows per month (95% CI 2.55, 3.44) and total case rate of 3.41 per hundred cows per month (95% CI 2.88, 3.94). The index case rate in the final period of the study was significantly lower than the period preceding vaccination by 0.86 cases

per hundred cows per month ($p=0.011$). Total cases were reduced by 0.97 cases between these two periods ($p=0.014$). Median case rates for these periods were similarly reduced, with a reduction of 0.85 index cases per hundred cows per month ($p=0.014$) and a reduction of 0.95 total cases per hundred cows per month ($p=0.016$). This equates to a reduction of approximately fifty-one index cases (fifty-seven total cases) for the herd per year.

Somatic cell count was relatively stable over the period of the study. No statistically significant differences in cell count were observed between the periods prior to vaccination and following commencement of the programme.

Conclusions: A reduction in mastitis rate started nine months after commencement of vaccination and continued over the remainder of the study. Multivariate analysis was beyond the scope of this dataset, so it was not possible to draw firm conclusions about causality. However, other than the vaccination programme, no major changes were made during the study period that would influence udder health. The temporal trend corresponds with previous reports of efficacy for the 'off-licence' vaccination protocol and supports earlier work suggesting that off-licence quarterly vaccination (Startvac) reduces the impact of intramammary infection in dairy cows.

Udder Health & Milk Quality

P04-004-226

Prevalence Of Milk Pathogens From Bulk Tank Milk In Azorean Pastures

Carla Azevedo ^{1*} Diana Pacheco ² Luisa Soares ² Roger Guix ¹ Jaime Maldonado ¹ João Simões ³

¹HIPRA, Amer, Spain, ²AJAM, São Miguel, ³UTAD, Vila Real, Portugal

Objectives: To our knowledge no prevalence's of a milk pathogens wide range, using multiplex qPCR technique from pastures of San Miguel Island (Azores, Portugal) were described before. The aim of the present study was to determine the apparent prevalence of a large wide of milk pathogens from BTM of Azorean dairy herds using a multiplex PCR method.

Materials and Methods: From all regions of San Miguel- Azores, 92 dairy herds considering a total of 5520 adult cows were used. These herds represented 5.0% (1833) of total dairy farms according data officially reported (2014) in San Miguel Island.

A BTM sample from each selected herds was collected using the (Startcheck®) sampling kit (HIPRA, Spain), according the manufacturer instructions, in order to determine the presence of coagulase-negative staphylococci (CNS), *Escherichia coli*, *Staphylococcus aureus*, *Corynebacterium bovis*, *Enterococcus* spp., *Streptococcus dysgalactiae*, *Streptococcus uberis*, *Actinomyces pyogenes*/*Peptostreptococcus indolicus*, *Klebsiella* spp., *Streptococcus agalactiae* and *Serratia marcescens*.

The extraction and amplification of the DNA were performed using a real time PCR (PathoProof™ Mastitis Complete-12 Kit; Thermo Fisher Scientific Inc., MA USA), with some modifications. A qPCR positive result was recorded when cycle threshold values were ≤ 37 and a sigmoidal amplification plot was obtained.

Results: In overall, all the 11 species/groups were detected by the qPCR assay. The mean number of bacteria species or groups for BTM was 5.6 (confidence interval 95% between 5.2 and 5.9). The group of

CNS were detected in all (100%) BTM samples. *E. coli* (75.0%), *S. aureus* (62.0%), *Corynebacterium bovis* (57.6%), *Enterococcus* spp. (55.4%), more than 50% of the herds. The remaining milk pathogens, *Streptococcus uberis*, *Actinomyces pyogenes/Peptostreptococcus indolicus*, *Klebsiella* spp., *Streptococcus agalactiae* and *Serratia marcescens* were present in 41.3%, 41.3%, 37.0%, 32.6% and 3.3% of the BTM samples, respectively.

Conclusions: We have presented baseline figures for 11 mastitis pathogens/groups in BTM samples from Azorean dairy herds. Both environmental or contagious bacteria, CNS, *E. coli* and *S. aureus* are the pathogens more commonly found. These results emphasize once again the importance of implementing mastitis control plans for the control of milk quality in the Azorean dairy herds.

P04-004-227

The effectiveness of different pre- and post-milking teat disinfectants against *Prototheca zopfii* algae

Peter Kovacs¹·Adam Kovacs¹Geza Szita²Viktor Jurkovich¹Endre Brydl¹Laszlo Konyves¹

¹Department of Animal Hygiene, Herd Health and Veterinary Ethology,

²Department of Food Hygiene, Szent Istvan University Faculty of Veterinary Science, Budapest, Hungary

Objectives: Since the first identification, the *Prototheca zopfii* became the 4th most common mastitis pathogen in Hungary. Without an effective treatment the only way to control this disease is prevention, and in this, the before and after milking teat disinfection plays a major role.

Materials and Methods: For our experiment we collected four different pre dipping and nine different post dipping products from Hungarian dairy herds. We wanted to provide the exact same conditions every time, to standardize the experiment, therefore we made artificial teats (fingers of plastic gloves filled with cotton swabs) and after proper disinfection these teats were used. Every teat was dipped into a *Prototheca zopfii* broth, and the disinfectants were used on wet and dry teats as well. After the necessary waiting time, the teats were pushed to Sabouraud agar plates. After 48 hours of incubation on 37°C the number of algae colonies was counted on the agar plates.

Results: We compared four different pre dipping products. The polyhexamethylene biguanide (PHMB) was totally ineffective, while the chlorhexidine was much more effective but didn't kill all the algae on the teat. In both cases the wet teats has much worse results than the dry teats. The didecyl-n methyl ammonium chloride and the PVP-iodine based products were able to kill all the algae on the wet and the dry teats too. From the nine post dipping products four contained lactic acid in different concentrations. One of them was effective while the other three has moderate effectiveness. The five iodine based post dipping products has better effectiveness, especially on dry teats, but slight differences could be seen according to the amount of the active material concentration of the products.

Conclusions: In case of teat disinfection the agent is only one of the things which have an effect on the result. In the literature usually the iodine based products are advised against the algae and we found that most of the time they really work. But these are not the only good active materials, and other factors can play a major role in the effectiveness of the disinfection. The proper dipping, and the leaving of unnecessary teat washing also can be important.

Pathogens Agents of the Udder isolated Milk Reception Boat of Goats with Mastitis The Municipality Oof Tanhuato Michoacán

Carlos Bedolla^{1*} and Lucio D.R. 1, Sánchez P.V.M. 1, Castañeda V.H. 2, Velázquez O.V. 3, García C.E. 1, Bedolla G.J.C. 1 ¹Faculty of Veterinary Medicine and Animal Science of the University Michoacana of San Nicholas of Hidalgo. ²University Center for Biological and Agricut

¹Microbiological Laboratory, University Michoacana of San Nicholas of Hidalgo, Morelia, Michoacán, Mexico

Objectives: Identify the pathogens agents of the udder isolated milk reception boat of goats with mastitis the municipality of Tanhuato, Michoacán

Identify the presence of *Staphylococcus aureus* as the main causative agent of mastitis in goats Tanhuato Township, Michoacán

Materials and Methods: The number of sample units (n = 49 stables) was calculated using a random model with proportional distribution function of the system characterization by small-scale dairy and major conglomerates. Sampling within herds was per cluster, ie a milk sample pot of receipt of each production unit was taken. the sampling of milk using for this test tubes sterilized sealing plug in which the necessary identification previously stable are scored. The test tube is placed inclined to keep out dirt. The sampling was made directly from the milk storage tanks. The sample tube was filled with two thirds at most. Finally, the sample tubes were placed on a rack placed in a sealed cooler for further transport to the laboratory of bacteriology of USAD of the Faculty of Veterinary Medicine and Animal Husbandry for immediate processing or refrigeration at 4 ° C. The processing of the milk samples obtained was held on sampling or the next day. Samples were seeded in 110 staphylococcal agar, azide blood agar and Mc Conkey agar. Then, the agar plates were incubated at 37 ° C and examined after 24 and 48 hours. The isolates were identified by colonial morphology, Gram stain, catalase test, coagulase test and the test of mannitol and gelatin. A isolates Mc Conkey agar, they were made corresponding biochemical tests for identification. The tests used were: Urea, citrate, SIM (Sulfide Indole Motility) test, Agar triple-sugar-iron for its acronym in English TSI, Middle MRPV (methyl red Voges-Proskauer).

Results: 49 samples of the boat receiving equal number of dairy herds goats, of which a total of 61 bacterial strains (100%) were isolated were collected. Of these, 29 (47.54%) were Gram-positive pathogens, while 32 (52.46%) Gram-negative pathogens. On the results of bacteriological analysis of the milk samples obtained in this study (Table 1), the staphylococci were identified as the main etiologic agents Gram-positive mastitis, among which the *S. aureus* as the main causal agent 21 insulation, equivalent to 34.43%, as well as coagulase negatives which mainly found pathogen was *Staphylococcus epidermidis* with 8 isolates representing 13.11%, results appear to be similar to an investigation by Ferrer, et al (1993) who obtained 12 cases, equivalent to 11.5% of *Staphylococcus aureus* and 46 equivalent to 44% divided into agents coagulase negative cases.

Conclusions: It is concluded that *Staphylococcus aureus* was the main pathogen found in samples of milk pot receiving goats Tanhuato municipality, Michoacan, followed by *Proteus mirabilis*, coagulase Negative (*Staphylococcus epidermidis*) and agents Gram negative pathogens: *Citrobacter intermedium*, *Proteus rettgeri*, *liquefaciens* *Serratia*, *Alcaligenes faecalis* and *Citrobacter freundii*.

Determination of the quality of Bovine Milk produced in the municipality of TARÍMBARO MICHOACÁN

Carlos Bedolla ^{1,*} and Bedolla C.C. ¹, Lucio D.R. ¹, Sánchez P.V.M. ¹, Mejía A. R. ¹, Castañeda V.H. ², Velázquez O.V. ³, García C.E. ¹, Bedolla G.J.C. ¹ ¹Faculty of Veterinary Medicine and Animal Science of the University Michoacana of San Nicholas of Hidalgo. ²University Centre

¹Microbiology Laboratory, University Michoacana of San Nicholas of Hidalgo, Morelia, Michoacán, Mexico

Objectives: The aim of this study was to determine the quality of bovine milk produced in the municipality of Tarimbaro Michoacan, through California test, Lactoscan and Microbiological Control.

Determine the percentage of butterfat, protein, and colony forming units/ml in milk samples obtained Tarimbaro municipality, Michoacan.

Materials and Methods: The study was conducted from september of 2012 to may of 2013 in the municipality of Tarimbaro, Michoacan. 100 dairy herds of the same number of production units of municipality Tarimbaro, Michoacan during the morning milking were sampled. To do this, a milk sample pot of receipt of each herd, previously mixed with a tablespoon placing the sample in a plastic pallet for California test was taken. Then the other part of the sample is poured into a glass jar previously sterilized. Subsequently, we proceeded to place samples in a sealed cooler at a temperature of 4 °C for transport immediately bacteriology laboratory of the Faculty of Veterinary Medicine UMSNH for processing. Samples were analyzed by casting technique plate, both for coliform and for mesophilic aerobic bacteria (BMA).

Results: It was found that 94% of the samples were negative, and 6% grade traces with test of California, that is of excellent quality according to international standards. Regarding the determination of butterfat in g/L with Lactoscan analyzer based on the NMX-F700-COFOCALEC 2004 standard, it was found that 69% of the samples corresponded to class A, 5% to class B, 6% to class C, while the remaining milk (20%) was found outside the norm. As for the results of bacteriological analysis for BMA, these are also interpreted according to the NMX COFOCALEC F-700, (2004), found that 46% of the samples corresponded to class 1, ≤100,000 CFU/ml, 11% to Class 2, 12% in Class 3, 7% to the Class 4, while the rest (24%) containing more than 1,200,000 CFU/ml, were classified outside the provisions of this standard.

Conclusions: It is concluded that the milk produced in the town of Tarimbaro, Michoacan is good quality, and to comply with the parameters established nationally and internationally. Making it suitable for consumption by the public consumer without risk.

Bacterial profiles and risk factors of intramammary infections in french dairy herds with high bulk tank milk somatic cell countOlivier Salat ^{1,*}¹veterinary clinic of Haute Auvergne, Saint Flour, France

Objectives: High milk somatic cell counts keep a major concern in dairy herds. In such herds, a rational process must be implemented to understand the infection dynamics. Identification of intramammary infection risk factors is just a step. Diagnosing the aetiology of intramammary infection makes up the other step, and it is critical to understand what happens in these dairy farms

Materials and Methods: This study presents bacterial profiles and risk factors reported in 66 dairy herds with concern about high bulk tank milk somatic cell count. All these farms were visited to evaluate management practices, housing conditions and milking routines. Dry cow routines and treatment protocols were also recorded. During the visit, a CMT (Californian Mastitis Test) was performed on the cows with high somatic cell counts (≥ 300 000 cells/ml) and the positive quarters were aseptically sampled for culture. When the same pathogen was frequently isolated, susceptibility to six antimicrobials was looked up. When the isolated strains showed the same antibioresistance pattern, we concluded that it was the same contagious strain of the pathogen.

Results: In about 40% of the herds, bacteriological exams revealed that one contagious strain was responsible of more than 70% of intramammary infections, and *Staphylococcus aureus* was isolated in more than ¾ of these herds. Strains of *Streptococcus uberis* (2 herds), *Streptococcus dysgalactiae* (2 herds), *Staphylococcus caagulase negative* (1 herd) and *Escherichia coli* (1 herd) were also identified as contagious bacteria. In the other herds, we found a variety of pathogens, with *Staphylococcus aureus* and *Streptococcus uberis* as the most prevalent and equally responsible of more than one half of intramammary infections.

The main risk factors of Intramammary infections were poor milking hygiene, no early detection of clinical mastitis and no prevention of contamination by milking unit. There was no specific risk factor in the herds where contagious bacteria were isolated

Conclusions: When an effectively contagious bacteria circulates within a herd, which is found in about 40% of dairy herds with high bulk tank milk somatic cell counts, the main factor explaining intramammary infections is the contagious potential of the pathogen.

Trends in U.S. Milk Quality Based on Bulk-Tank Somatic Cell CountsJason Lombard ^{1,*}Christine Kopral ¹Kathe Bjork ¹¹USDA:APHIS:VS, Center for Epidemiology and Animal Health, Fort Collins, CO, United States

Objectives: Bulk-tank somatic cell counts (BTSCCs) are used as one measure of milk quality. The maximum BTSCC allowed in milk varies in countries around the world. The current limit in the United States is 750,000 cells/mL, while other countries such as the EU have limits of 400,000 cell/mL. BTSCCs are important in international trade since exporting countries are required to meet the limits set by importing countries. In 2012, the EU implemented regulations that require milk products exported to the EU have a maximum BTSCC of 400,000 cells/mL. The objective of this study was to evaluate changes in bulk-tank somatic cell counts (BTSCC) from 2000 to 2014.

Materials and Methods: BTSCC data from four Federal Milk Marketing Orders (FMOs), representing about half of the milk marketed in the United States, were used to evaluate changes in BTSCCs. The four FMOs were Mideast, Upper Midwest, Central and Southwest. Data were

collected monthly and included herd identification, FMO, kilograms of milk shipped, and official BTSCCs. These data represent all milk shipped through the four FMOs, and conclusions apply only to this population of shipments. Because this study was a census, no estimates of sampling variability were calculated. A milk-weighted, 3-month geometric mean BTSCC was calculated and summed for all herds in each FMO and for all herds. SAS software was used for all calculations.

Results: In 2014, 45.0 billion kg of milk from 284,528 shipments representing 26,424 producers were monitored. Monitored milk represented 48.1% of the 93.6 billion kg of milk produced in the United States in 2014. The milk-weighted mean BTSCC decreased from 296,000 cells/mL in 2000 to 193,000 cells/mL in 2014, while the producer-weighted mean BTSCC decreased from 320,000 to 229,000 cells/mL during the same period. The Upper Midwest FMO accounted for approximately 45% of milk monitored on an annual basis. The Mideast FMO had the lowest BTSCCs for 13 of the 15 years evaluated. Seasonal variations in BTSCCs were consistent from 2000 to 2014, with the highest counts occurring in July through September. The summer increase in BTSCCs over baseline, however, has decreased from approximately 60,000 cells/mL to 35,000 cells/mL over the time period. The percentage of milk shipped from the 4 FMOs with BTSCCs of less than 400,000 cells/mL increased from 74.8 to 95.5%, while the percentage of shipments with counts less than 400,000 cells/mL increased from 65.0 to 86.8%.

Conclusions: BTSCCs in the United States have decreased approximately 35% since 2000. Many factors are likely responsible for these improvements in milk quality, e.g., producer motivation in the form of bonuses for providing quality milk, milk-quality regulations of countries that import U.S. dairy products, and an emphasis on improving milking procedures.

P04-004-232

The production effects and economic evaluation of vaccination against *Staphylococcus* and *E. coli* mastitis on a large-scale Hungarian dairy farm

Laszlo Ozsvari¹, Janos Muntyan², Istvan Filipisz³

¹Dept. of State Veterinary Medicine and Agricultural Economics, Faculty of Veterinary Science, Szent Istvan Univ., Budapest, ²Agro-M Zrt., Orosháza, ³Dunavet-B Zrt., Budapest, Hungary

Objectives: The mastitis has always been responsible for one of the most significant production losses in the dairy industry. The losses caused by mastitis were estimated to be more than € 50 million in 2011 (about € 200 per cow on average) in the Hungarian dairy cattle sector, and according to the recent surveys, the coagulase-negative *Staphylococci* (CNS) and the *Staphylococcus aureus* are responsible for most mastitis cases. The aim of our study was to present the production effects and the economic evaluation of mastitis vaccination against *S. aureus*, CNS spp. and *Escherichia coli* in a large-scale Holstein-Friesian dairy herd.

Materials and Methods: The study was carried out in a 700-cow Hungarian dairy herd, in which a large number of mastitis cases, mainly caused by *S. aureus* and CNS spp., resulted in high milk somatic cell counts (SCC), high culling rate in cows and significant treatment costs. The mastitis vaccination (Startvac®, Hipra) was started in 2010 on the farm. We surveyed the major milk production indices (average lactation and daily milk production, monthly SCC) and udder health parameters (occurrence and distribution of mastitis pathogens, number of clinical mastitis cases and udder treatments, mortality and culling rate in cows

due to mastitis) and their economic impact on the farm between 2006 and 2014. Thus, we were able to compare the losses caused by clinical mastitis (cost of curative treatments, discarded milk and cow replacement [mortality and culling]) in the 4-year-long period before the vaccination (2006-2009) with those in the 4-year-long period after the entire cow population was vaccinated (2011-2014) in order to conduct the cost-benefit analysis of the mastitis vaccination. In the economic analysis the reduction of losses due to clinical mastitis was considered as benefit and the expenditures of vaccination were taken into account as cost. All the benefits and costs occurred over the 9 years of the survey period were adjusted for the general price level in 2014.

Results: After vaccination the incidence and proportion of the CNS spp. in the mastitis cases has moderately dropped, nevertheless, the clinical mastitis cases caused by *E. coli* have disappeared and the occurrence of *S. aureus* remained low throughout the whole vaccination period. The average daily number of cows with clinical mastitis has significantly decreased after 2010 from over 30 to between 5 and 10 cows a day. So did the monthly number of mastitis treatments: from more than 800 in 2006 to less than 300 in 2014. Thus, the quantity of discarded milk has also greatly decreased (from 6.1% to 1.2% of the total milk production), and so did the curative mastitis treatment cost (from € 18.3 to € 10 per cow). The monthly average SCC has slightly diminished after 2010, but no significant decrease could be observed. The mastitis vaccination had no impact on cow replacement owing to mastitis.

At 2014 price level the cost-benefit analysis of mastitis vaccination shows that the yearly loss caused by clinical mastitis in the 4-year-long period before the vaccination (2006-2009) was € 206.3 per cow which decreased to an annual amount of € 138.0 between 2011 and 2014 when all the cows were vaccinated. It included the significant decrease in the cost of discarded milk and mastitis treatments, however, that of premature disposal increased because of the enlarged heifer raising costs. The mastitis vaccination yielded € 50.7 average annual profit (decrease in loss – cost of vaccination) per cow between 2011 and 2014. The vaccination as an investment had 3.37 benefit-cost ratio and 236.8% ROI.

Conclusions: The findings of the case study show that the mastitis vaccination significantly reduced the occurrence of clinical mastitis cases caused by *S. aureus*, CNS spp. and *E. coli* in the herd. According to the result of the economic analysis the mastitis vaccination (Startvac®, Hipra) was profitable on the surveyed farm, as the decrease in the loss due to mastitis coming from the improved udder health parameters exceeded the mastitis vaccination costs.

Udder Health & Milk Quality

P04-004-233

Disagreement between milk pathogens prevalence in segregated milking cows and bulk tank milk in Azorean pastures

Carla Azevedo^{1,1}, Diana Pacheco², Luísa Soares³, Roger Guix¹, Jaime Maldonado¹, João Simões⁴

¹HIPRA, Amer, Spain, ²University of Evora, Evora, ³Ajam, São Miguel, ⁴UTAD, Vila Real, Portugal

Objectives: The aim of the present study was to determine the apparent prevalence of a large wide of milk pathogens from BTM using a multiplex PCR method and compare it with the pooled samples from mastitic cows segregated at milking time from Azorean dairy herds.

Materials and Methods: From all regions of San Miguel- Azores, 92 dairy herds considering a total of 5520 adult cows were used.

The separation of mastitic cows, due to the presence of clinical mastitis (untreated or in treatment) or subclinical mastitis with high SCC detected by California Mastitis Test, at milking time was considered for herd inclusion on the present study. A milk pooled sample from all quarters of these cows (mean = 3) were collected in each farm. In simultaneous, after milking all cows, a sample was collected from BMT.

All final samples were collected using the Startcheck® sampling kit (HIPRA, Spain), according the manufacturer instructions, in order to test the presence of coagulase-negative staphylococci (CNS), *Escherichia coli*, *S. aureus*, *Corynebacterium bovis*, *Enterococcus* spp., *Streptococcus dysgalactiae*, *Streptococcus uberis*, *Actinomyces pyogenes* / *Peptostreptococcus indolicus*, *Klebsiella* spp., *Streptococcus agalactiae* and *Serratia marcescens*.

The extraction and amplification of the DNA were performed using a real time PCR (PathoProof™ Mastitis Complete-12 Kit; Thermo Fisher Scientific Inc., MA USA), with some modifications. A qPCR positive result was recorded when cycle threshold values were ≤ 37 and a sigmoidal amplification plot was obtained.

Results: In average, each farm presented 4.6 (CI95% from 4.3 to 4.9) and 5.6 (CI95% from 5.2 to 5.9) bacteria species/group from SMC and BMT respectively. Coagulase-negative staphylococci, *Escherichia coli*, *Staphylococcus aureus*, *Enterococcus* spp., *Corynebacterium bovis* and *Streptococcus* spp. presented the higher apparent prevalence on both samples type (upper 95% IC > 50%). A high correlation of apparent prevalence from each pathogen between SMC and BMT samples were observed ($Rho = 0.90$; $n = 11$; $P < 0.01$) inter-herds. However, the agreements between these apparent prevalences, intra-herd, were always low (Kappa coefficient < 0.70).

Conclusions: In conclusion, high prevalences of bacteria species/groups were detected in BTM from Azorean pastures. Although the segregation of cows may be a potentially favorable practice, their number on each farm seem to be too small to be representative and consequently not an indicator of agents in BTM on the same herd. In consequence, a holistic approach on mastitis diagnosis, treatment and control should be considered in Azorean dairy farms.

Selective dry cow therapy in the UK using OrbeSeal™

Judith Roberts^{1,*}

¹Zoetis, Walton Oaks, United Kingdom

Objectives: Selective dry cow therapy is increasingly becoming important in UK dairy herds. The decision about whether a cow should receive antibiotic dry cow therapy (ADCT) in addition to an internal teat sealant or an internal teat sealant alone should be based on farm information including somatic cell count recordings, clinical mastitis case rate and knowledge of the predominant mastitis pathogens on the farm.

Materials and Methods: At Zoetis we believe it is important that selective dry cow therapy using OrbeSeal is performed correctly using all the farm information available. The flowchart below is designed to offer a guide to decision making for determining the appropriate dry cow therapy at the herd, group and then individual animal level.

Stage 1 - Herd level

Do you record clinical mastitis cases in an accessible format to analyse?

Have you performed bacteriology to understand the pathogens causing clinical and subclinical mastitis on your farm?

Do you carry out monthly individual cell count recordings?

Yes to all of the above - you can now determine which groups of cows will be eligible for selective dry cow therapy

No to any of the above - based on herd level factors you do not have enough information to determine cow groups for performing selective DCT, Discussions are required between vet/farmer and milk purchaser about recording farm data and carrying out milk sampling.

Results:

Stage 2 - Group level

Split herds into low, medium and high SCC to identify groups within the herds for dry cow therapy.

Stage 3 - Individual cow decision making

Once cows determined appropriate for selective dry cow therapy have been identified, a final check should be carried out to make sure the cow is not of high risk for mastitis during the subsequent lactation.

Individual cow risk factors for mastitis

- Environment: high bacterial populations at the teat end
- Production: high milk production across lactation, poor or delayed formation of keratin plug
- Drying off: increasing parity, high milk production at drying off, gradual method of dry off, poor hygiene and cleanliness at dry off, milk leakage at dry off, poor teat end integrity (eg damage, hyperkeratosis)

Conclusions: Selective dry cow therapy is important in UK dairy herds to reduce the usage of antibiotics and on some farms as part of a mastitis control programme. OrbeSeal prevents mastitis acquired during the dry period and is therefore a vital tool in mastitis control, whether used with or without an antibiotic dry cow product. The use of OrbeSeal alone should be targeted at cows which have a reduced risk of having a mastitis infection at dry off. OrbeSeal should always be infused in a clean and hygienic manner to reduce the risk of iatrogenic infection.

Comments: To discuss the use of OrbeSeal either alone or with an antibiotic dry cow product further, please contact a member of the Zoetis Ruminant Technical team or email: customersupportUK@zoetis.com.

Serum Biochemical Profile Of Healthy Murrah Buffalo Calves In The Neonatal Period

Damazio C. Souza¹*Daniela G. Silva¹Thais G. Rocha¹Bruno M. Monteiro²Leticia C. Fiori¹Lana C. C. Fonseca¹Rinaldo B. Viana³José J. Fagliari¹

¹Departamento de Clínica e Cirurgia Veterinária, Faculdade de Ciências Agrárias e Veterinárias - FCAV - Unesp - Jaboticabal, Jaboticabal, ²Faculdade de Medicina Veterinária e Zootecnia, Universidade de São Paulo, São Paulo, ³Instituto da Saúde e Produção Animal, Universidade Federal Rural da Amazônia, Belem, Brazil

Objectives: The present study aims to establish a serum biochemical profile of healthy Murrah buffalo calves, from birth to 30 days of age, and also to evaluate indirectly the passive immunity transfer on those animals

Materials and Methods: The research project was evaluated by the Ethics Committee on Animal Use (CEUA) of FCAV / UNESP / Jaboticabal Campus and approved under protocol number 010028/2014. Thirty five healthy Murrah buffalo calves born from healthy dams in eutocic births were evaluated. The research was made in São Paulo State - Brazil. Blood samples for blood serum separation were collected after birth (M0), and with 24h (M1), 48h (M2) and 72h (M3) of age, and after 7 (M4), 14 (M5), 21 (M6) and 30 (M7) days of life to determine the serum activities of gamma glutamyl transferase (GGT), alkaline phosphatase (ALP), aspartate aminotransferase (AST) and creatine kinase (CK) and serum concentrations of total protein (TP), albumin (Alb), iron (Fe), total calcium (Ca) and phosphorus (P) by spectrophotometry using commercial reagents. The blood samples were centrifuged at 1,000 x g for 10 minutes, and serum samples were frozen at -20°C until analysis.

Results: The results are as follows: GGT (U/L) - M0: 19.1±6.10; M1: 1.421±803; M2: 544±354; M3: 313±177; M4: 153±99.5; M5: 63.0±43.8; M6: 34.6±27.5; M7: 18.1±7.67. ALP (U/L) - M0: 142.5±57.5; M1: 1,272±638; M2: 501±271; M3: 301±140; M4: 207±107; M5: 141±52.5; M6: 115±37.3; M7: 103±42.5. AST (U/L) - M0: 43.7±15.8; M1: 106±17.4; M2: 99.2±16.7; M3: 893±13.9; M4: 77.4±8.90; M5: 74.1±31.3; M6: 69.8±21.1; M7: 70.9±13.0. CK (U/L) - M0: 121±53.1; M1: 274±114; M2: 164±82.6; M3: 136±85.5; M4: 138±47.5; M5: 234±120; M6: 250±122; M7: 255±98.7. TP (g/dL) - M0: 4.80±0.26; M1: 8.10±1.31; M2: 8.22±1.34; M3: 8.14±1.39; M4: 7.88±1.20; M5: 7.56±0.96; M6: 7.21±0.79; M7: 6.77±0.79. Alb (g/dL) - M0: 2.44±0.24; M1: 2.11±0.23; M2: 2.19±0.23; M3: 2.31±0.24; M4: 2.48±0.20; M5: 2.56±0.20; M6: 2.65±0.24; M7: 2.57±0.29. Fe (µg/dL) - M0: 84.7±29.7; M1: 80.7±42.9; M2: 119±58.9; M3: 116±72.3; M4: 148±135; M5: 138±82.1; M6: 191±102; M7: 187±79.8. Ca (mg/dL) - M0: 9.86±1.08; M1: 9.60±1.32; M2: 10.5±1.04; M3: 10.6±1.18; M4: 10.74±1.12; M5: 10.1±1.14; M6: 9.92±1.32; M7: 9.47±1.35. P (mg/dL) - M0: 5.39±0.73; M1: 6.58±1.47; M2: 7.58±1.88; M3: 9.04±1.74; M4: 9.38±1.12; M5: 8.63±0.88; M6: 8.46±0.90; M7: 8.28±1.09.

Conclusions: These results help to establish a biochemical serum profile of healthy Murrah buffalo calves in the neonatal period, aiding in the interpretation of physiological and pathological conditions that may have an impact on the evaluated parameters. GGT activity as well as TP levels in M1 showed results well above of the satisfactory levels for a secure passive immunity transfer from the dams to the calves

Comments: Thanks For FAPESP for the aid Process n.2014/09246-5

Leukogram And Acute Phase Proteins Concentrations Of Calves With Rotavirus Diarrhea

Thais Rocha¹*Andressa Francisca S. Nogueira¹Kalina Maria G. M. Simplicio¹Daniela G. Silva¹Paulo Cesar Silva¹Maria da Gloria Buzinaro²Jose Jurandir Fagliari¹

¹Veterinary Clinic and Surgery , ²Preventive Veterinary Medicine, FCAV-Unesp, Jaboticabal, Brazil

Objectives: The aim of the present study was to characterize changes in leukogram and acute phase proteins profile as a result of the occurrence of rotavirus diarrhea in calves throughout the first month of life.

Materials and Methods: Blood and fecal samples were collected from twenty-four Holstein calves allotted in three experimental groups with eight animals each: calves that did not present diarrhea neither rotavirus infection (group A), calves that presented diarrhea, but tested negative for rotavirus in feces (group B), and calves that presented diarrhea and tested positive for rotavirus in feces (group C) before colostrum intake (moment 0) and at 1, 2, 7, 15, 21 and 30 days of age (Experiment 1). Also, whenever the animals presented episodes of diarrhea, blood and fecal samples were collected at 24-hour intervals until the end of clinical signs (Experiment 2). Leukogram was performed in an automatic counter and acute phase proteins in serum were electrophoretically separated in polyacrylamide gels containing sodium dodecyl sulphate (SDS-PAGE); rotavirus in feces was detected by polyacrylamide gel electrophoresis (PAGE). Data from experiment 1 were analyzed by ANOVA and the differences between groups were compared by Tukey's test, considered significant at P<0.05. Data from experiment 2 were subjected to the HSD test.

Results: Total leukocyte, neutrophils, and lymphocyte counts did not differ among groups A, B, and C throughout the first 30 days of life, although, in experiment 2, least square means for total leukocytes and lymphocyte counts were significantly higher in the first day of diarrhea manifestation in group C when compared to group B. In experiment 1 ceruloplasmin and transferrin levels were significantly higher in group C than in groups A and B. Serum concentrations of haptoglobin and α_1 -acid glycoprotein did not differ significantly among groups throughout the experimental period. In the moments of diarrhea manifestation, least square means of ceruloplasmin and transferrin concentrations were higher in group C than in group B, whilst haptoglobin and α_1 -acid glycoprotein concentrations did not differ significantly between groups B and C.

Conclusions: These findings suggest that rotavirus diarrhea caused a more significant tissue damage followed by leukocyte response when compared to other causes of diarrhea affecting calves throughout the first month of life, and that ceruloplasmin may be a marker of rotavirus infection in calves.

Comments: Authors thank Fundação de Amparo à Pesquisa do Estado de Sao Paulo (FAPESP) for the financial support and scholarships granted (Processes 2011/02414-1 and 2010/10677-0).

Assessment of dietary isoquinoline alkaloids in the prevention of cryptosporidiosis in newborn calves

Filipe L. M. Mendonça¹, Rafael J. Silva¹, João P. Andrade¹, Layanne D. Ferreira¹, Horst I. Rogge², Luana C. A. Ferreira¹, Markus V. V. Araújo¹, Julia G. D. Carvalho¹, Antonio U. Carvalho¹, Elias J. Facury Filho¹

¹Departamento de Clínica e Cirurgia Veterinária, UFMG, Belo Horizonte, Brazil, ²Phytobiotics Futterzusatzstoffe GmbH, Eltville, Germany

Objectives: Diarrhea presents a high prevalence in newborn calves and is considered the main cause of mortality in this category. The infection by *Cryptosporidium* spp. is one of the main etiologies of this disease. Specific isoquinoline alkaloids have local anti-inflammatory effects and can contribute for the intestinal integrity. The objective of the study was to evaluate the effectiveness of Sangrovit® CS in the prevention of diarrhea caused by cryptosporidiosis in experimentally inoculated calves, by comparing the intensity and duration of the induced diarrhea.

Materials and Methods: A total of 26 newborn male calves (20 Holstein and 6 crossbred ¾ Holstein X ¼ Gir), were randomly divided into two groups of 13 animals each. Group A received isoquinoline alkaloids (10 g/animal/day of Sangrovit® CS divided in 2 meals/day) from the second meal of the 1st day of life until the 21st day of life. Group B (control group) received milk without any additives. All calves were orally inoculated on the third day of life with 1×10^6 *Cryptosporidium parvum* oocysts. The inoculum was obtained from a field case, amplified in a healthy calf and subsequently purified and kept in the laboratory of the UFMG's Clinic of Ruminants sector. All animals were evaluated daily from the 3rd until the 30th day of life for the occurrence, duration and intensity of diarrhea. In order to determine the fecal consistency, the following score was established: 0 (normal feces), 1 (pasty feces), 2 (watery feces), 3 (profuse diarrhea with watery feces) and 4 (bloody diarrhea). The scores 2, 3 and 4 were characterized diarrheal feces. Hemogasometry was performed each two day during diarrhea. Animals that have base deficit greater than 9 meq/l were hydrated to aid in recovery of the disease, and were considered with prognosis reserved.

Results: In group A, 84.62% of the calves had diarrhea lasting an average of 6.31 ± 6.49 days, while in group B all calves had diarrhea that lasted on average 11.55 ± 5.29 days. In group A, the number of animals that required hydration was 15.38% (2/13), lower ($P < 0.05$) than in group B with 69.23% (9/13). Furthermore, in group A no mortality was observed while in group B 15.38% (2/13) of the animals died in consequence of cryptosporidiosis. The consistency of fecal scores of treated calves were lower during the studied period and feces showed up more solids ($P < 0.05$) during the 6th, 7th and 8th day of diarrhea.

Conclusions: Oral administration of Sangrovit® CS decreased the intensity and duration of diarrhea symptoms and reduced the need to support treatments for clinical recovery as well as the mortality rate of the affected animals.

Clinical and Hematological findings in Neonate Holstein Heifers fed with whole and cell-free colostrum

Sylvia M. F. Novo¹, Juliana F. Reis¹, Camila C. Baccili¹, Bruno T. Silva¹, Natalia M. Sobreira¹, Milena A. Maia¹, David J. Hurley², Viviani Gomes^{1,*}

¹Internal Medicine, University of São Paulo, São Paulo, Brazil,

²University of Georgia, Athens, United States

Objectives: The neonatal period is critical for the survival of newborn heifers due to the adaptation to the environmental and immunological immaturity, making them dependent on maternal immune factors transferred by colostrum intake. The hypothesis of this study is that colostrum cells and their products, working with antibodies, can collaborate in the development of the innate and adaptive immune system to reduce the incidence and severity of disease during this period. So, the objective of this research was to evaluate the influence of colostrum cells on the health and dynamics of the hematological profile in heifers during the first 28 days of life.

Materials and Methods: In this study, healthy Holstein heifers (n=19) were selected using a clinical examination between birth and two hours of life. Heifers were distributed in two experimental groups: COL+ (n=9) which received fresh colostrum from their own dams; and group COL- (n=10) which received frozen colostrum containing no viable cells. Both groups received colostrum of the same quality measured by immunoglobulins concentration (70-120g/L – colostrometer and 23-32% - BRIX). Heifers were assessed before colostrum intake – D0; 24-48 hours after birth – D2; 7 days after birth (ab) – D7; 14 days ab – D14; 21 days ab – D21 and 28 days ab – D28. Heifers were given fecal and bronchopneumonia scores, umbilical palpation and hematological profile. Fecal scores were assigned as; 0- normal consistence, 1- pasty, semi-formed; 2- pasty with largest amount of water; or 3- liquid with fecal content adhered in the perineum and tail. Bronchopneumonia was scored using the following parameters: rectal temperature, cough, nasal and ocular secretion and ear position with a score of 0-3 for each based on severity. Calves were assessed as having bronchopneumonia when the sum of these scores was >5. Parametric data were evaluated between groups using an unpaired T test and analysis in time by ANOVA for repeated measures ($P < 0,05$). Qualitative data were presented in absolute values and frequencies and the groups were compared by Chi-square test.

Results: The frequency of diarrhea was high from D7 (COL = 55.6% and COL- = 70%) to D28 (COL+ = 44.4% and COL- = 50.0%) in both groups ($P = 0.418$), however, the COL- had a higher intensity score (typically 3) on D7. Bronchopneumonia was detected just one case in D21 in COL- calf. Umbilical inflammation was detected in 3 heifers at D14 and D28 in COL- calves. COL- heifers had lower numbers of red blood cells (RBC) ($6.5 \pm 0.8 \times 10^6/\mu\text{L}$) and less hemoglobin (HB) ($8.3 \pm 1.4 \text{ g/dL}$) than those from COL+ group ($\text{HE} = 7.2 \pm 0.8 \times 10^6/\mu\text{L}$; $\text{HGB} = 9.6 \pm 1.3$) at D14. The values for RBC, HB and hematocrit (HTC) decreased during this study. Anemia was detected during neonatal period, with higher frequency in COL- (40.0 and 50.0%) than the COL+ group (0.0%) at D21 ($P = 0,03$) and D28 ($P = 0,02$). The hematological profile revealed a peak of white blood cells (WBC) at D7 in both groups. COL+ calves had a gradual decrease in the number of WBC until D21, then an increase at D28. However, COL- group had decreased numbers of WBC through D28. Both groups had gradual decrease in neutrophils, and an increase in lymphocytes (Ly) over the course of the study. However higher numbers of Ly were observed on D7 in COL- calves relative to those receiving maternal cells ($3.8 \times 10^3/\mu\text{L}$ COL+ and $5.4 \times 10^3/\mu\text{L}$, $P = 0.02$).

Conclusions: Thus, we observed that the occurrence of diseases was similar between groups, except for umbilical inflammation. However, diarrheal scores 2 or 3 were observed more frequently in COL-calves. The hematological values of heifers that received cell free colostrum resulted in anemia and leukocytes alteration compatible with inflammatory process.

Effects of milk replacer crude protein content on Holstein-Friesian and Holstein-Friesian x Jersey cross dairy heifer calf growth pre and post-weaning

Emer Kennedy^{1,*} John Paul Murphy¹

¹Teagasc, Moorepark, Fermoy, Co. Cork, Ireland

Objectives: The objective of this experiment was to compare two commercially available milk replacers with differing crude protein (CP) contents (20% compared to 26%) offered to replacement dairy heifers during the pre-weaning period on weight and average daily weight gain (ADWG).

Materials and Methods: Sixty-two replacement dairy heifer calves were enrolled on an experiment at Teagasc Moorepark Research Farm, Co. Cork from 25 January to 23 October, 2015. Calves were blocked on the basis of date of birth (DOB; 5 Feb ± 7.2 days), birth BW (33 ± 4.7 kg) and breed (42 Holstein-Friesian (HF) and 20 Jersey x HF; JEX). They were randomly assigned to one of two feeding treatments: i) fed a 20% CP milk replacer (MR20) or ii) fed a 26% CP milk replacer (MR26). Treatments were replicated. All calves were removed from their dam within one hour of birth and fed 8.5% of birth BW in colostrum in one feed. Transition milk was offered for the subsequent three days. Milk replacer was group fed, at a daily rate of 6 litres/calf, was offered twice daily for the first four weeks and once daily thereafter. All calves were offered fresh water, ad libitum concentrate and hay throughout the milk feeding period. Calves were turned out to pasture from 5 weeks of age. Calves were weaned based on a pre-defined weight; ≥ 90 kg for HF and ≥ 85 kg for JEX animals; this allowed for breed differences in mature BW. Weaning was gradual over a one-week period. Following weaning, all calves were offered ad-libitum grass outdoors. Calves were weighed weekly pre-weaning and every two weeks post-weaning. As all calves were weighed on a fixed calendar date variation existed in the actual age of calves at each weighing event. Therefore, BW ±5 days at 140 and 240 days of age is reported. Data were analysed using mixed models in SAS. The model included treatment, replicate, breed, age and birth weight.

Results: There was no interaction between treatment and breed for any of the variables investigated, thus results will not be reported. It took the MR20 calves 6 days longer to reach their target weaning weight compared to MR26 calves (93 days). As designed and imposed, actual weaning weight was the same for both treatments (94 kg). At 140 days of age the MR20 calves weighed 122 kg while the MR26 calves weighed 129 kg (P<0.05). By 240 days there was still a difference (P<0.05) between both the MR20 (205 kg) and MR26 (214 kg) treatments. Average daily weight gain from birth to weaning was 0.66 and 0.60 kg/calf/day for the MR26 and MR20 calves, respectively (P<0.01). The ADWG from weaning to 240 days old was not different between the two treatments (0.80 kg/calf/day).

Conclusions: The results from this experiment show that differences in bodyweight post-weaning are due to differences which arose during the pre-weaning period. Feeding a 26% CP milk replacer compared to a 20% CP milk replacer ensures higher ADWG during the pre-weaning period, which will increase the likelihood of heifers attaining target bodyweight at key times during their first two years of life e.g. mating start date. Furthermore, there was no interaction between breed and milk replacer suggesting that all heifers should be offered a 26% CP milk replacer compared to a 20% milk replacer.

Immunity Development In Neonate Holstein Heifers Feeding Whole And Cell-Free Colostrum

Sylvia M. F. Novo¹ Juliana F. Reis¹ Camila C. Baccili¹ Bruno T. Silva¹ Natalia M. Sobreira¹ Pamela O. Lorenci¹ David J. Hurley² Viviani Gomes^{1,*}

¹Internal Medicine, University of São Paulo, São Paulo, Brazil,

²University of Georgia, Athens, United States

Objectives: The aim of this research was to evaluate the influence of colostrum cells on the development of immunity in heifers over the first 28 days of life. In this study, healthy Holstein heifers (n=19) were selected using a clinical examination between birth and two hours of life.

Materials and Methods: Heifers were distributed in two experimental groups: COL+ (n=9) which received fresh colostrum from their own dams; and group COL- (n=10) which received frozen colostrum containing no viable cells. Both groups received colostrum of the same quality measured by immunoglobulins concentration (70-120g/L – colostrometer and 23-32% - BRIX). Heifers were assessed before colostrum intake – D0; 24-48 hours after birth – D2; 7 days after birth (ab) – D7; 14 days ab – D14; 21 days ab – D21 and 28 days ab – D28. Immunological evaluations were performed using hematological assessment, immune phenotyping of, and in vitro cytokine production by peripheral blood mononuclear cells (PBMC) stimulated with BoHV-1 and bacteria. Parametric data were analyzed by unpaired T test and ANOVA for repeated measures (P<0.05), while nonparametric data was evaluated by Mann-Whitney U test and Wilcoxon test with Bonferroni correction.

Results: Peak numbers of white blood cells were observed in both groups at D7. COL- calves had a higher number of lymphocytes (Ly) (3.4 and 5.4x10³/μL) than COL+ calves (2.7 and 3.8x 10³/μL) at D0 and D7. Differences between groups in CD3⁺gamma-delta T cells were detected (10³/μL) at D0 (COL+=988.3 and COL-=1279.9; P=0.01) and D7 (COL+=1676.2 and COL-=2263.4; P=0.01). COL- calves also had more CD3⁺gamma-delta⁺ (10³/μL) at D7 (COL+=1580.6 and COL-=2352.2; P=0.00). The number of CD45⁺CD45RO⁻ (10³/μL) leukocytes was higher in COL- calves at D0 (COL+=2602.7 and COL-=3204.2; P=0.01) and D21 (COL+=951.7 and COL-=1265.6; P=0.03). Absolute values of CD45⁺CD45RO⁺ leukocytes were also different between COL+ and COL- calves at D7 (COL+=695.4 and COL-=1419.8; P=0.02). The production of cytokines by PBMC (1x10⁶ cells) was evaluated between D7 and D28 (due to low recovery of Ly at D0 and D2). PBMC, unstimulated or stimulated with BoHV-1 (Dose: 50μL, titre 10^{5.7} TCID₅₀), did not produce measurable cytokine under these conditions. PBMC from COL+calves produced more IL-17 (COL+=740pg/mL; COL-: zero) at D14 when stimulated with 5 μg of

ConA. In all calves, the PBMC response to *Escherichia coli* was higher than to inactivated *Staphylococcus aureus*[d1]. In general, PBMC from COL+ stimulated by bacteria produced IL-17 while COL- released IFN-gamma. Differences were detected between groups for interferon-gamma (COL+: zero; COL-: 225,33 pg/mL) at D21 when PBMC were stimulated with *Staphylococcus aureus*.

Conclusions: In conclusion, heifers that received whole and cell-free colostrum had a similar profile of blood Ly subsets. An increase in the number of memory cells (CD45⁺CD45RO⁺) was observed throughout the first month of life. Higher numbers of CD3⁺WC1⁻, CD3⁺WC1⁺ and CD45⁺CD45RO⁺ Ly in the COL- at D7 appeared to be associated with diarrheal disease in these calves based on clinical findings. PBMC from both groups showed greater ability to respond to bacterial stimulus than BoHV-1 under these culture conditions. However, cytokine profile presented by the two groups were different, with a higher level of Th17 produced in vitro by PBMC from COL+ calves.

Comments: This research was supported by grants from the Sao Paulo Research Foundation (project n. 2013/06152-7).

P04-004-136

Oral rehydration solutions containing glutamine for treating pre-weaning diarrhoea in calves : A critically appraised topic (CAT)

Gwen Rees ¹David C. Barrett ¹ and final year students at the University of Bristol School of Veterinary Sciences

¹Farm Animal Department, University of Bristol, North Somerset, United Kingdom

Objectives: Pre-weaning diarrhoea in calves is a significant issue worldwide, with high morbidity and mortality. Oral rehydration solutions (ORS) are the mainstay of treatment in mild to moderate cases. In human medicine, the addition of glutamine, an amino acid key to providing intestinal epithelial energy, has shown varying results. Some proprietary veterinary ORS contain glutamine, and this evidence synthesis aims to evaluate the available veterinary literature to provide an evidence-based answer to the clinical question: Does inclusion of glutamine in oral rehydration solutions improve recovery from mild to moderate diarrhoea in pre-weaned calves?

Materials and Methods: Evidence-based veterinary medicine (EBVM) has been defined as using the most reliable and relevant available scientific evidence in conjunction with clinical expertise to make the most appropriate decision about a veterinary patient, while considering the circumstances of each patient and its owner (Reyher et al. 2015). The use of evidence syntheses enables the practitioner to make evidence-based clinical decisions quickly in practice, and one example of such evidence synthesis is through a critically appraised topic (CAT). To create a CAT, a clinically relevant question arising in practice is identified, and the current literature is searched and appraised in order to form an evidence-based 'clinical bottom line' with which to help base decisions (Arlt et al. 2012, Fetters et al. 2014, Steele et al. 2013). This presentation summarises a CAT produced by staff and students at the University of Bristol's School of Veterinary Sciences.

The PICO question [Population][Intervention][Comparator][Outcome] In [pre-weaned calves with mild to moderate diarrhoea] does treatment with [ORS containing glutamine] compared with [ORS not containing glutamine] lead to [improved clinical recovery]?

Brooks, H.W., Gleadhill, A., Wagstaff, A.J. & Michell, A.R. (1997) Fallibility of plasma urea and creatinine as indices of renal function in diarrhoeic calves treated with conventional or nutritional oral rehydration solutions. *Veterinary Journal* 154: 35-39

Nappert, G., Zello, G.A. & Naylor, J.M. (1997) Intestinal metabolism of glutamine and potential use of glutamine as a therapeutic agent in diarrheic calves. *Journal of the American Veterinary Medical Association* 211: 547-553

Conclusions: The studies varied in quality and strength of evidence, and the majority were published almost 20 years ago. Many different outcomes were measured between the studies, including villus structure, plasma volume, packed-cell volume, renal parameters, demeanour and faecal consistency. All the studies found inclusion of glutamine in a high calorie ORS was beneficial, however, where inclusion of glutamine in a non-nutritious ORS was studied, the beneficial effect was lost.

Clinical bottom line: The inclusion of glutamine in a high calorie ORS results in improved clinical recovery from diarrhoea in pre-weaned calves.

Diagnostic accuracy of refractometry for assessing bovine colostrum quality: a systematic review and meta-analysis

Sébastien Buczinski ¹Jean-Michel Vandeweerd ²

¹University of Montréal, St-Hyacinthe, Canada, ²Université de Namur, Namur, Belgium

Objectives: Provision of high quality colostrum (i.e. with immunoglobulin G (IgG) concentration $\geq 50\text{g/L}$) is the first step to ensure good passive transfer immunity for young calves. Assessment of the refractive index using a Brix scale (in %) with a refractometer has been described as highly correlated with IgG concentration in colostrum. The aim of this study was to perform a systematic review on the diagnostic accuracy of the refractometry (measured on a Brix scale) to diagnose good colostrum quality (IgG $\geq 50\text{g/L}$).

Materials and Methods: Systematic review and meta-analysis of the literature were performed using CAB Abstract, Pubmed, Searchable Proceedings on Animal Conferences and Google scholar. Specific estimates of accuracy (sensitivity (Se) and specificity (Sp)) to determine good quality colostrum were obtained for the different reported cut-offs, using the cut-off of 50g/L of IgG measured with radial immunodiffusion (RID) or near infra-red spectrometry (NIRS) as the gold standard. Two by two tables (cross classification based on Brix value ($<$ or \geq Brix cut-off) and the gold standard result ($<$ or $\geq 50\text{g/L}$)) were retrieved or generated; they reported true positive, false positive, false negative and true negative cases. The prevalence of good quality colostrum was also identified or calculated. The internal and external validity of the studies were assessed using the QUALity of Diagnostic Accuracy Study tool (QUADAS2) used in human medicine. The hierarchical summary receiver operating characteristic curve model (HSROC) was used. Stochastic modeling was performed to predict the impact of meta-analysis findings on the probability of diagnosing good colostrum according to the cut-off value that was chosen and the results that were obtained.

Results: From 101 references initially obtained, 11 were included in the systematic review meta-analysis representing a total of 4251 colostrum samples. The prevalence of good quality colostrum in the selected studies varied from 67.3% to 92.3% (median 77.9%, mean 78.8%). The quality of the studies was overall good, except that the sampling strategy was not often detailed. For the Brix cut-off of 22% (n=8 studies), Se was 80.2% (95%CI: 71.1-87.0%) and Sp was 82.6% (71.4-90.0%). Decreasing the cut-off to 18% increased Se (96.1% (91.8-98.2%)) and decreased Sp (54.5 (26.9-79.6%)). Modeling of the impact of Brix accuracy showed that a positive result with the 22% Brix cut-off (ie $\geq 22\%$) can be used to diagnose good colostrum (post-test probability of a having a good colostrum: 94.3% (90.7-96.9%)). The cut-off $<18\%$ could be used to discard poor colostrum with post-test probability of good colostrum estimated at 22.7% (12.3-39.2%).

Conclusions: This systematic review revealed that there was a limited number of available studies-about Brix refractometry accuracy for colostrum quality assessment. Based on this meta-analysis of the literature, 2 cut-offs could be alternatively used to select good colostrum quality (sample with Brix $\geq 22\%$) or to discard poor quality colostrum (sample with Brix $< 18\%$). When sample results are between these 2 values, colostrum supplementation should be implemented.

Effect of Greek oregano oil on the control of neonatal diarrhea in calves

M.A. Karatzia¹, P.D. Katsoulos², E. Papadopoulos³, G. Filiouis⁴, K. Arsenopoulos³, H. Karatzias²

¹Clinic of Farm Animals, School of Veterinary Sciences, Aristotle University of Thessaloniki, ²Clinic of Farm Animals, School of Veterinary Sciences, ³Laboratory of Parasitology and Parasitic Diseases, School of Veterinary Sciences, ⁴Laboratory of Microbiology

and Infectious Diseases, School of Veterinary Sciences, Aristotle University of Thessaloniki, Greece, Thessaloniki, Greece

Objectives: Greek oregano oil yields high contents of carvacrol and thymol. These essential oils are known to possess antimicrobial, antiparasitic, antifungal and antioxidant activities. Based on these properties, oregano oil has been successfully used for controlling diarrhea syndrome in animal species other than calves. Neonatal diarrhea is considered as the most common syndrome occurring in calves under 15 days old and an important cause of financial losses in dairy herds. The objective of this study was to evaluate whether the daily administration of Greek oregano oil is effective in diminishing the severity of calves' neonatal diarrhea syndrome.

Materials and Methods: The study was conducted in a dairy farm with high incidence rate ($>90\%$) of diarrhea syndrome in calves aged less than 10 days old, mainly caused by Rotavirus. The calves of 30 cows vaccinated against Rotavirus, Coronavirus and Enterotoxigenic E. coli that were expected to calve within two months were included in the study. The calves alternately assigned into two groups based on the birth date. The first group (E) consisted of 15 calves that were receiving once daily 12.5 mg/kg Greek oregano oil (Ecodiard liquid 5%) for the first 10 days of their life and the second one (C) of 15 calves that received no treatment and served as controls. After calving, calves of both groups were fed 2 lt of colostrum within 2h. Soon after, the calves of group E were additionally drenched with the respective amount of oregano oil. The drenching was being repeated daily after the morning feeding. During the study period of 15 days, faeces were scored every morning using the following scale: 1=normal, 2=pasty, 3=watery. Fecal samples were obtained from the rectum on days 3, 6 and 10 and on the first day of diarrhea (fecal score, FS ≥ 2) for Cryptosporidium spp. oocysts counts and bacteriological examination. A commercial snap test was also performed with the diarrheic faeces to detect viral agents. The diarrheic calves of both groups were receiving the routine farm treatment. Based on the records, the number of days until recovery (FS=1) were obtained and the average diarrhea fecal score and diarrhea index (FS x days with diarrhea) were calculated. The data were analyzed with SPSS® version 22.

Results: Diarrhea was observed in 27 out of 30 calves used in the experiment. The incidence rate of diarrhea syndrome was unaffected by oregano oil (13/15 and 15/15 for groups E and C, respectively; $P>0.05$). Rotavirus was identified as the causative agent of diarrhea in 11 out of 12 diarrhea cases in group E and in 12 out of 15 cases in group C. The average faecal score throughout the experiment was significantly lower in group E than group C (1.24 \pm 0.063 and 1.52 \pm 0.073 for groups E and C, respectively; $P<0.05$) and on days 8 to 12 of the study ($P<0.05$). The average duration of diarrhea was significantly lower in group E compared to group C (3.08 \pm 0.26 days and 5.13 \pm 0.68 days for groups E and C, respectively; $P<0.05$) as well as the diarrhea index (7.65 \pm 0.68 and 13.54 \pm 1.80 for groups E and C, respectively; $P<0.05$). The average diarrhea faecal score was not significantly different between groups (2.48 \pm 0.09 and 2.60 \pm 0.08 for groups E and C; $P>0.05$). Cryptosporidium spp. oocysts were sporadically identified in low burdens in the faecal smears of the calves.

Conclusions: The administration of Greek oregano oil, on a daily basis, for the first 10 days of the calves' life appeared to be effective in reducing the severity of neonatal diarrhea syndrome caused by Rotavirus.

Study of Haptoglobin Kinetic in Holstein Heifers from birth up to 10 Months of Life

Jean S. Ramos¹Viviani Gomes²Camila C. Martin²Natalia M. Sobreira³Juliana F. Reis²Camila C. Baccili²Karina M. Madureira¹

¹Internal Medicine, Federal University of Bahia, Bahia, ²Internal Medicine, University of São Paulo, São Paulo, ³Autonomous Veterinarian, Araras, Brazil

Objectives: Haptoglobin is an important inflammation biomarker for bovine and can be used in screening for diseases that affect heifers. Thus, the objective of this research was to study the kinetic of haptoglobin (Hp) in healthy Holstein heifers between the first day up to the tenth month of life.

Materials and Methods: For this, 363 Holstein heifers were examined, among which 244 healthy animals were selected. Animals were distributed according to age bracket and divided in 10 groups: 0 - 30 days (M1, n=16), 31 - 60 days (M2, n=15), 61 - 90 days (M3, n=32), 91 - 120 days (M4, n=14), 121 - 150 days (M5, n=35), 151 - 180 days (M6, n=25), 181 - 210 days (M7, n=58), 211 - 240 days (M8, n=12), 241 - 270 days (M9, n=24) and 271 - 300 days (M10, n=13). Blood serum samples were used to determine the concentration of Hp based on the capacity of ligation to meta-hemoglobin molecules, using a control serum with known concentrations of Hp and standard curve prepared in serial dilution. Guaiacol was used as substrate for the reaction. The determination of serum haptoglobin concentration was calculated by linear regression after spectrophotometric determination of absorbance in microplate reader and wavelength 450 nm. Data did not present parametric distribution, thus, medians between moments were compared by Dunn's test. Difference between groups were considered significant when $P < 0.05$.

Results: Medians, minimum and maximum values of haptoglobin (mg/dL) for the different groups were: M1 = 2.45 (1.01 - 5.30); M2 = 1.69 (0.76 - 9.91); M3 = 1.51 (0.64 - 5.60); M4 = 1.58 (0.00 - 9.56); M5 = 3.13 (0.83 - 5.52); M6 = 3.59 (2.50 - 6.11); M7 = 3.78 (0.00 - 5.85); M8 = 3.98 (2.63 - 6.28); M9 = 3.96 (2.54 - 6.44); M10 = 3.85 (2.32 - 5.95). After statistical analysis, it was possible to verify significant difference between M3 group in relation to groups M5 to M10. M4 also presented significant difference when compared to M6, M7 and M9.

Conclusions: It was possible to determine reference ranges and influence of age for Hp in dairy heifers in the first 10 months of life. This is a significant finding for the correct interpretation of the presented values and differentiation of healthy and sick animals.

Effect of Saccharomyces cerevisiae and mannaoligosaccharides on average daily gain and health in Holstein calves under Chilean conditions

Pedro Melendez¹Pablo Pinedo²Maria Paz Marin³Angelica Arias³

¹University of Missouri, Columbia, MO, ²Colorado State University, Fort Collins, CO, United States, ³University Santo Tomas, Vina del Mar, Chile

Objectives: Saccharomyces cerevisiae and its cell wall (glucan and mannan) have been used as an additive in young cattle improving calf growth and performance. These products have not been studied under Chilean conditions; consequently, the objective of this study was to compare the effect of S. cerevisiae, and a β -glucan-mannan based product on average daily gain (ADG) and health of young calves under Chilean conditions.

Materials and Methods: The study was conducted on a dairy farm from central Chile. The farm milked 1,100 cows, producing. At birth, calves were immediately removed from the dam, and fed colostrum according to a standard protocol. Calves were placed in an individual hutch bedded with straw. In order to find a difference of 35 gr on ADG between treated and control groups, with a 95% of confidence and 80% of power, a sample size of 25 calves per group was calculated. A blood sample was obtained between 2 and 8 d of age and serum total protein was measured to monitor passive immune transfer. Calves were fed a milk replacer (21% crude protein, 17% fat) at a concentration of 14.3%, 2 liters, twice a day until 15 days old, and then, 3 liters twice a day until weaning. Starter was pelleted (21% crude protein, 2.5% fat, 11% crude fiber) and was offered with water free choice from 3 days old until weaning. Experimental groups were: G1 = no additives; G2= 3 g/calf/day of mannaoligosaccharides diluted in the milk replacer during the morning feeding (Safmannan®, Lesaffre, France) and G3= 5 g/calf/day of a live yeast culture of Saccharomyces cerevisiae (10×10^9 live cells) diluted in the milk replacer during the morning feeding (Procreatin-7®, Lesaffre, France). Calves were weighed on a scale at 0, 30 and 60 days old before feeding and ADG was calculated. During the study diarrhea and pneumonia events were recorded. ADG was analyzed by ANOVA. Explanatory variables were the treatment, parity of the dam, and calf serum total protein. Incidence of diseases was analyzed through a logistic regression model.

Results: Weaning was carried out at 60 days of life. Body weight at weaning was 71.6 ± 2.5 kg^a, 74.6 ± 2.2 kg^{ab} and 75.9 ± 2.7 kg^b for G1, G2 and G3, respectively ($P < 0.05$). Average daily gain between birth and weaning were 0.56 ± 0.1 kg^a; 0.61 ± 0.11 kg^{ab}; and 0.63 ± 0.1 kg^b for G1, G2 and G3, respectively ($P < 0.05$). Incidences for diarrhea and respiratory diseases in conjunction were 32.3%, 32.4%, and 20.5%, for G1, G2 and G3, respectively. These differences were not statistically significant ($P = 0.21$).

Conclusions: Live yeast culture of Saccharomyces cerevisiae improved significantly average daily gain and tended to decreased diseases occurrences in dairy calves between 0 to 60 days of life managed under Chilean conditions.

Associations of serum amyloid A and haptoglobin with lower weight gain, group size and respiratory disease in dairy calves

Leena Seppä-Lassila¹Jarkko Oksanen²Toomas Orro³Tuomas Herva⁴Timo Soveri¹

¹Department of Production Animal Medicine, University of Helsinki, Helsinki, ²Oulu Environment Office Veterinary Care, Oulu, Finland, ³Institute of veterinary medicine and animal sciences, Estonian University of Life Sciences, Tartu, Estonia, ⁴Atria Ltd, Oulu, Finland

Objectives: The aim of the study was to explore the associations between the acute phase proteins (serum amyloid A and haptoglobin),

group size, respiratory diseases and growth of young dairy calves in calf rearing unit.

Materials and Methods: The study consisted of 480 calves gathered in a calf rearing unit in Northern Finland. A lot of 80 calves, aged 10-35 days, was gathered weekly to the rearing unit. In the trial calves were randomly allocated to control group (LARGE = 40 calves per pen) or experimental group (SMALL = 10 calves per pen, 4 pens) on arrival. The study was repeated for six lots.

SMALL groups were separated from each other and from the LARGE group with solid fences preventing direct contact between calves in different pens. Groups (1 LARGE and 4 SMALL) stayed in one compartment for 80 calves to ensure similar environmental conditions, and shared the air space.

The calves in LARGE and SMALL groups were clinically examined for respiratory diseases, umbilical diseases and diarrhea on arrival, and at 3 and 6 weeks from arrival. Blood samples for haptoglobin, serum amyloid A (SAA) and serology (respiratory syncytial virus, parainfluenza 3 virus, bovine adenovirus and Mycoplasma bovis) were obtained at all clinical examinations. Calves were weighed on arrival to rearing unit and when moved to another compartment after the initial rearing period of 49 ± 5 days, 0-16 days after the third examination.

The workers of the farm followed the calves between the clinical examinations. Calves with respiratory tract disease received antimicrobial treatment if they had body temperature ≥ 40.0 °C or respiratory rate > 60 /min.

Associations between the variables were explored using linear mixed models, lot and pen inserted as random factors. The model was also adjusted for repeated measurements.

Results: Increased serum amyloid A concentrations in calves at the beginning of rearing period (first sampling time) were associated with lower weight gain during rearing period (approximately 50 days). Calves treated for respiratory diseases at the third sampling time had higher SAA and Hp concentrations at the same sampling. Calves from smaller group size had higher SAA concentrations (SMALL 53.0 ± 36.6 mg/l, LARGE 49.2 ± 388.3 mg/l) and higher Hp concentrations (SMALL 285.8 ± 301.7 mg/l, LARGE 264.5 ± 281.5 mg/l) at the end of rearing period (=third sampling time).

Conclusions: The study detected an association between increased SAA concentration and lower weight gain on following weeks, similarly to our earlier results in beef calves (Seppä-Lassila et al, submitted) and reindeer calves (Orro et al 2006). The mechanisms for this phenomenon are yet to discover, but it seems that events affecting immature immune system can have long lasting effects.

Acute phase proteins are seen as markers of inflammation and stress. The general consensus exists that smaller groups would benefit calf health and create a less stressful environment. The results concerning group size in the current study warrant for further studies.

P04-004-142

Time of milk replacer introduction: its effects on pre and post weaning growth.

John Barry^{1,2}, John Paul Murphy², Eddie Bokkers¹, Emer Kennedy²

¹Wageningen UR Livestock Research, Wageningen University PO Box 338, 6700 AH, Wageningen, Netherlands, ²Animal & Grassland

Research and Innovation Centre, Teagasc, Moorepark, Fermoy, Co Cork, Ireland

Objectives: Early introduction of milk replacer (MR) feeding could be a future strategy used to reduce transmission of Johnes Diseases to neonatal calves. The aim of this experiment was to investigate the effect of the timing of introducing MR into the diet of dairy heifer calves on body weight (BW) during the pre- and post-weaning periods.

Materials and Methods: The experiment was carried out at Teagasc, Animal and Grassland Research and Innovation Centre, Moorepark, Fermoy, Co.Cork, Ireland. A study population of 120 dairy heifer calves (Holstein Friesian and Holstein Friesian x Jersey) was used. Calves were weighed immediately after birth (mean BW at birth 33.2 (S.D 3.34) kg) and received 8.5 % of their birth BW in colostrum, obtained from the first milking of the dam within two hours of birth, and was fed via oesophageal tube. Calves were then randomly assigned to one of three treatment groups: (i) fed milk replacer at the feed following colostrum feeding (MR), (ii) fed milk replacer following colostrum feeding and four feeds of transition milk (TM) and (iii) fed milk replacer following colostrum feeding, four feeds of transition milk and ten feeds of whole milk (WM). Milk replacer (26 % crude protein) was fed at a rate of 15 % of birth BW and prepared at 15 % concentration. Weight recording was carried out weekly from birth to weaning to monitor the effect of the treatments on BW. Calves were weaned when they reached 18 % of mature BW and the age at weaning was recorded. Post-weaning, weight was recorded at two week intervals.

Results: There was no difference in BW at birth (33.2 kg) or at weaning (93.2 kg) between the three treatments. There was also no difference in the time taken to reach target weaning weight (90.2 days), and consequently no difference in average daily gain (ADG) from birth to weaning (0.66 kg/day) between treatments. When calves were weighed at 140 and 240 days old again there was no difference in BW (129 and 215 kg, respectively). Similarly there was no difference in ADG from birth to 240 days old (0.75 kg/day) and weaning to 240 days old (0.81 kg/day) between treatments.

Conclusions: Early introduction of MR feeding did not affect BW or ADG of dairy heifer calves in the pre- and post-weaning period. This suggests that milk replacer can be offered to calves immediately after colostrum feeding where there is a risk of Johnes disease transmission to neonatal calves, however colostrum feeding needs to adhere to best practice.

Changes in neonatal beef calf blood chemistry during the first 72 hours of life

Jill M. Larson^{1,2}, Brian L. Vander Ley², Katlyn N. Niederecker¹, Meera C. Heller³, Allison Meyer¹

¹Division of Animal Sciences, ²Department of Veterinary Medicine and Surgery, University of Missouri, Columbia, Missouri, ³Department of Veterinary Medicine and Epidemiology, University of California-Davis, Davis, California, United States

Objectives: The objective of Experiment 1 was to investigate the effect of age on serum chemistry panel measures in suckling neonatal beef calves during the first 72 hours. The objective of Experiment 2 was to determine the effect of maternal forage system during late gestation on neonatal calf serum chemistry.

Materials and Methods: In Experiment 1, a total of 66 fall-calving beef cows and heifers were monitored during calving, and calf blood samples were obtained from a subset ($n = 24$; average dam age = 4.4 ± 0.5 years; average dam BCS = 5.2 ± 0.1 ; average calving date = September 11, 2015). Jugular blood samples were obtained from 8 bull and 16 heifer calves at 0, 6, 12, 24, 48, and 72 hours postnatally for determination of serum chemistry profile. Samples at 0 hour were obtained prior to colostrum intake but after standing. Cow-calf pairs were managed together in large pens, and calves were allowed to suckle normally. Data were analyzed using sampling hour as a fixed effect, and least square means were compared to adult bovine reference ranges used by the University of Missouri Veterinary Medicine Diagnostic Laboratory. In Experiment 2, 56 multiparous, spring-calving crossbred beef cows either strip-grazed stockpiled growth of tall fescue (High quality forage; 12.4% crude protein, 64.1% in vitro total digestibility, dry matter basis; $n = 4$ pastures) or consumed summer-baled tall fescue hay (Low quality forage; 7.6% crude protein, 57.7% in vitro total digestibility, dry matter basis; $n = 4$ uncovered drylots) beginning on day 188 ± 2 of gestation. At 52 ± 0.6 hours of age, calf jugular blood samples were obtained for determination of serum chemistry profile. Data were analyzed using forage system as a fixed effect; calf date of birth and sex were included in the model when $P < 0.25$. Pasture or drylot was the experimental unit. $P \leq 0.05$ was considered to be significant in both experiments.

Results: In Experiment 1, all serum chemistry measures except bicarbonate were affected by sampling hour ($P \leq 0.001$). Serum glucose, urea nitrogen, total protein, and globulin concentrations of neonatal beef calves increased from 0 to 24 hours, then leveled. Concentrations of magnesium, total and direct bilirubin, aspartate aminotransferase (AST), gamma-glutamyl transpeptidase (GGT), and creatine kinase (CK) increased during the first 12 hours, then decreased from 24 to 72 hours of age. Serum creatinine decreased from 0 to 72 hours, whereas serum albumin, calcium, and anion gap decreased during the first 24 hours. Phosphorus and potassium concentrations decreased from 0 to 6 hours, but increased from 24 to 48 hours. Serum sodium and chloride had only slight changes from 0 to 72 hours of age. At some sampling hours, mean glucose, albumin, total protein, globulin, AST, and CK were below their reference range. Mean glucose, creatinine, potassium, chloride, calcium, phosphorus, magnesium, anion gap, total bilirubin, direct bilirubin, GGT, and CK were also above their references range at specific sampling hours. Urea nitrogen and sodium were within their reference ranges for all sampling hours. In Experiment 2, calf birth weight tended to be 10% less for calves born to cows fed low quality forage during late gestation ($P = 0.08$), indicating reduced fetal growth. Calves born to cows fed high quality forage had increased serum creatinine ($P = 0.05$) and albumin ($P = 0.04$) at 52 hours of age; other neonatal serum chemistry measures were not affected by forage system ($P > 0.05$).

Conclusions: Serum chemistry profiles of suckling, neonatal beef calves are impacted by sampling time, which should be taken into consideration when evaluating individual animals. Several measures also may be outside of adult bovine normal references ranges used in many clinical settings, suggesting that neonatal calves need specific reference ranges based on age. Additionally, maternal nutrient intake during late gestation may affect serum chemistry of neonatal calves, even at 52 hours of age.

P04-004-144

Intestinal villi integrity with supplementation of *Saccharomyces cerevisiae* fermentation products in neonate calves with cryptosporidiosis

Sonia Vazquez¹, María D. J. Guerrero², Kristy Dorton³, Mark Scott⁴, Paola Aranda², Carolina Guizar¹, Ana P. Baños-Quintana¹

¹ESIABA, Tecnológico de Monterrey, ²Facultad de Ciencias Naturales, Universidad Autónoma de Querétaro, Querétaro, Mexico, ³Compliance and Regulatory Technical Support, ⁴Diamond V, Iowa, United States

Objectives: The main objective of the study was to characterize the integrity of intestinal villi in neonatal calves naturally infected with *Cryptosporidium* spp. subjected to a daily supplement of *Saccharomyces cerevisiae* fermentation product for 28 days. This study is part of a larger investigation on oocyst shedding and quantitation in dairy female and bull calves treated with the described products.

Materials and Methods: The study took place in a dairy of 1, 100 cows in production in Querétaro, México. 15 dairy bull calves were removed from the calving pens and randomly assigned to their individual hutches receiving one of three treatments: *Saccharomyces cerevisiae* fermentation products (T1); a commercial supplement with mananoligosaccharides (MOS) and yeast (T2); and maltodextrin as control. Treatments were delivered in colostrum, milk and pre-starter for 28 days. At the end of the neonate period all calves were humanly sacrificed at the University premises. Samples from rumen, abomasum, duodenum, jejunum and ileum were taken for histopathology analysis. Slides were stained with hematoxylin-eosin (HE) and measurements were performed in a Carl Zeiss microscope with the Zen system, reading and recording images at 40 X (10 fields per calf). Intestinal villi were classified to assess integrity in total number, normal, disrupted, atrophied and blunt. Intestinal height, width and crypt size were also measured. Sampling for *Cryptosporidium* spp. oocysts took place at 0, 7, 10, 14 and 28 day old calves, quantified with a modified Sheather's technique by Arrowood. Statistical analysis was performed on JMP 11.0.0 (license N15DC1JJ0R). For height, width and crypt size, as well as for intestinal villi integrity with parametric analysis such as Hsu's MCB (multiple comparisons for Best) and Wilcoxon test for non-parametric analysis.

Results: The number of villi in each field varied from 10.1 to 12.5 per campus. When comparing the total number of villi for field groups T1 and T2 for ileum were different to C (p -value < 0.05). Regarding duodenum, scores were similar for all treatments. In case of jejunum, disrupted villi were less in case of treatments T1 compared to T2 and C (p -value < 0.05); atrophied villi were more in T2 and C when compared with T1 (p -value < 0.05); T1 had more normal villi when compared to T2 (p -value < 0.05) and control (p -value < 0.0002). In the case of ileum, total villi were more for T1 (p -value < 0.05); T2 showed more for blunt villi (p -value < 0.02); regarding normal villi T1 showed more than T2 (p -value < 0.0008) and with C (p -value < 0.02). In case of width, height and crypts of intestinal villi the main differences were: in duodenum T1 were wider than T2 and C (p -value > 0.02) while T1 were higher than T2 and C (p -value < 0.0001) with Hsu's MCB and Wilcoxon tests. For jejunum T1 and C were wider than T2 (p -value < 0.0001) with Hsu's MCB and Wilcoxon tests. Crypts in jejunum were T2 different to T1 and C (p -value < 0.0001) with Hsu's MCB and Wilcoxon tests. For ileum T1 and T2 were different from C in height (p -value < 0.0001) with Hsu's MCB and Wilcoxon tests and width (p -value < 0.01). 100% of the bull calves showed *Cryptosporidium* spp. oocysts from 80×10^3 to $4,040 \times 10^6$ in at least two of the five samplings.

Conclusions: Treatment with the *Saccharomyces cerevisiae* fermentation product showed higher numbers of total intestinal villi per field, as well as more normal villi in case of jejunum and ileum. Duodenum, jejunum and ileum villi were wider and higher with the studied treatment. Intestinal villi integrity, and particularly ileum, where it is reported that *Cryptosporidium* spp. causes severe damage, regardless of the prevalence and number of oocysts, was better in case of the bull calves treated with *Saccharomyces cerevisiae* fermentation. The product shows promising results as a villi defender against *Cryptosporidium* spp.

Comments: Commercial names were taken out of the document T1 is Smartcare and Diamond V XPC, T2 is Biomos and T2 maltodextrin.

Associations between average daily gain and calf health, feeding, and management practices in preweaned dairy heifer calves in the U.S.

Chelsey Shivley^{1*} Jason Lombard² Natalie Urie³ Susan Kerr⁴ Amber Itle⁵ Charles Fossler²

¹Department of Animal Sciences, Colorado State University,

²USDA:APHIS:VS, Center for Epidemiology and Animal Health,

³College of Veterinary Medicine and Biomedical Sciences, Colorado

State University, Fort Collins, CO, ⁴Northwestern Research and

Extension Center, Washington State University, Mount Vernon, WA,

⁵Animal Services Division, Washington State Department of Agriculture, Olympia, WA, United States

Objectives: Preweaned dairy calves are traditionally fed lower amounts of milk compared to their beef counterparts. Feeding less milk or milk replacer is associated with lower average daily gains (ADG) and may also lead to increased morbidity and mortality. The objective of this study was to evaluate associations between average daily gain and calf health, feeding, and management practices in preweaned dairy heifer calves in the U.S.

Materials and Methods: This longitudinal study was conducted as part of the National Animal Health Monitoring System's (NAHMS) Dairy 2014 study from March 2014 through August 2015. This study focused on dairy heifer calf health and management from birth to weaning. During the preweaning period for enrolled calves, all health events were recorded and calf growth was assessed at 2-week intervals. Liquid diets were categorized by type (i.e., milk replacer, waste/whole milk, or a combination) and by volume (i.e., > 5.8 kg/day or ≤ 5.8 kg/day). Proc Mixed in SAS was used to determine which diet, health and management practices were significantly associated with ADG ($p < 0.05$). This interim analysis is based on 1,541 calves from 97 operations (approximately 60% of the expected total). A network analysis will be conducted to determine the most important factors impacting ADG, and results will be presented.

Results: A total of 104 dairy operations in 13 states participated, with an average of 24 calves enrolled per operation. The average ADG was 0.7 kg/day (range: 0.08-1.89 kg/day). The average age at weaning was 62.6 days or 8.9 weeks (range: 31-193 days). Calves, on average, gained 47.7 kg during the preweaning period. The average amount of liquid fed per day was 5.8 kg. Whole/waste milk was fed to 38.0% of calves, milk replacer to 36.1%, and a combination of the two was fed to 25.9% of calves. The preliminary model estimating ADG included disease event, liquid diet, season, and the interaction between diet and season. Calves without disease had a higher ADG than calves with one or more disease event. There was a complex interaction between diet, season, and ADG. Further analysis will be conducted to help explain the relationship.

Conclusions: Preliminary results show improved ADG in calves not experiencing a morbidity event. The relationship between ADG, season, and liquid diet will be further evaluated with a complete dataset. Growth in preweaned heifer calves is complex and affected by multiple facets of calf management, which can be modified to improve calf growth and reduce disease occurrence. Improving growth through reduction of disease occurrence can improve animal welfare and decrease the need for antibiotics.

Glossitis indurativa diffusa et chronica caused by the pasture of bamboo

Rudiger Daniel Ollhoff^{1*} Alan J. Ferreira¹ Grassiele Gassenferth

¹Alesson Rodrigo Bueno Debas²

¹Pontifícia Universidade Católica do Paraná, ²Pontifícia Universidade

Catolica do Parana, Curitiba, Brazil

Objectives: The mouth and especial the tongue is for the differential diagnosis of several severe infectious diseases of special importance. Several deaths in post weaning young stock beef cattle were observed after periods inanition and ingestion of bamboo. The objective is to report a case of chronic traumatic glossitis in a heifer.

Materials and Methods: A 10 months old crossbred (Angus x Nelore) heifer was attended at the university Hospital (UHAF/PUCPR - Pontifícia Universidade Católica do Paraná) belonging to an extensive raising beef cattle farm in the county of Fazenda Rio Grande - Paraná State. On bad managed pasture causing hunger several animals were reported grazing nearby native bamboo. Reported inanition in the winter months caused deaths in former years. Ingestion of bamboo and similar symptoms as the reported case were observed. The farm was inspected and the native bamboo called "taquara or cara" was identified belonging to the genus *Merostachys* spp.

Results: The heifer was chronically underdeveloped, cachectic weighing 124,5 kg with disproportional development of the head and body. The hair was dull, the rumen empty and the mandibular lymph nodes slightly increased. The inspection of the oral cavity revealed several scars at the tip of the tongue, that assumed a small balloon like aspect, with the thicker end at the tip. The tongue was firm and painful at palpation, with nearly no mobility. At the proximal lateral region of both sides of the tongue fresh small ulcers were noted, caused by sharp teeth points due to irregular abrasion of the molars. The heifer had extreme difficulty to apprehend the food (TMR) offered. Other clinical parameters were in the normal range. Diagnosis was a diffuse chronic glossitis caused by the ingestion of bamboo and infection of ubiquitous oral bacteria causing cachexy. Treatment was instituted with correction of the teeth followed by 1 oral application of gentiana violet. Glossitis treatment was instituted with phenylbutazone (9 mg/kg IV/SID once and 4,5 mg/kg IV SID-4 days), high dosage of penicilline (35000 IU/kg for 15 days associated with IV-Lugol(Götze)solution - 3 applications in intervals of 1 week. After 3 days of treatment ingestion of ration improved and after 5 days swelling of the tongue decreased allowing better feeding behaviour. At the end of the treatment the tongue improved mobility and consistency. Then the heifers weight was 149,5 kg. For observance of possible recidivance and education purpose the animal was maintained for another month and left the hospital weighing 196 kg.

Conclusions: To our knowledge this is the first report of famine with consequent ingestion of bamboo (*Merostachys* spp.) causing chronic glossitis. Other tropical areas where different bamboo species occur might be alerted that the very splintery material could cause severe lesions to the oral cavity. Complete clinical reversion of chronic indurative glossitis with the instituted treatment was not possible, but survival was guaranteed.

**Innovation.

An evaluation of pathogens and risk factors associated with neonatal enteritis in calves

Michael W. Reynolds BVM&S DCHP MRCVS^{1,*}

¹Livestock Veterinary Teaching & Research Unit, University of Sydney, Camden, NSW, Australia

Objectives: The study had two objectives:

1) An evaluation of the cumulative incidence of neonatal enteritis (based on farmer treatment records), associated cumulative mortality (based on British Cattle movement Services (BCMS) data) and pathogens associated with neonatal enteritis on a subset of practice farms.

2) An examination of risk factors associated with the cumulative incidence of neonatal enteritis and its associated cumulative mortality on a subset of practice farms.

Materials and Methods: 47 dairy and beef farms, with a UK wide distribution and from a single Veterinary practice contributed data to the study.

Information on calf management practices and client perception of the incidence of neonatal enteritis and mortality within the first three weeks of life, were gathered in a quantitative fashion, through the development and distribution of a questionnaire (Boynton and Greenhalgh 2004).

Client questionnaires were not anonymous, with all respondents identified by both personal and farm names. This allowed correlation of client perception of the incidence of neonatal enteritis and neonatal calf mortality within the first three weeks of life to be paired against actual disease incidence and mortality rates on farm.

Surveillance for enteric pathogens was undertaken when a diagnosis of neonatal enteritis was made by the attending veterinarian, either during routine calf health monitoring or sick calf visits, utilizing the validated "Cow-side ELISA" Scour Check Rapid™ (MSD Animal Health), to test for a fixed group of major pathogens associated with neonatal enteritis (Rotavirus, Coronavirus, E.coli F5 (K99), Cryptosporidium parvum).

Data from returned questionnaires was collated into the study database (Microsoft Office Excel, 2007 Microsoft Corp) and statistical analysis performed using Epi-Info version 3.5.4 (CDC) statistical software.

Results: Data analysis revealed a mean neonatal enteritis cumulative incidence of 26% (95% CI=18.11 to 33.89) across the studied farms, determined from farmer treatment records and the mean cumulative mortality to be 4.5% (95% CI= 2.65 to 6.35) as determined from BCMS data.

Rotavirus was the most prevalent pathogen found, with 70% of calves tested showing exposure (n=35). Cryptosporidium parvum was the second most common pathogen accounting for 40% (n=20) of infections. Of the calves sampled, 40% had combined Rotavirus and Cyptosporidium parvum infections (n=20).

Analysis of BCMS data revealed a significant association in terms of higher neonatal calf cumulative mortality in the first twenty one days of life in those herds relying on self feeding from dam, compared to those actively administering colostrum to newborn animals (RR= 2.83, 95% CI= 1.01 to 7.91, p=0.045 Fishers Exact test).

Analysis of BCMS data showed a significant association between those herds utilizing dedicated youngstock staffing and a reduced neonatal calf cumulative mortality within the first twenty one days of life (RR= 2.5, 95% CI= 1.25 to 5.01, p=0.001 Fishers Exact test).

Analysis of BCMS data showed a significant association between the presence of circulating BVD virus and an increased neonatal calf

cumulative mortality within the first twenty one days of life (RR= 0.30, 95% CI= 0.08 to 1.13, p=0.04 Fishers Exact Test).

Farmer perception bore NO relationship to the actual cumulative incidence of neonatal enteritis experienced on farm.

Conclusions: Within this study the reliance upon self-feeding from the dam as the sole means of passive transfer, the employment of dedicated youngstock staff and the presence of circulating BVDV were all found to have a significant association with neonatal calf cumulative mortality in the first twenty one days of life.

These factors compounded by the finding of farmer perception bearing NO relationship to the actual cumulative incidence of neonatal enteritis experienced on farm may warrant further investigation using a larger dataset and may serve as factors for consideration in future youngstock health audits and knowledge transfer programs.

Blood transfusion in young calves in case of illness

Ksenija Perse Sajovic¹ Tomaz Cigler^{1,*} Mitija Sajovic¹

¹Veterinarska postaja Brestanica, Brestanica, Slovenia

Objectives: Blood transfusion in cases of weak calves is something so beneficial that we can choose to describe it as good, very good or even... spectacular! Since there is little said about that topic in literature, we decided to sum up our experience.

Materials and Methods: We often find calves in their first days or weeks of life which are very weak, either from birth, or following some kind of illness. Sometimes calves lack colostrum, making them much more susceptible to disease. But even if they are fed the best colostrum they may still end up septic, causing them to dehydrate rapidly as they have very little body reserves. Diarrhoea and pneumonia, caused by viruses or bacteria, appear constantly among young calves.

We have also cases where calves remain weak despite therapy. Anaemia coupled with an insufficient immune response brings the whole organism close to death again. In such a situation we attempt blood transfusion. With it we support the calf's natural defense systems in combat against intruders (viruses, bacteria). In cases where we have a certain degree of dehydration, we also maintain a better fluid supply. If a calf needs a transfusion, it needs a transfusion – or it will die. So it is worth a try. All we need is a collecting bag, commercially available. For example, human disposable bags, which can collect up to 450 ml. In such cases (more often in dairy herds, where we have abandoned calves, which value very little in money), long or prolonged treatment is not acceptable for the farmer. That is a sad fact, but we can do little against it. The drug industry doesn't support research in this field because they have no interest in these procedures. Due to the fact that the "drug" is not something to sell, but is just solid, crude tissue, real blood, taken out of the body on site. So far, it's for free.

Results: The donor cow should preferably be its mother. If the mother is not available, we can use another cow from the herd. We have not had bad experiences with anaphylaxis, even if the treatment was repeated twice. The main focus is adding more antibodies from a healthy cow directly to the calf. To take blood from the cow we need blood bag. The amount of blood in one bag is appropriate for a young calf weighing from 40 to 100 kg. After administrating the needle into the abdominal vein (in dairy cattle this is not difficult) it takes about 10 minutes to collect a full bag. Gently agitate

the collected blood to mix it with the anticoagulant solution. Once the bag is full, run a small amount out of the line onto the ground to prevent blood clotting in the line or needle. The calf is then restrained (often it is too weak to fight back). The area of the jugular vein is clipped and an IV catheter or needle is placed. We then attach the blood bag to the needle and give the calf blood. A bag could be emptied in 10 to 15 minutes without risk to the recipient. Within several hours the calf will often stand up and start drinking on its own. It's rare that a calf needs a second transfusion. It can drastically help the organism if it is done early enough in the disease process. Another benefit of this type of procedure is that the blood is always at the proper temperature for transfusion since only a few minutes pass between taking the blood from the donor and giving it to the calf. The benefit of this is not to be ignored, as many calves that require a transfusion are already hypothermic.

Conclusions: Blood transfusion can be done in field conditions easily and is performed as an emergency life-saving procedure. It costs very little, especially in comparison with the excellent benefits it brings. It is worth doing from a welfare and treatment aspect. The procedure is also very satisfying for veterinarians and farmer clients. In our veterinary practice, VPB, we started years ago in cases where nothing else could be done. This "ultima ratio" experiment gave us an example of good and successful practice with a herd of saved cases. Give it a try!

P04-004-151

Bacterial count in frozen spare supply of colostrum on 42 dairy farms around Someren (Netherlands)

Jan Hulsen¹;Niels Groot Nibbelink²Dré Delhij³

¹Vetvice - CowSignals, Bergen op Zoom, ²Veterinary Center Someren, Someren, ³HAS University of Applied Sciences, Den Bosch, Netherlands

Objectives: The bacterial count is besides the concentration of antibodies, most specifically IgG, the most important component of colostrum quality (Stewart et al., 2005; Godden, 2008). An increased bacterial count has a negative effect on the absorption of IgG in the intestinal tract of the newborn calf (Langel et al., 2015). The upper limit of bacterial counts in milk and colostrum is generally defined as 100.000 cfu/ml (i.e. Morrill et al., 2012).

The goal of this study was to analyze the bacterial count and coliform count of frozen spare supply of colostrum on 42 dairy farms, all clients of Veterinary Center Someren.

Materials and Methods: On 42 dairy farms that were clients of Veterinary Centre Someren, 95 samples were aseptically taken from frozen colostrum that serves as spare supply to be fed as a first meal to newborn calves when there is no colostrum from the own dam available. At the moment the farmers put the colostrum in the freezer, they did not know about this study.

The samples were transported in cool boxes and arrived in frozen condition at the laboratory of VC Someren, that performed bacterial counts. The results of 11 samples were not used because these samples were not representative: the farmers had handled and frozen this colostrum in a different way than they normally would have done.

In 64 of the samples also the coliform count was analyzed. In the first batch of 20 samples this test was not performed.

Results: 58% (49 of 84) samples had a bacterial count higher than 100.000 cfu/ml and 10% had a bacterial count higher than 100.000.000 cfu/ml.

17% (12 of 64) samples had a coliform count higher than 10.000 cfu/ml.

Dairy farmers in this area keep a spare supply of frozen colostrum to feed to newborn calves in cases that there is no or not enough fresh colostrum available. This colostrum is mosttimes used in cases there is no or not enough fresh colostrum available for a newborn calf.

It is assumable that the bacterial count will further increase during the process of thawing, handling and feeding this colostrum.

Conclusions: 58% of the 84 sampled portions of refrigerated colostrum stored on 42 dairy farms around Someren (NL) had a bacterial count higher than the internationally maximum standard of 100.000 cfu/ml.

17% of 62 sampled portions had a coliform count higher than the international maximum standard of 10.000 cfu/ml.

Comments: The process of selection plus the number of dairy farms make it highly assumable that the results are a reliable reflection of the situation amongst all the clients of this veterinary practice. There are no reasons to assume that this group of dairy farmers is not representative for the whole dairy farmers population in at least the south of the Netherlands.

Bacterial count in the first meal of colostrum at the moment of feeding on 17 dairy farms around Someren (Netherlands)

Jan Hulsen¹;Niels Groot Nibbelink²Jens Verheijen³

¹Vetvice - CowSignals, Bergen op Zoom, ²Veterinary Center Someren, Someren, ³HAS University of Applied Sciences, Den Bosch, Netherlands

Objectives: The bacterial count is besides the concentration of antibodies, most specifically IgG, an important component of colostrum quality (Stewart et al., 2005; Godden, 2008). An increased bacterial count has a negative effect on the absorption of IgG in the intestinal tract of the newborn calf (Langel et al., 2015). The upper limit of bacterial counts in milk and colostrum is generally defined as 100.000 cfu/ml (i.e. Morrill et al., 2012).

The goal of this study was to analyze the bacterial and coliform count of colostrum at the moment it is fed as first, second or third meal to newborn calves dairy farms, all clients of Veterinary Center Someren.

Materials and Methods: Samples were taken by dairy farmers, who had received sampling instructions on a chart and a sample kit.

A normal operating procedure after calving is to milk out the dam completely and feed the first colostrum to the calves in separate meals, until it is finished. Then the calve receives meals with colostrum from a second or later milkings.

The sample kit consisted of 5 sterile 5 ml disposable syringes with a sterile 1.2 mm x 3.5 mm (pink) needle, plus 10 milkers gloves. Instruction was to aspirate colostrum into the syringe via the needle and immediately put the syringe plus covered needle into a refrigerator. During the sampling period the farmers were aware of the results of an earlier studie of the bacterial count of frozen colostrum supply on dairy

farms, in which 58% of the samples exceeded the maximum bacterial count of 100.000 cfu/ml.

The samples were collected, transported in a cool box and arrived in frozen condition at the laboratory of VC Someren, that performed bacterial counts. On 17 dairy farms 86 samples were taken and analysed. 6 samples were not used in the analysis, because they were not taken from first colostrum or the colostrum was not handled in the normal way by the farmer.

Results: 24% (17 of 70) of the samples of the first colostrum meal had a bacterial count higher than 100.000 cfu/ml and 7% (5 of 70) had a coliform count higher than 10.000 cfu/ml.

30% (3 of 10) of the samples of the second colostrum meal had a bacterial count higher than 100.000 cfu/ml and 10% (1 of 10) had a coliform count higher than 10.000 cfu/ml.

The number of samples of second colostrum meals is too low for significant conclusions. It can be assumed that the bacterial count and coliform count will increase over time in many cases, as very few farms were quickly refrigerating the remaining part of the colostrum.

Conclusions: 24% (17 of 70) of the samples of the first colostrum meal had a bacterial count higher than 100.000 cfu/ml and 7% (5 of 70) had a coliform count higher than 10.000 cfu/ml.

In practice, a substantial part of colostrum that is given as a first meal to newborn calves has a too high bacterial count.

Comments: Most of the practical work in this study was performed by Jens Verheijen.

for the WBC abstract committee: In the Dutch magazine Tijdschrift voor Diergeneeskunde of the Royal Dutch Veterinary Society KNMvD, Jan Hulsen published an article on colostrum that also mentions this study. This article is in Dutch and has no English summary or what so ever. Therefore the authors think it is relevant that this study as such will be published, hopefully at the WBC. To share the info with the whole world and not just with the Dutch veterinarians.

Use of blood gas analysis to assess neonatal calf diarrhea and subsequent recovery with an EC-compliant oral electrolyte solution

Riona Sayers^{1,2}Aideen E. Kennedy¹Gearoid P. Sayers^{3,*}Emer Kennedy⁴

¹Animal & Biosciences, Teagasc, Moorepark, Fermoy, Co. Cork,

²Animal & Biosciences, Teagasc, Moorepark, Fermoy, Co. Cork,

³Tralee Institute of Technology, Co. Kerry, ⁴Livestock Systems, Teagasc, Moorepark, Fermoy, Co. Cork, Ireland

Objectives: Electrolyte disturbance, dehydration and metabolic acidosis, accompanied by a strong ion difference (SID), are the most significant consequences of diarrhea in calves. The aim of this observational study was to firstly investigate outbreaks of calf diarrhea on four dairy farms using blood gas analysis. Secondly the study sought to evaluate treatment of diarrheic calves using an oral rehydration and buffering solution (ORBS) that is compliant with current EU legislation.

Materials and Methods: An observational study was conducted on 77 calves (51 healthy, 31 calves with neonatal diarrhea, 5 calves represented in both groups) during outbreaks of diarrhea on four dairy

farms in Ireland. All animals were clinically assessed and scored (CAS) (0= healthy to 4=marked illness). Blood gas analysis was carried out on all animals, with repeated measurements taken in healthy animals, and pre- and post-intervention measurements taken for diarrheic calves. A bench top Rapidpoint 400 (Siemens, Munich, Germany) analyser was used to test all samples. Parameters reported by the analyser included, inter alia, pH, base excess (BE; mM), Na⁺ (mM), K⁺ (mM), Ca²⁺ (mM), Cl⁻ (mM), Glucose (mM), total haemoglobin (Hb; g/dL), standard HCO₃⁻ (mM), and anion gap (AG; mM). For healthy calves, samples were taken over a period of three days, approximately two hours post-feeding. In the case of diarrheic calves, pre-treatment samples were taken within two hours of a milk feed being offered. These calves were then administered an ORBS, 'Vitalife for Calves' (Epsilon Ltd., Cork, Ireland) reconstituted in water according to manufacturer instructions. All treatments were administered by stomach tube.

Statistical analyses were completed in Stata version 12 (StataCorp, USA). Correlations between CAS and blood gas parameters were investigated. Associations between various genetic and environmental factors and blood gas measurements were investigated in the healthy calf cohort. A cross-sectional, time series, generalised estimating equation was used to account for repeated measures.

Results: The mean clinical assessment score of diarrheic calves was 1.7, with 51%, 30%, 17% and 2% of calves scoring 1, 2, 3 and 4, respectively. The mean values for blood pH, BE, AG and SID was 7.26, -4.93 mM, 16.3 mM and 38.59 mM, respectively. The mean clinical assessment score at 6 to 18 hours post-treatment with the ORBS was 0.38 (65% of calves scored 0 and 35% scored 1), which reduced to 0.03 (98% of calves scored 0 and 2% scored 1) within 24 to 48 hours. There was a significant increase in mean values (P<0.001) for pH, BE, HCO₃⁻, Na⁺ and SID after treatment, while a significant decrease was recorded for AG, K⁺, Ca²⁺ and total haemoglobin. The correlation estimates indicate that pH, HCO₃⁻ and BE were strongly and significantly correlated with clinical assessment score, with values exceeding 0.70 in all cases (P<0.05).

Conclusions: Administration of an ORBS formulated on a principle of high SID, coupled to a bicarbonate buffer and supplementary nutritional ingredients, demonstrated rapid recovery from a diarrheic episode in dairy calves. Additionally, we observed measurement of blood pH to be a useful and practical tool in monitoring calf recovery following treatment for diarrhea.

P04-004-154

Effect Of The Oral Administration Of Specific Immunoglobulins Compared To Standard Vaccination On Calf Neonatal Enteritis

Arnaud Bolon¹Damien Lebastard²Richard Eicher^{3,*}Serge Carel³

¹Merial, Lyon, ²Vetavenir, Yzernay, France, ³Biokema S.A., Crissier, Switzerland

Objectives: Under pressure to reduce the use of antibiotics in animal production, prevention of disease is getting more and more important. Prevention of neonatal calf enteritis (NCE) is commonly performed by vaccination of pregnant dams against the main pathogens involved in NCE.

The objective of the study was to evaluate the clinical effect of an application of specific immunoglobulins concentrate against different strains of E. coli, Rotavirus and Coronavirus given orally to the calves in

addition to normal colostrum on NCE. This procedure was compared to a standard vaccination of the dam against the same pathogens.

Materials and Methods: Calves were chosen in a commercial dairy herd with a standard management and no previous history of high incidence of NCE. This herd had previously not vaccinated against NCE.

For each group of 10 dry cows, half of them were primo-vaccinated with one dose of ROTAVEC® CORONA between 12 and 3 weeks before calving. Each calf born from non-vaccinated cows received one dose of 60ml of LOCATIM® orally within the first 6 hours of life. Every calf received colostrum of his mother.

For each included calf, the farmer registered the vaccination date or the time of LOCATIM® administration, as well as the clinical scoring of diarrhoea during the first 15 days of life. Diarrhoea score was defined according to following criteria: 0 = no diarrhoea; 1 = light diarrhoea without medical treatment; 2 = important diarrhoea requiring oral treatment (rehydration and/or antibiotic therapy); 3 = severe diarrhoea requiring parenteral rehydration or death.

Statistical analyses were performed with the statistical software SYSTAT 12 for Windows®.

Results: 45 (LOCATIM group) and 43 (ROTAVEC group) calves were included in the study. All ROTAVEC cows were vaccinated between 23 and 79 days before calving. All LOCATIM calves received the oral specific immunoglobulins concentrate between 15 and 120 minutes after birth. There was no association between occurrence of diarrhoea and neither time of vaccination before calving nor time of application of the oral specific immunoglobulins concentrate after birth ($p > 0.35$, Kruskal Wallis test or General Linear Model).

The sum of diarrhoea scores was 9 in the LOCATIM group and 29 in the ROTAVEC group. The difference was statistically significant ($p = 0.002$, Mann-Whitney U-test).

18 calves (41.9%) in the ROTAVEC group and 5 calves (11.1%) of the LOCATIM group showed some form of diarrhoea. The difference was statistically significant ($p = 0.001$, Pearson Chi-square test).

If only severe diarrhoea (scores 2 and 3) was considered, 9 / 34 (26.5%) calves were found in the ROTAVEC group vs 3 / 43 (7.0%) in the LOCATIM group. The difference was statistically significant ($p = 0.027$, Fisher's exact test).

Conclusions: In our study, the oral application of specific immunoglobulins concentrate against NCE was effective. Compared to a well-established vaccination against strains of *E. coli*, Rotavirus and Coronavirus, the occurrence and the severity of calf's diarrhoea were significantly reduced.

The oral solution of specific immunoglobulins concentrate warrants the easy and direct transfer of the specific antibodies. It is an effective and simple alternative to vaccination protocols against neonatal calf enteritis.

Comments: In addition, blood samples for the measurement of the specific IgG against *E. coli* F5 (K99), CS31A, F17 (Att25) and F41 as well as against rotavirus and coronavirus were taken. The results of the analyses will be available in April 2016.

P04-004-155

Bovine respiratory disease monitoring in veal calves: clinical signs predictive of calf pneumonia as diagnosed by ultrasonography

Bart Pardon¹*Pieter De Wolf²Randy Boone³Laura Van Driessche¹Bonnie Valgaeren¹Linde Gille¹Filip Boyen⁴Piet Deprez¹

¹Large Animal Internal Medicine, Ghent University, Merelbeke, ²Veterinary Practice Venhei, ³Veterinary Practice Venhei, Kasterlee, ⁴Department of Pathology, Bacteriology and Avian Diseases, Ghent University, Merelbeke, Belgium

Objectives: A more rational use of antimicrobials for bovine respiratory disease (BRD) would imply only antimicrobial treatment of bacterial infections of the lower respiratory tract and not of the upper airways. Therefore, disease detection systems should monitor symptoms which are predictive of pneumonia and discriminate lower from upper respiratory tract infection. The objective of the present cross-sectional study was to determine which clinical signs are predictive of active pneumonia lesions in 5-8 week old calves, as diagnosed by thoracic ultrasonography.

Materials and Methods: A cross-sectional study was done in two veal farms, determining clinical signs and ultrasonographic findings at the time of a BRD outbreak. Clinical signs were recorded by a single person before the morning feeding. A first set of parameters involved parameters visible from the feeding ally, such as position of head and ears, recumbency, appetite, milk left-overs, nasal and ocular discharge, spontaneous cough and breathing frequency/type. A second set of parameters were collected in a detailed clinical examination (aspect nasal and ocular discharge, ocular mucosae, larynx and trachea reflexes, stridor, sucking reflex, fecal aspect, joint inspection, rectal temperature, heart frequency and trachea + lung auscultation). After recording of the clinical parameters a broncho-alveolar lavage were taken for bacteriological examination. Presence of pneumonia was detected by ultrasonography using a 7.5 MHz linear probe (Mylab One, Esaote Benelux). A calf was considered a pneumonia case when at least one zone of $>1 \text{ cm}^2$ of consolidation was detected. Multivariable logistic regression was used to determine association between the clinical signs and pneumonic lesions and to determine the most sensitive and specific model to predict pneumonia.

Results: Preliminary results on 67 calves are available. In herd 1 40.0% (14/35) and in herd 2 34.4% (11/32) of the calves showed ultrasonographic lesions consistent with pneumonia. In both herds, *Pasteurella multocida* (54.3% in herd 1 and 15.6% in herd 2), *Mannheimia haemolytica sensu lato* (37.1% vs. 6.3%), *Mycoplasma bovis* (42.9% vs. 6.3%) and *Mycoplasma bovirhinis* (22.9% vs. 53.1%) could be isolated from BAL samples. *Histophilus somni* was detected in only 1 calf (herd 1). Clinical signs, univariably associated with pneumonia were breathing frequency ($P=0.05$), lowered head carriage (sign of depression) ($P=0.03$), and pale ocular mucosae ($P=0.04$). The most sensitive final model consisted of breathing frequency (OR= 1.5 (1.1-2.1); $P= 0.02$) for each increase by 10 breaths in a minute) and head position (OR of a lowered head= 3.5 (1.1-11.4); $P= 0.03$). This model had a sensitivity and specificity of 92.7% and 36.0%, respectively and classified 71.2% of the calves correct.

Conclusions: In conclusion, these preliminary results show that few clinical signs can distinguish pneumonia from upper respiratory tract infection in an outbreak situation. Frequently monitored signs such as fever and cough are not among these. A simple model focusing on breathing frequency and head position was most sensitive to detect calves with ultrasonographically visible pneumonia lesions, but resulted in many false positives. Further model building and validation is required to confirm this model.

P04-004-156

Associations between passive immunity and health status for Irish dairy and suckler beef calves

Cynthia Todd¹, Katie Tiernan^{1,2,3}, Mark McGee², Paul Crosson², Ingrid Lorenz³, Bernadette Earley¹

¹Animal and Bioscience Research Department, ²Livestock Systems Research Department, AGRIC, Teagasc, Grange, Dunsany, Co. Meath, ³School of Veterinary Medicine, University College Dublin, Belfield, Dublin 4, Co. Dublin, Ireland

Objectives: There is a need for information about the passive immune status of calves on commercial dairy and suckler beef farms in Ireland. Hence, the objectives of this study were to: 1) investigate levels of passive immunity in Irish dairy and suckler beef calves and 2) evaluate associations between passive immunity and calf health from birth until 3 months of age.

Materials and Methods: A total of 84 dairy and 111 suckler beef farms throughout Ireland were visited during the autumn 2014 and spring 2015 calving seasons. Blood samples were collected by jugular venipuncture from 1040 dairy and 923 suckler calves between 1 and 21 days of age. Serum was harvested and the Zinc Sulphate Turbidity (ZST) test, which indirectly measures immunoglobulin levels, was performed. ZST results were categorized as follows: LOW (L) = '<10', MEDIUM (M) = '10-20' and HIGH (H) = '>20' units. ZST data were analysed using ordinal logistic regression. Standardised case definitions for disease were provided and farmers were requested to record all disease events. Morbidity was defined as a calf being treated for at least one case of disease between birth and 3 months of age. Morbidity data were obtained for 682 calves from 54 dairy farms and 575 calves from 73 suckler farms. Logistic regression models were constructed to evaluate associations between ZST results and the odds of morbidity.

Results: Mean ZST units for dairy and suckler calves were 18.1 (SD=7.9) and 16.1 (SD=7.4), respectively. Sampling age was significantly associated with ZST status ($P < 0.01$). Dairy calves were less likely to have ZST results in the lower categories than suckler calves (L: 13.9 vs. 21.1%, M: 50.3 vs. 51.0%, H: 35.9 vs. 27.8%, $P < 0.01$). Calves born in spring were more likely to have greater ZST units than autumn-born calves (Dairy – L: 13.0 vs. 19.2%, M: 47.7 vs. 66.7%, 39.3 vs. 14.2%, $P < 0.01$; Suckler – L: 22.8 vs. 16.7%, M: 48.5 vs. 58.1%, H: 28.8 vs. 25.2%, $P = 0.04$). Gender, twin status and colostrum feeding method were not associated with ZST category for dairy or suckler calves. Overall, 16.7% of dairy calves and 25.1% of suckler calves were treated for disease in the first 3 months of life. Calves were most commonly treated for diarrhoea (71.9% of dairy disease events, 29.7% of suckler disease events) or respiratory disease (8.8% of dairy disease events, 25.5% of suckler disease events). The odds of dairy vs. suckler calves being treated for disease were not significantly different (Odds Ratio = 1.6, $P = 0.17$). Suckler calves with LOW ZST units had greater odds of being treated in the first 3 months of life than MEDIUM (Odds Ratio = 2.1, $P = 0.03$) and HIGH ZST suckler calves (Odds Ratio = 2.7, $P = 0.01$). Dairy calves did not significantly differ for morbidity by ZST category ($P = 0.13$).

Conclusions: This is the first large-scale observational study on passive immunity and calf health to be conducted under field conditions in Ireland. These results demonstrate that many Irish calves are at risk of failure of passive transfer of immunity (FPT). A cut-point value of 20 ZST units has traditionally been used to denote FPT. However, recent research has suggested that this cut-point needs to be re-assessed and a value of 11 ZST units was proposed, which would be in line with the LOW ZST category. These results also provide further evidence of a negative relationship between FPT and calf health.

Comments: We acknowledge the DAFM Stimulus Fund (11/S/131) for financial support.

Monitoring of enteropathogens in young calves in South Belgium : assessment of the diagnostic protocol

Julien Evrard¹, Marc Saulmont¹, Fabien Grégoire¹, Jean-Yves Houtain¹

¹ARSIA (Regional Association for Animal Identification and Health), Ciney, Belgium

Objectives: The aim of this study is the assessment of the standard protocol for analysis of fecal samples from young calves currently performed by ARSIA (Regional Association for Animal Identification and Health) and the calculation of the prevalence of major enteropathogens of calves in Southern Belgium. The current protocol is designed to find the following pathogens: *Cryptosporidium parvum*, rotavirus, coronavirus and pathogenic enterobacteria such as *Salmonella* spp., *Klebsiella pneumoniae* and the following potentially pathogenic *Escherichia coli* strains : CS31A, F17a, K99 and Enterohemolysin +.

Materials and Methods: Fecal samples of 236 calves under 1 month of age and with diarrhea from 176 Walloon farms have been analyzed between February 2014 and Mai 2015. For each sample, an associated survey provided informations such as the age of the animal at the sampling time.

The standard protocol includes 2 methods of analysis. ELISA were performed for the *Cryptosporidium parvum*, rotavirus and coronavirus detection. Pathogenic enterobacteria are detected by an aerobic culture on Gassner medium. Then, colonies are identified by MALDI-TOF mass spectrometry (Matrix Assisted Laser Desorption Ionisation, Time of Fly). All isolated *E. coli* are serotyped by 2 methods: (1) culture on Enterohemolysine agar (Enterohemolysine +) and (2) culture on MINCA medium following serotyping with 3 antisera (CS31A, F17a, K99).

Data have been analyzed in two ways: a global approach and an age group approach. Then samples have been divided into 6 age categories: 1-3 days (n = 30), 4-6 days (n = 32), 1 week (n = 107), 2 weeks (n = 40), 3 weeks (n = 17) and 4 weeks (n = 10).

Results: Overall results were satisfactory since at least one pathogen was found in 87.29% of the tested samples. However, in the 1-3 days old group, no pathogen was detected in 50% of those. In 51.27% of fecal samples, more than one pathogen was found (up to 70% in the 2 weeks old group). As results are not ranked, this can complicate the interpretation of the data.

Regardless of the calves age, apparent prevalences are 50.42% (95% CI : 44.04 - 56.80) for *Cryptosporidium parvum*, 9.32% (95% CI : 5.61 - 13.03) for coronavirus, 41.53% (95% CI : 35.24 - 47.82) for rotavirus, 36.02% (95% CI : 29.90 - 42.14) for *E. coli* CS31A, 11.44% (95% CI : 7.38 - 15.5) for *E. coli* F17a, 0.85% (95% CI : 0 - 2.02) for *E. coli* K99 and 2.97% (95% CI : 0.80 - 5.14) for *E. coli* Enterohaemolysine +. No *Salmonella* spp. nor *Klebsiella pneumoniae* was found.

Conclusions: This study highlighted the need to improve the standard protocol of young cattle faeces especially for calves of 3 days and under in which, for 50% of them, no pathogen has been found. This can be due to a non-exhaustive research of possible causes, a lack of sensibility of used tests and/or potential treatment effects. When more than one pathogen is found, it would be efficient to rank the results based on the relative importance of each agent. Although *Salmonella* was expected, this bacteria was not detected. Since its prevalence is low, it is likely that the sample size was too small.

P04-004-158

Association between colostrum, serum natural antibody, hematological parameters, and morbidity in Holstein dairy heifers

Andre Teixeira ¹, Vinicius Machado ², Rodrigo Bicalho ²

¹Animal Science, ²Population Medicine and Diagnostic Sciences, Cornell University, Ithaca, United States

Objectives: The objective of this study was to investigate 3 days old calf serum levels of natural antibodies and its associations with administered colostrum quality (Brix), serum immunoglobulin-G (ELISA), morbidity (incidence of pneumonia, otitis, and diarrhea), mortality, and hematology during the pre-weaning period.

Materials and Methods: Eighty newborn Holstein heifer calves were selected to be part of a prospective cohort study. Colostrum from primiparous cows were pooled and used for the study heifers. All calves were fed 4 L of raw colostrum by esophageal feeder. Colostrum samples for Brix measurements were collected daily 20 minutes before colostrum administration; each calf had a unique Brix measurement relative to the colostrum received.

Twice daily, newborn calves were moved from the newborn pen located in the maternity area to the calf barn. The calf barn was a green-house type of barn, positive ventilated and composed by identical individual-pens (1.5 meter wide by 2 meter long) equally distributed inside the barn. Calves were fed a total of 6 L of pasteurized non-saleable milk divided equally twice a day. Data regarding average daily gain and disease diagnosis were collected by the research group for all study heifers.

Calf pneumonia was defined when two or more of the following clinical signs were detected in a calf: cough, rectal temperature > 39.5°C, respiratory rate > 40 breaths/min, increased cranioventral lung sounds or wheezes. Otitis was defined by observation of ear pain evidenced by head shaking, scratching or rubbing the ears, epiphora, ear droop, and signs of facial nerve paralysis with or without fever > 39.5°C. Following the diagnosis of disease, animals were treated according to the farm protocols.

Blood collection was collected at 3 and 14 days of life. Serum samples were submitted for complete hematology and measurements of IgG and Natural Antibody.

Results: A total of 47 calves born from primiparous and 33 calves born from multiparous were followed from birth until approximately 60 days of life. No significant differences were observed for data collected on calves born from primiparous and multiparous.

A positive correlation was reported between colostrum Brix and serum IgG ($r^2 = 0.45$, $P = 0.001$) and serum NAb ($r^2 = 0.46$, $P = 0.001$) at 3 days of life. Additionally, a very high correlation between serum NAb and serum IgG from 3 days old calves was observed ($r^2 = 0.45$, $P < 0.001$). A critical threshold for serum natural antibody at 3 days of life was determined by a ROC analysis. A threshold value lesser or equal to 0.215 with a 95.24 % sensitivity and 94.92 % specificity detecting calves that had inadequate passive transfer determined by serum immunoglobulin-G (≤ 1000 mg/dl) with an area under the curve (AUC) of 0.986. A significant lower hazard of otitis (HR = 0.55, $P = 0.04$) and CPO calves (HR = 0.45, $P = 0.01$) was reported for calves that had adequate serum levels of natural antibody ($OD_{650} > 0.215$) when compare to calves that did not ($OD_{650} \leq 0.215$).

A receiver-operator characteristic curve was used to determine a critical threshold for Lymphocyte to Monocyte ratio. The cutoff (LMR ≤ 5.67) with a 69.4% Sensitivity and 73.3% Specificity on predicting CPO with an area under the curve (AUC) of 0.718 ($P = 0.008$). A Kaplan Meier survival curve for calves affected with pneumonia and/or otitis was

performed. Calves with low LMR were at 2.53 higher hazard (95%CI: 1.44 – 4.44) of CPO when compared to calves with high LMR.

Conclusions: In this study we suggest a cutoff point of adequate natural antibody levels. Level of serum natural antibody at 3 days of life was significantly associated with colostrum Brix and serum level of IgG. Additionally, calves that had adequate serum level of natural antibody were at a lower hazard of combined events of pneumonia and otitis. There could be more factors in colostrum involved in calf health during the pre-weaning period.

Additionally, for the first time the lymphocyte to monocyte ratio at 14 days of life was reported to be a significant predictor of pneumonia and otitis during the first 60 days of life.

Young Stock

P04-004-159

Implication of Coronavirus in pulmonary lesions in calves

Fabien Grégoire ¹, Maude Lebrun ², Christian Quinet ¹, Cédric Mullender ¹, Marc Saulmont ¹

¹ARSIA (Regional Association for Animal Identification and Health), Ciney, ²MSD Animal Health Belgium, Brussels, Belgium

Objectives: Infectious respiratory disorders in calves are a major problem in dairy and beef herds, with potentially a heavy economic impact. It is a multifactorial problem, and the most common post-mortem diagnosis in calves in first months of age.

Bovine coronavirus (BCoVs) infects the upper and the lower respiratory tract and the intestine. Besides digestive syndromes, BCoVs is known to cause respiratory disease in 2-weeks- to 6-months-old calves and be part of the bovine respiratory complex in feedlot cattle.

The aim of this study is to investigate the implication of BCoVs in pneumonia in Belgian calves on the basis of a case/control study.

Materials and Methods: The study has been performed on a panel of calves standardly autopsied in ARSIA (Regional laboratory specialized in animal health, Ciney, Belgium). The case group includes 115 animals showing respiratory lesions (red and/or grey hepatization, emphysema, abscess, pleurisy, tracheal lesions). The control group involves 49 animals showing no macroscopic pulmonary lesions at necropsy. Calves were aged from 1 week to 6 months.

For each calf, lung was sampled and submitted to various tests : (I) culture on classical media, (II) antigen ELISA for detection of Mycoplasma bovis, Bovine Respiratory Syncytial Virus (BRSV) and Parainfluenza-3 virus (PI-3) (Bio-X), (III) real-time PCR for detection of Coronavirus (LSI VetMAX™ Triplex Ruminant Rotavirus-Coronavirus, Thermo Fisher Scientific) and other pathogens (Mycoplasma bovis, Histophilus somni, Pasteurella multocida, Mannheimia haemolytica, BRSV, Bovine Viral Diarrhea virus, Bovine Herpesvirus type 4 – Thermo Fisher Scientific kits). Any real-time PCR result was considered positive if the cycle threshold (Ct) was inferior to 45; any result with non-conforming internal positive control was excluded from data analysis.

A histopathological study was led on 59 lungs (40 with macroscopic lesions, 19 without).

Faeces of calves were tested with bovine Coronavirus ELISA kit (Bio-X).

Results: About 24,55% (27/146) of the tested calves (displaying or not macroscopic lesions) were shedding BCoVs in their lungs upon

real-time PCR results. There was no significant difference between prevalences in case (21,69%) and control (33,33%) groups (Chi-square test : $p > 0,20$). Ct values of the positive results were relatively high (mean = 34,95). When lowering the positivity threshold of real-time PCR test at 30, no positive result was present in the control population and only one positive result (Ct,27,39) was seen in calves showing respiratory lesions (1/146, soit 0,68%). At necropsy, this 22 days old calf was exhibiting red hepatization of the lung. No other respiratory pathogens could be detected in the lung. Diarrhea was also reported but without BCoV detected in faeces.

In calves showing lesions and harbouring BCOVs, the virus was associated with one or more other respiratory pathogens in 96,77% of the cases. There was no significant association between BCOVs and other respiratory pathogens.

On the basis of the histopathological examination, there was no significant difference (Fisher's exact test: $p = 0,63$) in percentages of positivity between calves showing microscopic lesions with a viral pattern in the lungs (18,18%) and calves without viral inflammatory lesions (12,5%).

There was no correlation between BCOVs detection in faeces and its detection in lungs ($\kappa = 0,018$).

Conclusions: In the context of this case/control study, BCOVs, alone, doesn't seem to be a major pathogenic agent in calf pneumonia in Belgium. A large percentage of calves were harbouring BCOVs in lower respiratory tract without pulmonary disease. The exact role of this virus in bovine respiratory disease is not fully understood though it is known that co-infection with different pathogens, environmental factors and/or host health influence its implication.

Metabolomic analysis of calf serum after being fed colostrum

Tamako Miyazaki¹; Keiji Okada¹; Shigeru Sato¹; Tetsuro Yamashita¹; Masao Miyazaki¹

¹Iwate University, Morioka, Iwate, Japan

Objectives: Calves obtain nutrients and immunoglobulins (Ig) from colostrum. The amount of IgG increases after the intake of colostrum until 24 h after birth. Since this increase in IgG is accompanied by increased levels of other milk proteins in serum, we hypothesize that there may exist mechanisms for the non-specific absorption of intact proteins without degradation in the intestine. If this hypothesis is valid, the serum levels of low-molecular weight compounds derived from colostrum should increase after the intake. Here we examined temporal changes in the concentrations of low-molecular weight compounds in serum from calves that were fed colostrum.

Materials and Methods: Serum samples were collected from five male Holstein-Friesian calves for 12 h after being initially fed colostrum of 4% body weight at once by themselves within 6 h after birth. Serum proteins were analyzed by SDS-PAGE under non-reducing conditions. Acetone extracts of their serum samples were dried using a spin drier and derivatized with MSTFA. The samples were analyzed in triplicate using two dimensional gas chromatography (GC)-time of flight (TOF)-mass spectrometry (MS) (Pegasus 4D, LECO). ChromaTOF software (LECO) with analyte detectability and statistical comparisons was used to evaluate the differences between sample groups. Statistical analysis software was used for the multi-variable analyses, including principal

component analysis and cluster analysis, in order to identify organic compounds undergoing in temporal changes in concentration after colostrum feeding.

Results: SDS-PAGE showed a drastic change in a coomassie brilliant blue (CBB) stained band corresponding to IgG after feeding with colostrum. In addition to temporal changes in IgG levels, there were only a few changes visible in GC-MS total ion chromatograms after feeding. However about 2500 peaks were identified from each sample and the variation between samples aligned to over 4000 peaks. Fisher ratio of 100 narrowed these peaks to about 300 peaks. Several compounds in the serum, categorized into sugars, amino acids, and fatty acids, were identified and varied before and after feeding. Temporal changes in the concentrations of some of these compounds correlated with that of IgG.

Conclusions: This study demonstrates that changes occur in the metabolomic patterns of low-molecular weight organic compounds in calf serum after being fed colostrum. These changes do not correlate with protein absorption. We propose that proteins are not non-specifically absorbed along with low-molecular weight organic compounds, but are rather absorbed selectively via the intestinal epithelium of neonatal calves.

Potential benefits of acidification when feeding waste milk to calves

Roger Blowey^{1,1}; Jack Griffiths¹

¹Gloucester Vet, Gloucester, United Kingdom

Objectives: In the UK waste milk is defined as milk from cows in the first few days of lactation; milk from cows under treatment, milk from cows with mastitis and other conditions requiring a drug withhold period. The risks of feeding of waste milk include a high bacterial count leading to digestive upsets; the potential spread of Johnes (MAP), TB, and Mycoplasma; possibly increasing the risk of mastitis when they are heifers; and the potential risk of antibiotic resistance. Many of the risks can be inexpensively reduced or eliminated by acidification with formic acid, the effectiveness of which was the objective of the current study.

Materials and Methods: In a Johnes positive 600 cow dairy herd rearing its own replacements, heifer calves were originally fed calf milk replacer as a Johnes control measure, the waste milk going to male calves reared for beef. However it was noted that growth rates and disease levels were better in the male calves. Since 2009 acidified waste milk has been fed to all calves, including waste milk from Johnes positive cows. Formic acid is diluted 1:10 parts of water, then 30ml is added to one litre of milk to reach a pH of 4.0 and the milk left to stand for 48 hours with occasional stirring as described by Anderson (2008). When these calves enter the dairy herd as cows they are serological screened and ELISA tested at the end of each lactation. Positive cows are given a red ear tag, served with beef semen and culled early.

Results: The prevalence of seropositive cows originating from calves ($n = 311$), fed milk replacer was compared to cows originating from calves ($n = 134$) fed on purely acidified waste milk. The apparent prevalence of Johnes's positive cows was 13.83% with milk replacer (mean parity 3.17) compared to 1.50% prevalence with acidified milk (mean parity 1.66). The difference was statistically significant to a 95% confidence level with a p-value of 0.002. In addition there was a 26% reduction in the number of calves treated for pneumonia, and a reduction in the number of calves

A PRODUCTIVE
HERD NEEDS
LUSH PASTURES.
AND OUR SCIENCE.

When it comes to maintaining milk and meat yields, prevention is definitely better than cure. MSD Animal Health vaccines are at the forefront of protecting cattle herds from diseases that seriously affect yields. Our BOVILIS BVD, for control of bovine viral diarrhoea, is now one of the most important vaccines for dairy cattle in Europe. By heading off some of the most virulent infectious diseases, MSD Animal Health are helping farmers safeguard the reliability of the world's milk and meat supplies.

THE SCIENCE OF HEALTHIER ANIMALS™

treated for diarrhoea from 18% of calves treated in 2008/2009 to 6% in 2010/2011. Estimates of waste milk are estimated to be 1.5% of total output, eg 1.5% of 7000 litres = 100 litres/cow/year, plus discard from the first 6 milkings, eg 25 litres/day for 3 days = 75 litres. Waste milk is also of higher quality than calf milk replacer. The financial and environmental savings are therefore considerable

Conclusions: Although this study shows a reduction in the apparent prevalence of Johnes, it should be noted that the mean age of the milk replacer group (3.17) was higher than the acid milk group (1.66), and it would be expected that the prevalence of ELISA positive animals would increase with increasing age. There was also no direct control group, i.e. no animals fed milk replacer at the same time as the acid milk. However the results do show that there is no evidence of any increase in Johnes positive cows despite waste milk from Johnes positive animals being fed to calves.

Study of main enteropathogens associated with *Cryptosporidium* during diarrhea in calves

Júlia Gomes De Carvalho ¹Filipe L. M. Mendonça ¹Leticia C. Vespasiano ¹Fernanda M. Coura ¹Gustavo Henrique F. A. Moreira ¹

¹Clínica e cirurgia veterinária, Federal University of Minas Gerais, Belo Horizonte, Brazil

Objectives: *Cryptosporidium* is one of the main etiologies of diarrhea in newborn calves, mixed infections are commonly found. The aim of this study was to evaluate the main enteropathogens associated with *Cryptosporidium* spp. in newborn calves with diarrhea under different feeding strategies.

Materials and Methods: A total of 17 newborn male calves Holstein divided into two groups, 8 calves in group 1, fed 4 liters of milk replacer per day and 9 calves in group 2, receiving 6 liters. From the first day of life, the feces of calves were evaluated daily after breastfeeding in the morning and classified as diarrhea or no diarrhea. The first day of diarrhea until the seventh, feces were collected on alternate days (1, 3, 5 and 7 days). Qualitative research of oocytes of *Cryptosporidium* spp was performed by centrifugal sedimentation method in water-ether and modified Ziehl-Neelsen staining; qualitative research of *Giardia* sp. through concentration by centrifugal flotation in saturated solution of sucrose; isolation and PCR to identification of *Salmonella* spp. and pathotypes of *E. coli* and identification of Rotavirus by standard technique of polyacrylamide gel electrophoresis.

Results: All calves had diarrhea during the collection period. The average age of the beginning of the observed diarrhea in group 1 and 2 was 5.87 and 5.11 days of life, respectively. The association *Cryptosporidium* spp. with other agents was observed in 62% of positive samples, and these, 41% were associated with *E. coli* pathotypes, 35% with *Salmonella* spp., 18% with *Giardia* and 6% with Rotavirus in group 1. In Group 2, it was found 71% associated with *Salmonella* spp., 21% with *Giardia* sp. and 7% with Rotavirus.

Conclusions: Although the literature demonstrate Rotavirus as the most common agent associated with *Cryptosporidium* spp., the association between *Cryptosporidium* spp. and bacteria was the most common in both groups, such fact may be related to environmental conditions conducive to maintaining high bacterial load.

Evaluation of factors affecting overall colostrum quality and passive transfer of immunity to calves using a Brix refractometer

A. Soufleri ¹N. Panousis ¹G. Banos ¹D. Fletouris ¹G. Arsenos ¹G. E. Valergakis ¹

¹Faculty of Veterinary Medicine, Aristotle University of Thessaloniki, Thessaloniki, Greece, ²Scotland's Rural College/Roslin Institute, Edinburgh, Scotland, United Kingdom

Objectives: Brix refractometers are inexpensive, easy to use and quick cow-side tools for the indirect assessment of colostrum quality (CQ) and passive transfer of immunity (PTI); however, factors affecting the latter have not been evaluated in large scale studies using this method. The objective of the study was the evaluation of factors affecting overall CQ and passive transfer of immunity to newborn calves using a Brix refractometer (BR).

Materials and Methods: The study was conducted in 9 commercial dairy herds in Northern Greece from February to October 2015. 560 Holstein cows and 510 calves were used. Each cow was blood sampled the 1st day post calving and the percentage (%) of serum total protein (sTP) was measured within 3 hours using a digital BR. Cows were milked completely 2-8 hours after calving, colostrum quantity recorded and 2 samples were collected from each cow: one was used to measure % of total solids cow-side, using the same BR; the 2nd sample was transferred to the laboratory and analyzed for fat, protein and carbohydrate content with the use of Milkoscan. Quantity of 1st colostrum meal fed to each calf and time interval between calving and 1st meal was recorded. Calves were blood sampled between 24-48 hours post-calving and % of sTP was measured within 3 hours using the BR. Data of colostrum quantity were analyzed with a univariate general linear model (UGLM); season and time interval between calving and colostrum collection were set as fixed effects. Brix measurements were analyzed with UGLM. For colostrum, the model included season, time interval between calving and colostrum collection, quantity of colostrum produced and cows' sTP as fixed effects. For calf serum it included, season, colostrum quantity and quality fed, time interval between calving and 1st colostrum meal and cows' sTP as fixed effects. Correlations between colostrum fat, protein and carbohydrate content, and Brix scores for colostrum and cow serum measurements were estimated with bivariate analysis (correlation coefficient by Pearson).

Results: The average Brix scores for colostrum, cow serum and calf serum were 25.5±4.5%, 9.5±0.7% and 8.8±1.2%, respectively. Season and time interval between calving and colostrum collection had a significant effect on colostrum quantity produced (P<0.05); the latter being lowest in autumn and when time interval was short. Season, time interval between calving and colostrum collection and quantity of produced colostrum had a significant effect on CQ (P<0.05). The latter was higher in spring, when the interval between calving and colostrum collection was short and when the quantity produced was low. The effect of cow sTP content on colostrum quality was not significant (P>0.05). Colostrum quantity and CQ fed had a significant effect (P<0.05) on calf serum Brix scores, with highest quality and quantity resulting in better PTI. The effect of season, time interval between calving and 1st colostrum meal and cow sTP content were not significant (P>0.05) for PTI. Colostrum fat and protein content were negatively correlated (P<0.05) with quantity produced (r=-0.105 and r=-0.211, respectively), but positively correlated (P<0.05) with Brix scores (r=0.173 and r=0.926, respectively). Colostrum carbohydrate content had a statistically significant (P<0.05) positive correlation with

colostrum quantity produced ($r=0.109$) and a statistically significant negative correlation with Brix colostrum measurement ($r=-0.434$). Colostrum protein content was also positively correlated with total protein measured by Brix in cow serum ($r=0.103$).

Conclusions: Factors known to affect CQ and PTI were confirmed using Brix refractometer scores. In calves, CQ and quantity fed had a significant effect on PTI. In cows, serum total proteins affect colostrum protein content but neither colostrum quality nor PTI, as assessed by Brix refractometry.

P04-004-166

Longitudinal study of naturally occurring rotavirus diarrhea in a vaccinated and a non-vaccinated dairy herd in Sao Paulo State - Brazil

Thais Rocha¹·Fernanda D. F. Silva²Fabio Gregory²Maria da Gloria Buzinaro³Jose Jurandir Fagliari¹

¹Veterinary Clinic and Surgery, FCAV-Unesp, Jaboticabal, ²Applied Molecular Biology and Serology Laboratory, University of Sao Paulo, Sao Paulo, ³Preventive Veterinary Medicine, FCAV-Unesp, Jaboticabal, Brazil

Objectives: The aim of the present study was to evaluate diarrhea characteristics and identify VP7 (G) and VP4 (P) genotypes of bovine group A rotavirus (BRV-A) from a vaccinated and a non-vaccinated dairy herd from Sao Paulo State, Brazil.

Materials and Methods: Animals belonging to a herd that regularly vaccinated the dams according to manufacturer's instructions with a commercial vaccine containing strains G6P[1] and G10P[11] of inactivated BRV-A (group V), and cows from a herd that was not regularly vaccinated against rotavirus diarrhea (group NV) were evaluated in a longitudinal design study. Colostrum management consisted of bottle feeding at least 4 liters of their own mother's colostrum to calves up to two hours after birth. Fifty six Holstein calves, 28 from group V, and 28 from group NV were evaluated from birth to 30 days of age. Fecal samples were taken directly from rectum using individual plastic bags before colostrum intake (0), and with 1, 2, 7, 15, 21, and 30 days of age and frozen at -20°C until analysis. Whenever calves presented diarrhea, fecal samples were taken at 24 hour intervals until the end of clinical signs. Fecal samples were classified in scores: 0 (firm feces), 1 (slightly loose feces), 2 (loose feces), and 3 (watery feces). Scores 0 and 1 were considered normal feces and scores 2 and 3 were considered diarrhea. Rotavirus detection in feces was performed using 7.5% polyacrylamide gel electrophoresis technique. The polymerase chain reaction (PCR) preceded by reverse-transcription (RT) of viral RNA was employed to characterize bovine rotavirus genotypes G (VP7) and P (VP4) using primers already reported. First round PCR products were subjected to bidirectional sequencing and analyzed with Neighbor-Joining algorithm, Maximum Composite Likelihood as substitution model, and 1,000 bootstrap replicates.

Results: A total of 561 fecal samples were taken from calves from birth to 30 days of age, 281 from group V, and 280 from group NV. In group V, 211 (75.1%) fecal samples were considered normal (scores 0 and 1) and 70 (24.9%) fecal samples were considered diarrheic. In group NV 212 (75.7%) fecal samples were considered normal and 68 (24.2%) were considered diarrheic. Group V comprised eleven samples originating from six different calves that tested positive

for BRV-A detection in feces by PAGE technique; while group NV comprised three samples originating from three different calves that tested positive for BRV-A. Although positive samples were found in both normal ($n=5$) and diarrheic feces ($n=9$), all calves that tested positive for BRV-A detection in feces presented an episode of diarrhea in the first 30 days of life. Bovine RVAs analyzed in this study showed G/P-genotypes of G6P[11] from group V and G6P[5] from group NV. Regarding calves age, none of the calves that tested positive for BRV-A in feces were aged between 1 and 7 days of life. Calves that tested positive rotavirus in feces were in their second ($n=2$) or third weeks of age ($n=4$) in group V and in their second ($n=2$) and fourth ($n=1$) weeks of life in group NV.

Conclusions: All calves infected by rotavirus presented diarrhea episode in the first month of life. Vaccination of herds may induce genetic reassortment of the virus, as seen by the genotype of rotavirus found in the calves born to vaccinated dams. Commercial vaccines currently used are not designed for the prevention of rotavirus infection, but rather to decrease morbidity, severity of diarrhea and mortality in field conditions, which, does not reduce the expenses of treatment aiming to avoid secondary bacterial infections and still impacts on the potential development and performance of calves in their productive life.

Comments: Authors thank Fundação de Amparo à Pesquisa do Estado de São Paulo (FAPESP) for the financial support and scholarships granted (Processes 2010/10677-0 and 2011/02414-1)

Chronic herd health problems in Germany: Description of symptoms on herd level and risk factor analyses

Katharina Charlotte Jensen ^{1,2,*}, Martina Hoedemaker ¹, Cornelia Frömke ², Theresa Scheu ¹, Anika Wichern ¹, Svenja Fohler ³, Christian Seyboldt ⁴, Lothar Kreienbrock ², Amely Campe ²

¹Clinic for Cattle, ²Institute for Biometry, Epidemiology and Information Processing, ³Institute for Food Quality and Food Safety, University of Veterinary Medicine Hannover, Hannover, ⁴Institute of Bacterial Infections and Zoonoses, Friedrich-Loeffler-Institute, Jena, Germany

Objectives: In the last two decades, chronic herd health problems in dairy herds accompanied by economic losses and a compromised animal welfare have been reported in Germany. First, a causal relationship with *Clostridium botulinum* was suggested. However, *C. botulinum* could not be proven to be the main exposition factor. Therefore, the causes of the ongoing herd health problems remain unclear. Hence, the objectives of this presentation are (I) to describe the clinical symptoms systematically on herd level and (II) to identify risk factors from various fields including housing, hygiene, feeding, infectious diseases and claw care.

Materials and Methods: To examine the herd health problems, a case-control study was conducted. Due to the unspecific clinical picture, case-farms had to fulfill at least three of the following five criteria: decreased milk yield, increased mortality, increased culling rate, increased number of downer cows and the farmers' impression of herd health problems. Control farms (n=47) did not fulfill any of these criteria. Case 1-farms (C1, no vaccination against any Clostridia; n=45) and case 2-farms (C2, multi-clostridia-vaccination was applied; n=47) were compared to control-farms, separately. During a single farm visit, trained study veterinarians scored the herd with regard to cow-comfort, locomotion, body condition, hygiene, and skin lesions. Moreover, an interview was held with the herd manager, housing conditions and feeds were assessed and ten cows were examined thoroughly.

Results: A combination of symptoms from all analyzed fields except udder health showed a significant relation to the case-control status. Multifactorial logistic regression modeling revealed that case-farms had significantly fewer cows with high body condition scores (C1: $p=0.0102$, C2: $p=0.0041$), more cows with skin lesions on legs (C1: $p=0.0400$, C2: $p=0.0054$), and a lower cow-comfort-quotient than control-farms (C1: $p=0.0095$, C2: $p=0.0048$). Moreover, case 1-farms had a longer calving interval ($p=0.0120$), and more often a deficient cow hygiene ($p=0.0419$) than control farms. Case 2-farms had a lower cud-chewing-index than control-farms ($p=0.0282$).

Concerning the risk factor analyses, both types of case farms had a lower energy density in the roughage for fresh lactating cows (C1: $p=0.0088$, C2: $p=0.0052$). Case 1-farms had more often lying areas in worse hygienic conditions ($p=0.0114$) and were more likely to have an intermediate animal-watering place-ratio ($p=0.0303$) compared to control farms. Case 2-farms had more often raised cubicles instead of cubicles with deep beddings or straw yards ($p=0.0031$), were more likely to have at least one silage with microbiological deviations ($p=0.0170$), and had smaller herds (confounder, $p=0.0290$) compared to control farms. Differently than expected, case 2-farms were less likely to have at least one grass silage with a true protein fraction <50% of crude protein ($p=0.0112$) and performed herd claw trimming more frequently twice a year ($p=0.0220$). Perhaps, farmers had already increased claw trimming frequency due to the high incidence of lameness.

Conclusions: The detected symptoms confirm that herd health problems were unspecific but yielded important knowledge about the problems case-farms had. This knowledge should be used in the future to adjust consultancy to these well-known but still relevant problems.

It can be concluded that feeding (in particular the energy density and the quality of silages), resting areas and hygiene presumably play an important role. It does not seem that there is the one and only factor responsible for chronic herd health problems in Northern Germany. However, we conclude that no field should be neglected when herd health problems have to be solved.

Abortion/Stillbirth Investigation

Evidence of exposure to pathogens in stillborn calves on Polish dairy farms - preliminary results

Paulina Jawor ^{1,*}, Dawid Król ¹, Zenon Sołtysiak ², Edyta Żyromska ¹, Stanisław Dzimira ³, Magdalena Laska ⁴, John F. Mee ⁵, Tadeusz Stefaniak ¹

¹Department of Immunology, Pathophysiology and Veterinary Preventive Medicine, ²Department of Internal Medicine and Clinic of Diseases of Horses, Dogs and Cats, ³Department of Pathology, Wrocław University of Environmental and Life Sciences, Wrocław, ⁴Department of Virology, National Veterinary Research Institute, Puławy, Poland, ⁵Animal and Bioscience Research Department, Teagasc, Moorepark Research Centre, Fermoy, Ireland

Objectives: Calves born dead after a gestation period of ≥260 days or within 24 hours of birth may be considered stillborn (SB). The causes of SB are multifactorial and may differ between herds and between countries internationally. Numerous infectious causes of bovine stillbirth have been documented. Compared to abortion (birth of a non-independently viable fetus pre-term) infection is less commonly diagnosed in SB calves. There are no published data regarding the occurrence of intrauterine infection in SB calves in dairy cattle in Poland. Therefore the aim of this study was to investigate the prevalence of intrauterine infections in stillborn calves.

Materials and Methods: The study was carried out on 121 SB calves (as defined above), born from November 2013 to June 2015 in 30 Polish Holstein-Friesian herds (1-1,031 cows/herd; 1-35 SB/herd). None of the calves received colostrum. A complete necropsy was performed on each carcass. During the necropsy an ear sample, blood for plasma, nine internal organs (spleen, liver, lung, small intestine, kidney, adrenal glands, heart, brain) and abomasal contents were sampled. The placenta was also sampled. Samples from all internal organs and the placentae were cultured in aerobic (for routine culture and *Salmonella spp.*), anaerobic and microaerobic conditions. The ear samples were tested for Bovine viral diarrhoea virus (BVDV) antigen (ELISA). Sections of inner organs were tested using real time PCR to detect *Neospora caninum*, Schmallenberg virus (SBV) in brain, Bovine herpesvirus type 1 (BHV-1) in liver and pathogenic *Leptospira spp.* in kidney. Additionally, sections of brain were examined histologically. Foetal blood plasma was tested for antibodies to *Neospora caninum*, BHV-1, BVDV, SBV (ELISA) and *Leptospira hardjo* and *L. pomona* (microagglutination test).

Results: No primary bacteria were cultured from the internal organs, abomasal contents or placentae. In two calves, an abundant growth of *E. coli* (1 case) or *Enterococcus faecalis* (1 case) from all internal organs was observed. One calf was positive for BVDV (ear biopsies). All real-time PCR results were negative. Antibodies were detected to: BVDV (4 cases), *N. caninum* (5 cases), SBV (5 cases), *L. hardjo* (1:100-3 cases, 1:400-1 calf), *L. pomona* (1:100-1 case, which had antibody for *L. hardjo* as well). Antibodies to BHV-1 were not detected. Of the 90 brains examined *N. caninum* cysts were detected in 7 calves (one of which also had antibodies to *N. caninum*).

Conclusions: This study demonstrated that previous exposure to pathogenic infectious agents, as evidenced by the detection of a humoral immune response, was uncommon (~15% of SB) and that evidence of infection was even less common (~6% of SB) in Polish dairy herds.

Abortion/Stillbirth Investigation

P04-004-007

Differentiation of acute intrauterine infection from other causes of death in bovine perinatal mortality using SAA and IgM concentrations.

Paulina Jawor ^{1,*}, Tadeusz Stefaniak ¹, John F. Mee ²

¹Department of Immunology, Pathophysiology and Veterinary Preventive Medicine, Wrocław University of Environmental and Life Sciences, Wrocław, Poland, ²Animal and Bioscience Research Department, Teagasc, Moorepark Research Centre, Fermoy, Ireland

Objectives: Bovine stillbirth may be defined as calf death at full term (>260 days) prior to, during, or within 48 h of calving. The unexplained stillbirth (approximately 30% of all deaths) is a diagnostic challenge for veterinary practitioners and for laboratory diagnosticians. The high rate of unexplained stillbirths in calves may, in part, be the consequence of too narrow a spectrum of diagnostic methods applied. The objective of this study was to determine diagnostic threshold for immuno-inflammatory biomarkers in stillborn calves diagnosed with intrauterine infection (bacterial, viral or parasitological) compared to traumotocia and unexplained cases.

Materials and Methods: The 110 calves were from perinatal mortality necropsy cases from Irish dairy farms in 2011-2013. These were full-term (>260 days of gestation), died within one hour of birth but did not consume colostrum. Four diagnostic groups were compared: acute intrauterine infection (INF_A; n=16), chronic intrauterine infection (INF_CH; n=31), traumotocia (TRAUM; n=22) and unexplained death (UNEXPL; n=41). In the INF_A group there was detection of: *Bacillus licheniformis* (5 cases), *Salmonella Dublin* (7 cases), *Trueperella pyogenes* (3 cases) or *Listeria monocytogenes* (1 case). In the INF_CH group there was: BVD virus (7 cases), *Neospora caninum* (6 cases) or Schmallenberg virus foetopathy (18 cases). In the TRAUM group there were detection of severe antemortem lesions consistent with iatrogenic parturient trauma at assisted calvings. The case inclusion criteria for the UNEXPL group were failure to fulfill the inclusion criteria of the other three groups.

Plasma was analyzed for serum amyloid A (SAA), (ELISA), haptoglobin (Hp), (microplate guaiacol method or ELISA) and immunoglobulins M (IgM) and G1 (IgG1), (both ELISA).

A logistic regression model –was used to evaluate which parameter - SAA, Hp, IgM and IgG1 would discriminate acute infection from other COD categories. An ROC analysis was used to evaluate the ability of parameters to discriminate between acute infection and other COD.

Results: The mean (sem) concentrations of SAA (mg/L), and IgM (mg/L) were numerically higher in the INF_A [SAA 53.3 (16.5), IgM 370.3 (144.7)] compared to the INF_CH [SAA 19.6 (10.1), IgM 86.1 (31.0)], TRAUM [SAA 11.9 (2.4), IgM 81.5 (40.4)] and UNEXPL groups [SAA 10.7 (3.0), IgM 134.2 (49.2)]. SAA concentrations in INF_A group were significantly higher than in UN group ($P=0.04$) and tended to be significantly higher than in INF_CH ($P=0.06$). IgM tended to be significantly higher in INF_A compared to TRAUM ($P=0.051$) and compared to INF_CH ($P=0.09$). Hp and IgG1 values were not significantly different ($P>0.05$) between the groups. The logistic regression model showed that SAA and IgM, but not Hp and IgG1, values could significantly differentiate acute infection from other COD. The area under curve for SAA was 0.705 (95% CI 0.533-0.877, $P=0.02$), and IgM 0.719 (95% CI 0.579-0.858, $P=0.002$). The optimal threshold for diagnosis of acute infection in stillborn calves was ≥29.5mg/L for SAA (Sensitivity=0.56, Specificity=0.91) and ≥52.1 mg/l for IgM (Sensitivity=0.75, Specificity=0.68).

Conclusions: The SAA and IgM concentrations were higher in stillborn calves with acute infection compared to other causes of death. The concentration of SAA and IgM at/above diagnostic thresholds with highest combined sensitivity and specificity may be useful in detecting bacterial infections in stillborn calves. This is the first report which shows that these immune-inflammatory biomarkers can differentiate acute intrauterine infection from others causes of death.

velactis[®]

DRY OFF

MANAGEMENT

UDDER HEALTH

WELFARE

Velactis 1.12 mg/ml solution for injection. Each ml contains Cabergoline 1.12 mg. Indications. For use in the herd management programme of dairy cows as an aid in the abrupt drying-off by reducing milk production to: reduce milk leakage at drying off, reduce the risk of new intramammary infections during the dry period and reduce discomfort. Special warnings. Velactis should be used as part of a comprehensive mastitis and milk quality control program under veterinarian advice, which might include the need to use intramammary treatment. Dosage and administration. Intramuscular use. The recommended dose is 5.6 mg of cabergoline (corresponding to 5 ml of solution for injection) per animal in one single injection at the day of drying-off after the last milking. The product should be administered within 4 hours after the last milking. Withdrawal period(s). Meat and offal: 23 days. Milk: Zero hours after calving when the dry period length is 32 days or more. 4 days (8 milkings) after calving when the dry period length is less than 32 days. Ceva Santé Animale, 10 av. de La Ballastière, 33500 Libourne, FRANCE. MA. EU/2/15/192/001-004

MAKE BVD HISTORY

AN INNOVATIVE SOLUTION

NOW IN YOUR HANDS

Bovela brings innovation to BVD protection: a L2D (live double deleted) BVD vaccine providing 12 months protection against both BVDV types 1 and 2 from a single shot. Bovela prevents the birth of persistently infected (PI) calves caused by transplacental infection.

Vaccination with Bovela can be done from 3 months of age. So now you can finally help your clients **make BVD history**.

BOVELA

Herd protection made simple
